21404—February 24—Further extending until May 31st, 1914, the time within which sidings for the Otis-Fensom Elevator Co., at Hamilton, Ont., be constructed and completed.

21405—February 26—Further extending until June 30th, 1914, the time within which to complete the sidings for the Godson Contracting Co., in Lot No. 16, Con. 19, Twp. Darlington, Ont.

21406—February 24—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway, or spur, for the International Harvester Co., Lethbridge, Alta., from a point on the westerly limit of the C.P.R. Alta. Division, thence across Tenth Avenue, West, and along lane 206 in said City of Lethbridge.

21407—February 24—Authorizing the C.P.R. to construct, maintain, and operate an extension to siding for the C. S. Hyman Co., Ltmited, on Subdiv. Lots 3, 4, and 5, Block 304 A, London, Ont.

21408—February 26—Authorizing the Twp. of McKim, at its own expense, to construct and maintain highway crossing over the tracks of the C.P.R. in Lot 9, Con. 5, Twp. of McKim.

21409—February 26—Limiting the speed of trains over the crossing of Long St., by the G.T.R., at Chesley, to a rate not exceeding ten miles an hour.

21410—February 24—Authorizing the G.T.R. to construct, maintain, and operate extension of siding serving the premises of the British American Oil Co., Limited, commencing at a point on the G.T.R. tracks on the 150-foot roadway reservation, north of Keating's Channel, Ashbridge's Bay, Toronto, Ont., thence extending in a westerly direction to and into part of Block E, leased to B. A. Oil Co., Limited.

21411—February 24—Authorizing the G.T.R. to construct, maintain and operate branch line of railway, or siding, commencing at a point on the N. Div. of its railway on Lot 8, in the 1st Con. of Twp. of Chaffey, Dist. of Muskoka, Ont., and near Huntsville Station, thence extending in a northeasterly direction to and into the premises of Steven Brothers and Holmes, Brick Mnfs., on said Lot 8, thence extending easterly and adjoining the G.T.R. railway on said Lot 8.

21412—February 24—Authorizing C.N.R. to construct, maintain and operate a spur to serve the Alberta Agencies in Block 22, Glenora Subdiv., crossing Coot Street, Edmonton, Alta.

A weekly paper for engineers and engineering-contractors

SASKATCHEWAN RIVER IN MANITOBA

ITS TRIBUTE TO THE AVAILABLE POWER RESOURCES OF THE PROVINCE, AS REPORTED BY THE WATER POWER BRANCH, DEPARTMENT OF THE INTERIOR, TO THE PUBLIC UTILITIES COMMISSION.

THE Saskatchewan River enters Manitoba from the west, crossing the boundary between Saskatchewan and Manitoba almost directly opposite the north end of Lake Winnipeg. It enters the lake some 50 miles south of the lake's northerly end.

The area drained by the Saskatchewan River is in extent approximately 155,000 square miles, comprising a great portion of the western plains. The headwaters lie in the Rocky Mountains, and the drainage, though collected by many tributaries, is carried across the prairies by two large rivers known as the North and South Saskatchewan. The north branch heads in the Rockies west of Edmonton, while the southern branch heads in the same mountain range approximately on a line west of Medicine Hat. Intermediate between these two branches is situated the Red Deer River, a stream of almost as great an extent as the southern branch which it joins. The distance between the two rivers gradually diminishes with a consequent contraction of the drainage until about 30 miles below Prince Albert the junction of the north and south branches occurs. From the junction to Lake Winnipeg the flow is mostly confined to a single bed although in places it is divided into main and secondary channels, as at the Sepannock Channel, due to the generally flat and low-lying nature of the country, and to the consequent ease with which the river can and does at times change its bed. In Manitoba the river flows through a low-lying region in which occurs innumerable lakes and swamps. Great portions of the surrounding land are subject to floods during periods of high water. In the vicinity of Lake Winnipeg the river enters Cedar Lake and discharges from this lake into Crodd Lake, the Demi Charge Rapids occurring in this

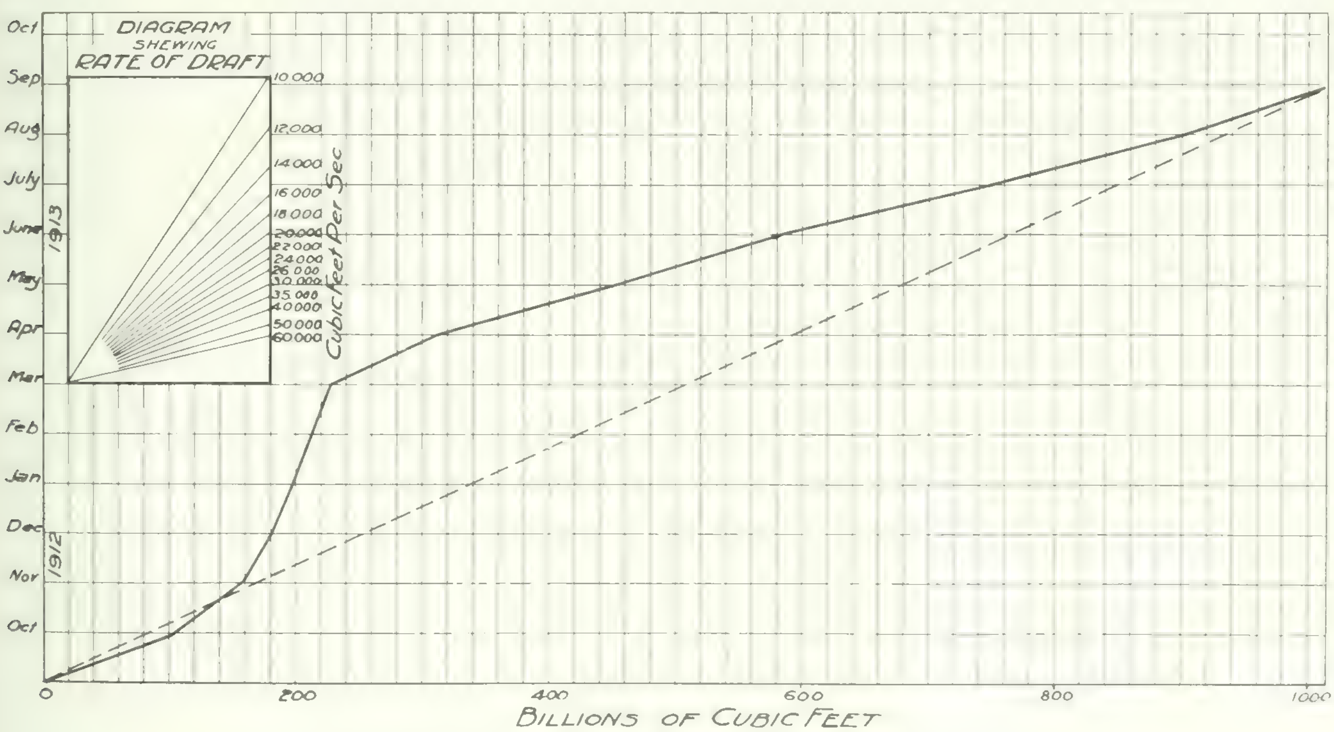

Fig. 1.—Mass Curve of Estimated Run-off, Saskatchewan River.

portion of the river. From Cross Lake to Lake Winnipeg a series of rapids occur comprising the Cross Lake rapids, Bed Rock Rapids and Grand Rapids.

Nature of the River and Banks.—In the vicinity of Le Pas, the banks range from 15 to 25 feet in height, but they become gradually lower as Cedar Lake is approached. The shores of this latter lake, as also the banks in the stretch of river to Cross Lake are rocky. From Cross Lake to the mouth of the river outcroppings of limestone occur at the water's edge. At Cross Lake Rapids this outcrop reaches a height of from 2 to 6 feet. In the vicinity of Red Rock Rapids the right bank is composed of limestone of some 6 feet in height, while the left shows no rock outcrops, being composed of clay and of some 12 feet in height. From Red Rock Rapids to Grand Rapids the banks, which are of clay, gradually become higher. At the latter rapids limestone is again encountered, rising in some places 30 feet above river level. A high ridge of lightly colored boulder clay overlying limestone rises to a height of some 60 feet about the mid point of Grand Rapids. This ridge which forms the barrier between Cedar Lake and Lake Winnipegosis crosses the Saskatchewan about three miles above the mouth. Near the foot of Grand Rapids a gully, which was probably as one time an overflow channel, sweeps inland from the left bank and returns to the main river a mile further down.

The river in Manitoba has an average width of about 1,000 feet; a minimum width of approximately 500 feet occurs in Grand Rapids, widening to 2,400 feet below the rapids. From the Manitoba boundary to Cedar Lake the river has a mud and gravel bottom with the occurrence of shifting bars. In the reaches below this section the bed of the river at various rapids is composed of limestone, while many beds of boulders occur in the intervening space.

A valuable timber growth occurs a slight distance above Le Pas, but from there to Cedar Lake the growth is stunted; and while a dense growth occurs around both Cedar and Cross Lakes, yet the timber occurring below this is largely of second growth.

High water usually comes during the months of July and August, while low water occurs in the winter months, the river reaching its lowest stage about the month of March. At Le Pas the range between these two periods is ordinarily some 15 feet, while at Grand Rapids the range is gradually lessened, being ordinarily from 4 to 5 feet with an extreme of some 6 feet. During the spring break-up the field ice of Lake Winnipeg occasionally becomes jammed at the mouth of the river, damming the outlet and causing a rise at the lake of from 12 to 15 feet.

The Saskatchewan is navigable above Grand Rapids, the Hudson's Bay Co. having at one period run steamers as far upstream as Edmonton. The river at present is navigated by gasoline launches from Le Pas to Cedar Lake. It is accessible by railroad at Le Pas and also by steamer at the mouth.

With the exception of Le Pas, no settlements of any size occur in the lower reaches of the river. A Hudson's Bay post is situated at Cedar Lake and a small settlement occurs at Grand Rapids.

Surveys of the River.—In 1884, Dr. Otto Klotz made a traverse of the river. The late R. E. Young made a survey of the settlement in the year 1903 and continued his traverse to the head of Grand Rapids, obtaining at the same time a profile of the portage. In 1909 a reconnaissance survey of the river was made from Le Pas to Lake Winnipeg by E. A. Forward, of the Public Works Department. The investigations made by the Water Power Branch of the Department of the Interior comprise a reconnaissance power survey by the late William Ogilvie in the year 1911, and in the following year a detailed survey of Grand Rapids and vicinity from Lake Winnipeg to Cross Lake. This latter survey was carried out by E. B. Patterson in charge of a field party of the Manitoba Power Survey. At the same time, a gauging station was established at Grand Rapids and discharge measurements were then and have since been obtained at this station.

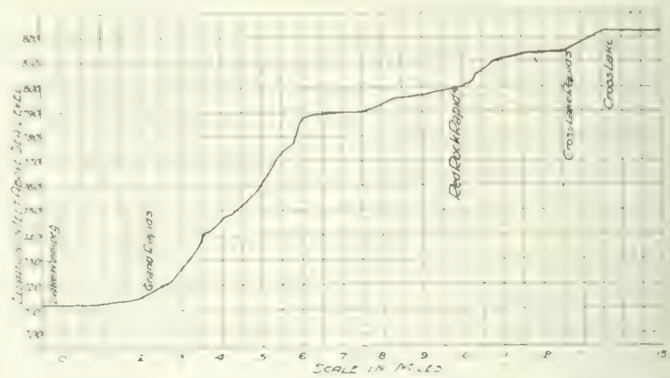

Fig. 2.—Profile of Saskatchewan River from Lake Winnipeg to Cross Lake.

Run-off.—No complete records are available for the precipitation in either the extreme western or eastern portion of the drainage. The following table, obtained from the meteorological records of Canada, gives the precipitation at various points throughout the central portion of the drainage, together with some few records of precipitation in the Rocky Mountains:—

Length of Record.

Station.	Period.	Beginning.	Depth, in inches.
Prince Albert	9 years	1903	17.13
Saskatoon	9 "	1904	14.45
McLeod	22 "	1884	12.58
Calgary	27 "	1885	15.17
Edmonton	28 "	1883	16.43
Banff	19 "	1891	20.3
Fort Dunvegan	4 "	1905	11.5

Float discharge measurements were made in the year 1909 by E. A. Forward at Le Pas, and also at Grand Rapids. This was followed by measurement made by the late William Ogilvie in the year 1911 at Grand Rapids. On August 8th, 1912, a gauging station was established at Grand Rapids by the Manitoba Hydrographic Survey, and on October 21st of the same year, a second station was established at Le Pas. It is estimated that for the year 1913, a low flow of 5,000 second-feet occurred during the month of February at Le Pas, and while several lakes and a great area of low-lying, swampy land occurs between this point and Grand Rapids which should give some regulation of the flow at the latter point, yet it has been assumed that a minimum flow of 5,000 second-feet also occurred at Grand Rapids. During July of 1913 a flood discharge of approximately 64,000 second-feet was recorded at Le Pas.

Storage Possibilities.—Three lakes are situated in the lower portion of the river system immediately above Grand Rapids; through two of these lakes—Ceder and Cross Lakes—the river flows, while Moose Lake is a tributary to the north. The combined area of these three lakes is estimated to be 970 square miles, being

made up as follows: Cross Lake, 39; Cedar Lake, 425, and Moose Lake, 513 square miles. While there might be a possibility of storage on these lakes, investigations are at present being made as to the reclamation of low lands in the vicinity of Cedar Lake through the lowering of the latter, which if carried out would forestall storage possibilities. Investigation is also being made as to the storage possibilities in the headwaters of the Saskatchewan River.

Making the assumption that the flow of the winter months from October 1st, 1913, to April 1st, 1914, would be similar to the same period during 1912-1913, mean curve studies (See Fig. 1) show that a storage of 305 billions of cubic feet would be necessary for a uniform flow of 32,000 second-feet. A 1-foot storage on Cross, Cedar and Moose Lakes would give approximately 27 billion cubic feet, indicating that a storage slightly over 10 feet would be necessary to create a uniform flow for a period similar to that found year ending September 30th, 1913.

Water Power.—An estimate of the power available at the three rapids, as indicated in Fig. 2, is given below. The power available has been based on a 80% efficiency and is also computed, 1st, for an estimated minimum flow of 5,000 second-feet, and 2nd, for a flow of 34,000 second-feet, this being the lowest monthly mean flow for the 6 highest months of the year ending September 30th, 1913, and extending from April to September, and the power as indicated refers only to this period.

No estimate has been made as to the additional power available during periods of low flow through any storage system:—

Estimated Horse-power on 80% Efficiency.

Possible power site.	Head in ft.	Minimum flow 5,000 sec.-ft.	Period 6 mos., April-Sept. 34,000 sec.-ft.
Demi Charge ..	15	6,808 h.p.	46,289 h.p.
Red Rock	15	6,808 h.p.	46,289 h.p.
Grand Rapids ..	80	36,305 h.p.	246,877 h.p.

Mayor Curley of Boston is advocating the consideration of the erection of a municipal asphalt and bitulithic paving plant, pointing out the significance of the fact that the Central Construction Company, which recently installed a plant for paving work, was the lowest bidder on work recently advertised by 10 per cent., bidding against one of the largest firms in the world.

In co-operation with Connecticut's plan for developing New London as an ocean port the United States War Department on January 19th recommended to Congress a channel 33 feet deep at mean low water and 600 feet wide, at an estimated cost of $330,000. The department recommended a first appropriation of $170,000 and a second of $160,000 to complete the work in two years, conditioned upon assurances that the State will carry out its terminal plans, for which it has already appropriated $1,000,000.

It has been reported at Buffalo that the Legislature proposes making an appropriation of $30,000 to cover the expense of a commission of 15 citizens who shall be known as the Peace Centenary Commission. The idea of the commission is to get up a plan for proper celebration of the 100 years' peace between the United States and other countries, barring Mexico. The project contemplated is the erection of a bridge which will connect Fort Erie and the Canadian border that shall be sufficiently large to accommodate the great traffic certain to use it.

THE DETERMINATION OF THE MAGNETIC DECLINATION, DIP AND TOTAL FORCE IN WESTERN CANADA.

Although the compass is not used in running lines on Dominion land surveys, it is a valuable accessory, especially in unexplored parts of the country. Where no line of definite bearing is available, it may be used advantageously as a finder of Polaris in daylight observations for azimuth. To accomplish this, however, a knowledge of the local magnetic declination is necessary; in other words, one must know within a reasonable degree of accuracy the angular interval between magnetic north and astronomic north.

The Topographical Surveys Branch, Department of the Interior published, in conjunction with the latest report of the Surveyor-General of Dominion Lands, a description of the determination of the magnetic declination, dip and total force in Western Canada, written by D. E. Chartrand, B.Sc., and reproduced in part as follows:—

The accurate determination of the magnetic elements in western Canada dates as far back as the year 1842, when Lieut. J. H. Lefroy, under the direction of the Royal Society, made a magnetic survey of that portion of the country. Magnetic observations were taken in the year 1887 by the Topographical Surveys Branch, but nothing further to any extent was done by it until 1908, when its Dominion land surveyors were instructed to observe the magnetic declination during the course of their surveys.

An isogonic map, on a very small scale, was published in 1904, chiefly from data obtained from Lefroy's survey and the 1887 observations of this Branch. Some information along the international boundary and around the Great Lakes was obtained from the United States Coast and Geodetic Survey.

In 1911 an isogonic map, on a very small scale, of that portion of Canada south of the 54th parallel of latitude was prepared and published in two sections, one for eastern Canada and the other for the western provinces. The declinations used for the western section were derived from the observations of this Branch. The sources of information for the compilation of the eastern section were: the Director of the Meteorological Service at Toronto, the British Admiralty charts, and the United States Coast and Geodetic Survey.

Area Covered.—As the survey operations under this Branch are confined entirely to the lands under the control of the Dominion government, the stations occupied since 1908 are limited to the provinces of Manitoba, Saskatchewan, Alberta and British Columbia. The districts where meridian, base line and subdivision surveys have been in operation since that date have been dotted with stations for the magnetic declination. A special effort has been made to gather magnetic data from the settled districts by means of travelling parties employed on miscellaneous surveys. These surveys generally cover a wide stretch of country and provide the only means now at our disposal of observing the magnetic elements in the settled parts of western Canada.

Compass Used for Declination.—The determination of the magnetic declination is made by means of a trough compass attached to the standards of the transit theodolite used on the Dominion land surveys. The needle is made as light as possible in order to reduce friction on the pivot to a minimum. The graduation of the end blocks consists of a single fine line, and readings are made on both ends of the needle. The range of readings of a first-class needle, well balanced, and in the hands

of a competent observer, can be expected not to exceed two minutes. The original method of attaching the compass to the standards consisted of a hook at one end and a thumb-screw at the other, but as this was not always found to be satisfactory, the hook was discarded, and the compass attached by thumb-screws at both ends.

Method of Observing.—The method adopted for the determination of the magnetic meridian is given in Appendix C of the Manual of Instructions for the Survey of Dominion Lands. The observer is instructed to proceed as follows and to note the following remarks:—

1. Place the instrument on a section line and after adjustment set the vernier to read the astronomical bearing of the line.

2. Release the lower clamp, direct the telescope on the line and fasten the lower clamp.

3. Release the vernier clamp and turn the vernier plate until the north end of the magnetic needle, observed with a magnifying glass, is seen exactly opposite the zero mark. Tap the trough lightly with the pencil or hit the milled parts of the foot-screws with the finger nail to be sure that the needle has taken the position of rest. Note the reading of the horizontal circle. Take several readings by repeating the operation.

4. Repeat operation No. 3 for the south end of the needle.

5. Enter in the notes the place of observation, date, hour of the day, weather and other remarks, if any. It is important to record auroras occurring within 24 hours of the time of observation.

The observations should be taken only when the needle is nearly stationary, say, in the afternoon after 5 p.m. if possible.

In taking the needle out of the trough, whether to rebalance it or to clean the agate, care should be taken to see that it is put back in its proper position. If replaced in the reverse position the index correction would be altered. For this reason, to safeguard against error, the position of the compass, whether "compass west" or "compass east," should be entered in the remarks after each observation when observing.

The returns should also state whether the observations are recorded in the mean time of the place or standard time.

The direction of the magnetic needle is subject to a daily fluctuation called the diurnal variation. During the greater part of the night the direction is not far from normal. In the early morning the north end of the needle in Canada moves towards the east, reaching its maximum deflection about 7 or 8 a.m. The motion is then reversed, the north end travelling westward and crossing the normal direction about 10 or 11 a.m. The extreme western position is reached in the afternoon, and then the needle comes back to its normal position at some time after 5 or 6 p.m. This march is subject to wide variations during magnetic storms. The magnitude of the diurnal variation is not constant. Observations at both eastern and western elongations of the needle on the same day, that is, between 7 and 8 a.m. and between 1 and 2 p.m., give the best results, and it is desirable that when convenient they may be taken then. This gives not only the best value for the declination, but also the diurnal variation, which it is very useful to know. Failing this, however, the best time to observe is after 5 p.m., when the needle is about in its normal position. It is true that the normal position is crossed generally between 10 and 11 a.m., but, the motion being very rapid and the time of crossing uncertain, the afternoon observation is preferable.

The place of observation must be at least three or four hundred yards away from wires carrying direct electric current. There must be no iron near the instrument. The observer must make sure that he has no iron or nickel on his person. If any magnetic object is not brought closer to the needle than fifteen or twenty times the distance at which an appreciable deflection is first produced, the effect on the needle is negligible in observations of this kind. Avoid transportation of the instrument on electric cars, as there are instances of the polarity of the needle being reversed in such an intense magnetic field.

If the needle is sluggish the observation cannot be accurate. The sluggishness is generally due to a dull pivot or a scratched cap. To keep both in proper condition the needle must always be lowered gently on its pivot and never be allowed to play except when actually in use.

Instrument Constant.—Through the courtesy of the Director of the Meteorological Service at Toronto, the index correction of every instrument used for observing was determined both at the beginning and at the close of the survey season, whenever possible. If a serious discrepancy was found between the two determinations, it was investigated and the observations taken with the instrument rejected unless the cause of the discrepancy could be satisfactorily explained.

Reduction of Observations.—In order to give a character of homogeneity to the declination observations, a reduction to a common epoch had to be applied to the observed data. To accomplish this a knowledge of the diurnal and secular variation is necessary. Again, as the diurnal variation is subject to extreme fluctuations, magnetic storms must be detected. The only method at our disposal for reduction was making use of the daily records of the declinometer at Agincourt, but the observatory being far away from where our observations had been taken, it was thought advisable to compare by actual experiments the fluctuations of the compass in western Canada and those at Agincourt. An observer was instructed to observe the magnetic declination at Rosthern, Sask., during the whole of November, 1910. Rosthern was chosen on account of being advantageously situated as a base station. The observations were taken from 7 a.m. to 4 p.m. at periods ranging from half an hour to one hour, care being taken to observe the needle at its two elongations. The work was carried out in a small silk tent in order to shelter the instrument from the influence of the wind and storms.

A comparison of the results of these observations with a diurnal variation observation taken at Jasmin, Sask., on July 10th, 1910, disclosed a diurnal range of the compass in July almost double of that at Rosthern in November.

Later, in the office, copies of the photographic traces of the declinometer at Agincourt were made for the days on which diurnal variation observations had been taken in the western provinces. On these copies were plotted the diurnal variation observations taken in the West so as to correspond in mean local time to the traces of the declinometer, and the points were joined by straight lines. From this investigation useful information was derived for the reduction of our magnetic declinations. According to our expectations, mostly all magnetic disturbances shown on the traces of the declinometer were recorded on the diurnal variation curve, and both occurred at practically the same instant.

In applying reductions the observations have been reduced to the mean of the month of the year in which they were taken. This was done in the following way:

A tabulation of the mean monthly declinations of each year was obtained from the magnetic observatory at Agincourt. The declination, for the corresponding date and mean local time at which the observation to be reduced was taken, was scaled from the trace of the declinometer at Agincourt. If the trace showed the declination then fairly steady, the difference between the mean declination of the month and the actual declination scaled from the trace was applied as a correction to the observation.

To reduce an observation to January of the same year, the difference between the mean declination of the month in which the observation was taken and the mean declination of January was applied to the observation reduced to the mean of the month.

In the absence of any definite knowledge of the secular variation a plus correction of three minutes per year, which agrees closely with the mean secular variation of the corresponding western portion of the United States as shown on the isogonic map of the United States Coast and Geodetic Survey, published in 1905, was adopted for the reduction of our declination observations to January 1st, 1912. From the few stations in the West which have been reoccupied this would appear to be a close approximation, and the maximum error from this general assumption cannot be large, as the period for reduction covers only three years.

Dip and Total Force.—During the season 1908 dip and total force observations were taken by Mr. J. E. Morrier, D.L.S., at Norway House, Oxford House, Fort Churchill and York Factory.

In 1910 similar observations were taken by Mr. C. Engler, D.L.S., during his trip from Athabaska Landing to Fort Smith, and subsequently by Mr. J. A. Cote at different points between Edmonton and Calgary. Unfortunately the results of these observations were lost during a fire at Carstairs, Alberta.

During the miscellaneous surveys made by Mr. P. A. Carson, D.L.S., in 1910, about 24 stations were occupied for dip and total intensity, between Swan River, Man., and Lashburn, Sask. Every complete observation consisted of a dip, a total force and a dip, the mean dip being used in working out the total force. This complete observation was generally duplicated at every station. In some instances the same station was reoccupied during the season and the results compared with those already obtained.

The instruments used for the determination of these magnetic elements were Dover dip circles, the constants of which were determined both before and after every season's work. The total force constant was the mean of at least six observations.

The following are the directions for the use of the dip circle and attachments in observing for magnetic declination, dip and total force.

The conditions to be satisfied in choosing a magnetic station are freedom from present and probable future local disturbance, combined with convenience of access. Proximity of electric railways, masses of iron or steel, gas or water pipes, buildings of stone or brick, should be avoided. A quarter of a mile from the first, 500 feet from the second, 200 feet from the third and fourth may be considered safe distances. The station should be at least 50 feet from any kind of building. If any doubt arises in the selection of a station on account of the possible existence of local disturbances, two intervisible points a hundred yards or more apart should be selected and the magnetic bearing of the line joining them observed at both. A lack of agreement between the two results is evidence of local disturbance.

When taking the observations, the instrument box, especially the bar magnets, should be 40 or 50 feet away for the declination observation and 25 or 30 feet for the dip and total force observations. All knives, etc., should be removed from the person. It should be noted also that iron is frequently present in buttons, hats, neckties, etc.

Care should be taken to keep the instrument in good adjustment, clean and free from dust. A camel hair brush, pith, chamois and tissue paper are supplied for that purpose.

The dipping needles should be carefully guarded against moisture, and after use should always be wiped dry with chamois or tissue paper. They should be put back in the box with poles of opposite polarity at the same end and should be magnetized afresh for each station.

The bar magnets should be touched with the hands as little as possible and should always be wiped with chamois or tissue paper after the observation to prevent rusting. They should not be allowed to touch each other except at their opposite poles and, when placed in the box, the ends of opposite polarity should be connected by a soft iron armature.

The instrument is levelled in the ordinary way with the plate level.

The trough compass should be attached to the upper horizontal plate by means of the two thumb-screws and the telescope to the vernier arms of the vertical circle. The observation for magnetic declination is then taken and recorded in accordance with the instruments given for magnetic declination observations with the D.L.S. pattern transit.

The magnetic meridian may also be determined by means of the dipping needle. Set the vertical circle verniers to read 90° and revolve the instrument in azimuth until the needle is bisected by the microscopes and read the horizontal circle. As the dipping needle points vertically when in the magnetic prime vertical, in this way the magnetic prime vertical is found and by applying 90° the magnetic meridian.

The magnetic meridian found in this manner is sufficiently accurate, however, only for the dip and total force observations. The former method is preferable and should always be adopted when possible.

The needles for the dip observations are carried on the lid of the instrument box. Taking out one of these needles carefully wipe with tissue paper and clean the pivots with pith and having also carefully cleaned the agate planes in the box with pith, place the needle on the brass v's with the face of the needle to the face of the instrument. (The face of the needle is that side which is lettered, the face of the instrument that side which is graduated.) Turn the instrument in azimuth until it lies in the magnetic meridian (previously determined in the declination observation) and with its face to the east, and lower the needle gently on the agate planes. It will now swing in the approximate position of the dip. When it settles it ought to be slightly raised and lowered once or twice by means of the screw, so as to ensure its being exactly in the centre of the instrument. The vernier of the vertical circle is now turned until the north, that is the lower end, is seen to be bisected by the cross hair of the microscope; the lower vernier is then read. Similarly, the upper end is bisected by the upper microscope and the upper vernier read; the needle is then slightly disturbed by the screw and the readings repeated until there are three readings for each end. The instrument is now turned 180° in azimuth so that the face of the instrument

is now west and the same number of readings taken for this position. The needle is then taken out of the glass box and reversed end for end of its axis, so that it faces the other way. The six readings are again taken as before for both ends of the needle.

The needle is then taken out of the box, and its polarity reversed in the following manner: Put the needle on the reversing block, face up and secure by the brass centre piece which is intended to protect the axis. Place the reversing block so that the north end of the needle will be on the right hand and the south end on the left. Now take the bar magnets one in each hand, the north pole of the magnet in the right hand lowermost and south pole of the magnet in the left hand, and bring the opposite poles of the two magnets down on the needle, near its centre and one on each side of the brass centre piece. Draw them slowly and steadily outwards over the needle, carrying them over its ends and lifting them some inches above the level of the needle, bring them back to the middle position again and repeat. This should be done five times. Care should be taken to have the motion as nearly parallel to the axis of the needle as possible; the ledge on each side of the reversing block is intended to act as a guide for the magnets to ensure this. The needle is then put face down in the reversing block and the operation repeated in the same way. The polarity of the needle will then be completely reversed.

The observations taken before reversal are now repeated. The mean of the observed inclinations in the eight positions is the dip.

It will be noticed that the mean resulting dip will, by the reversal of the dip circle, be free from any small error in the verticality of vertical axis and also eliminate index error of vertical circle; that the reversal of the face of the needle on the agates will eliminate the error caused by any want of perpendicularity of the axis of the needle to the needle; that the reversal of the polarity will correct for any want of balance of the two ends of the needle.

Total Force.—The total intensity may be determined with a dip circle by Lloyd's method when suitable standardization observations have been made at a station where the dip and intensity are known. This method involves first the determination of the angle of dip with a loaded needle, and second, a determination of the angle through which another needle is deflected by the loaded needle when the latter is placed at right angles to it in the place provided between the reading microscopes and protected by the brass shield. As the determination of total intensity by this method is relative, it is necessary to guard, as far as possible, against any change in the magnetism of the two needles and to use the same weight in the field as during the standardization observations. Their polarities must never be reversed, therefore, and they must not be allowed in close proximity to the bar magnets when these are being used to reverse the polarity of the regular dip needles. The needle which is weighted with the small wire is the loaded needle and is called the statical needle; the other is called the dipping needle. Neither of these needles must ever be touched with the bar magnets. Turn the instrument into the magnetic meridian with its face to the east. Revolve the vertical verniers until the tangent screw points to the north. By means of the small brass clips, attach the statical needle to the vernier plate with its face to the east and its north end next to the tangent screw and put the brass protecting shield in position over it. Place the dipping needle in the usual way on the agate planes, now, moving the vernier arms, read the inclination of the swinging needle as before, both north and south ends, then reverse the vertical vernier plate so that the tangent screw is south of the centre and read the inclination again. It should be noted here that the vertical circle is graduated into quadrants, from 0 to 90 degrees, and that these inclinations should always be read from the north zero, so that if in the former part of the observation, the north end of the dipping needle should be deflected by the statical needle past the vertical line, the reading to be entered is 180 degrees less the actual vernier reading, and, if in the latter part of the observation, the north end of the dipping needle be deflected above the horizontal, the vernier must be entered with a minus sign. The algebraic difference of the two readings is twice the deflection.

Frequency and Time of Observations.—The observations should be taken at least twice at each station whenever possible. Should the two observations not agree within 5 or 6 minutes a third observation should be taken. The most desirable time of day to observe is about the time of eastern and western extremes of declination, say, at 8 a.m. and 1 p.m., and it is suggested that when convenient these times be adopted.

Suitable forms for the observations are provided. The constant "A" used in the form is a constant for the two total force needles. That and the index correction to the compass have to be determined at the magnetic observatory at Agincourt.

Coal is produced commercially in only three of the numerous coal fields of British Columbia—namely, on Vancouver Island, in Nicola, and in the neighboring Similkameen district, and in the Crow's Nest section of southeast Kootenay. Production was adversely affected in 1913 by a strike of miners and other employees in Vancouver Island coal mines, so that the output of those mines was less by 596,000 long tons than in 1912. However, there was an increase at the other fields, so that the net gross production of coal—that is, of the quantity including coal made into coke—was about 450,000 tons less than the total for the previous year, the respective totals having been, for 1913, 2,576,071 tons of 2,240 lbs., and for 1912, 3,025,709 tons. The quantity of coal made into coke was 440,091 tons in 1913, as compared with 396,905 in 1912. The net production of coal disposed of as such was, in 1913, 2,125,980 tons, and in 1912 2,628,804. A summary of the production of coal in the several districts follows:

	Tons of 2,240 lbs.
Vancouver Island mines	962,620
Nicola and Similkameen mines	202,708
Southeast Kootenay	1,350,683
Total production (gross)	2,576,671

According to Consul Felix S. S. Johnson, Kingston, Ont. (United States Consular Report), the success of experimental work conducted by the Canadian Government in the manufacture of peat, has resulted in the fact that there are now two private concerns producing peat, one at Alfred, Ontario, and the other at Farnham, Quebec. The product is said to be satisfactory for use in grates and for cooking purposes. In connection with the new industry the Canadian Government will experiment with the production of gas and electrical energy from peat. At the fuel testing plant in Toronto a 60 horsepower gas producer engine is operated on gas from peat. If these experiments are successful, sections of the central peat-producing districts of Canada where water power is not available will be able to obtain power from a series of these gas-producer engines.

PAVEMENT WORK IN ST. JOHN, N.B.

DETAILS OF SPECIAL DESIGN AND CONSTRUCTION—ADAPTED RAIL SECTIONS, TRACK BASINS, ETC.—NOTES ON EQUIPMENT AND METHODS EMPLOYED.

THE following is a general description of pavements laid and paving methods employed in the City of St. John, N.B., during 1913.

At the outset of the season the Public Works Department had mapped out a programme of about 30,000 sq. yds. of pavement to be laid under the Local Improvement Act. When the time had arrived to call for tenders, however, the yardage was reduced to about 5,000 yds. This is accounted for by the fact that the owners of one-third of the total abutting frontage had the necessary power to petition and stop the laying of any pavement under the Act which provided that the abutters should pay one-half and the city the other half of the total cost of the pavement. It may here be stated that the present Commissioner of Public Works has had framed a new Act in which it is provided that sixty per cent. of the abutting frontage shall be necessary to stop the laying of any pavement. Even this Act does not give the city the necessary authority to force a single yard of pavement where it might be absolutely needed.

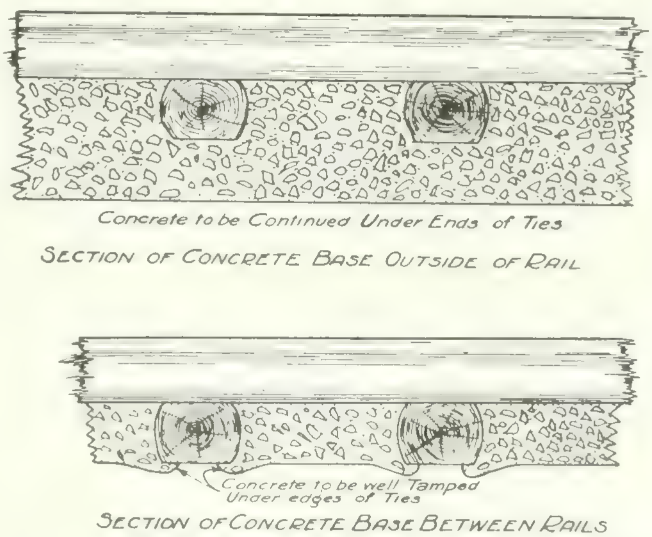

Fig. 1.—Sections of Concrete Base Adjacent to Rails.

With the small yardage above noted as being left it was decided that it would be useless to call for bids on sheet asphalt as recommended for these streets. So, a split was made and tenders asked for the concrete base, brick and granite track sections, there being local contractors in this line of work. It was decided the asphalt surface could be laid by city forces by day labor.

Contracts were accordingly let for concrete and setts. Shortly afterwards some other streets asked for pavements, which brought the quantity up to approximately 12,000 yds. As these streets were all suitable for a smooth pavement, a 2-inch bitulithic surface was contracted for, and in one case both surface and base was laid by the contractors for this material.

The general design of pavement laid during the past year is about the same as that adopted in most places where bitulithic pavement has been laid. It will, therefore, not be necessary to elaborate upon the design with the exception of the few following points. In the specifications, Mr. G. N. Hatfield, the City Road Engineer, has defined the results to be obtained leaving as far as possible to the contractor the methods to be employed. At the present time there is no local contractor equipped with any modern street paving machinery except a concrete mixer. The only road rollers available are the property of the city, which are necessarily hired out to enable the local contractors to bid upon the work.

Perhaps the only real departure from the general line of construction has been performed in the track section of some of the streets paved. To this work the accompanying illustrations chiefly allude. The concrete, as shown in Fig. 1, is not carried continuously under the ties between the rails, the specifications calling for the ties to be thoroughly tamped with concrete. But from

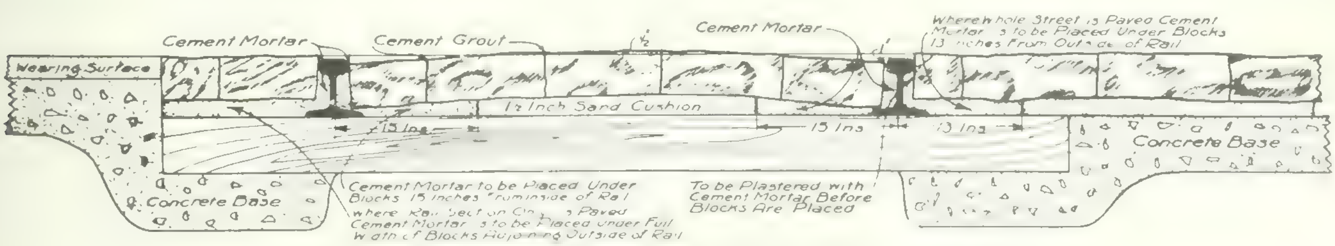

Fig. 2.—Detail of Rail Section for Granite Block Pavement.

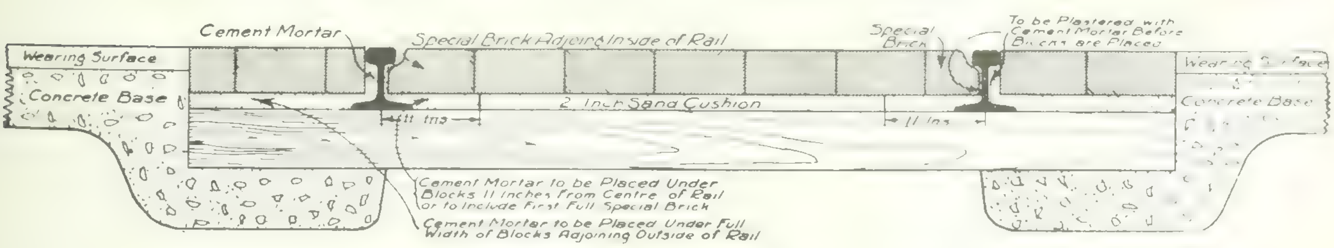

Fig. 3.—Detail of Rail Section for Vitrified Brick or Scoria Block Pavements.

the centre of rail to the outside end of ties the concrete is so placed that it is continuous under this section. In the opinion of the City Road Engineer the extra work and material is unnecessary between the rails if the ties are well supported under the rails and outside ends. Experience in railroading has shown that if all ties are well

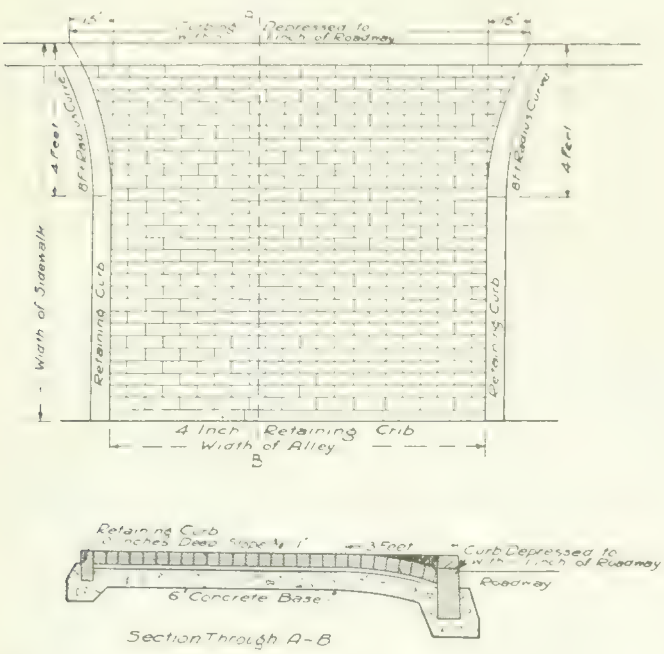

Fig. 4.—Plan and Section of Type of Paved Alley and Street Intersection Used in St. John, N.B.

tamped on the outside end and under the rails, it is inadvisable that they be extensively tamped between the rails. It has been noted on numerous occasions that railroad ties have snapped in the centre because too much attention had been given to the tamping of the section between rails. Moreover, it has been found that calling for continuous concrete under the ties has added twenty-five to thirty cents per sq. yd. to granite pavement. Again, it proves a continuous round of trouble to the inspector trying to compel the contractor to fulfil this part of the specifications. On the latter's behalf it may be stated that it certainly is slow and irksome work to dig under the ties laid in old macadam.

For a wearing surface between car rails and eighteen inches outside granite block has generally been adopted, but during the last two seasons vitrified brick has been laid on two streets. In all cases up to 1913 the blocks and bricks were paved flush with the top of rails, leaving a rectangular groove for the flange of car wheels. In both cases this method has proved rather unsatisfactory as the cement grout which was filled up to the ball of the rail has become badly rutted in places, and the vitrified bricks were soon badly spalled or broken, being unable to stand the blows of traffic in this exposed condition.

To overcome the difficulty where granite blocks were used the groove was formed as narrow as possible, which was found to be 1¼ in. This method is evidently an improvement, but from all indications will not prove entirely satisfactory. During last season's work in laying granite block the rectangular groove was abolished, and the blocks set in under the ball of the rail and crowned up at the centre to ½ in. above the top of rail, as shown in Fig. 2. The camber was made as acute as possible adjoining the rails, so that on the flat grades the track section would not have the appearance of being entirely flooded during wet weather. The water would be confined to a comparatively narrow section adjoining the rails. Where bricks have been employed specially grooved scoria blocks have been used adjoining the rails, as shown in Fig. 3. To date both of these methods have proven very satisfactory.

The above difficulty could otherwise be overcome by requiring the tramway companies to supply the necessary groove by using a heavily grooved rail.

As a guide to the contractors in excavating and laying pavements several methods have been employed, such as a template. This is used where track is placed in the centre of a roadway which was first graded and used as a datum for the template, the other end being supported and moved along the top of the curbing. Where the cross-section of the street was so irregular that a single template could not be used iron pins were placed in the section every twenty feet and in streets with no rails the ordinates were computed from a cord tightly stretched from curb to curb. By this method the finished work could be readily checked and errors, if any, placed where they belong. In the same way the template proved an undisputed judge.

For pavements laid by the city forces a template was designed which meets any case to which the formula for an eccentric crown is applicable. This is shown in Fig. 5. The section formed by this template is two straight slopes joined with a short vertical curve which might be much shorter. Such a section will tend to distribute traffic as the very centre will be the least pleasant to

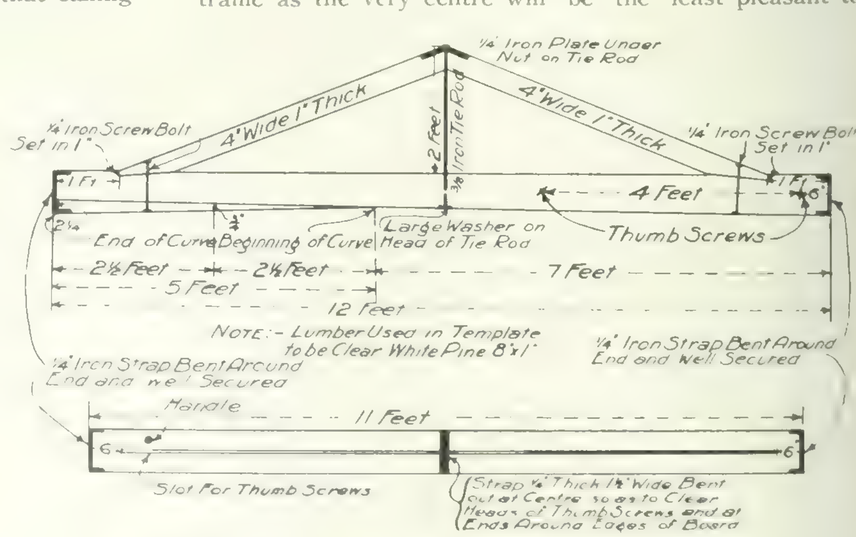

Fig. 5.—Details of Template Used by City of St. John, N.B., in Pavement Laying.

horses. On this template there is attached a small level which is set to a crown of one-fiftieth of the total width of the roadway, and also graduated to different crowns as far as possible. No doubt a metal frame could be

employed to hold the bubble with an adjustable thumb screw for changing the height of crown. By means of this template the foreman can crown the street by working from the opposite curbs or gutters, and if either of these does not properly exist all that he requires are a few pegs along the centre line of crown. The template

was changed, as noted above, it presented no handicap to the successful use of the basin.

From a study of the diagrammatical illustrations, it may appear to some that there is a greater surface of cover than conditions, considered with respect to expense, warrant. It is quite desirable, nevertheless, to

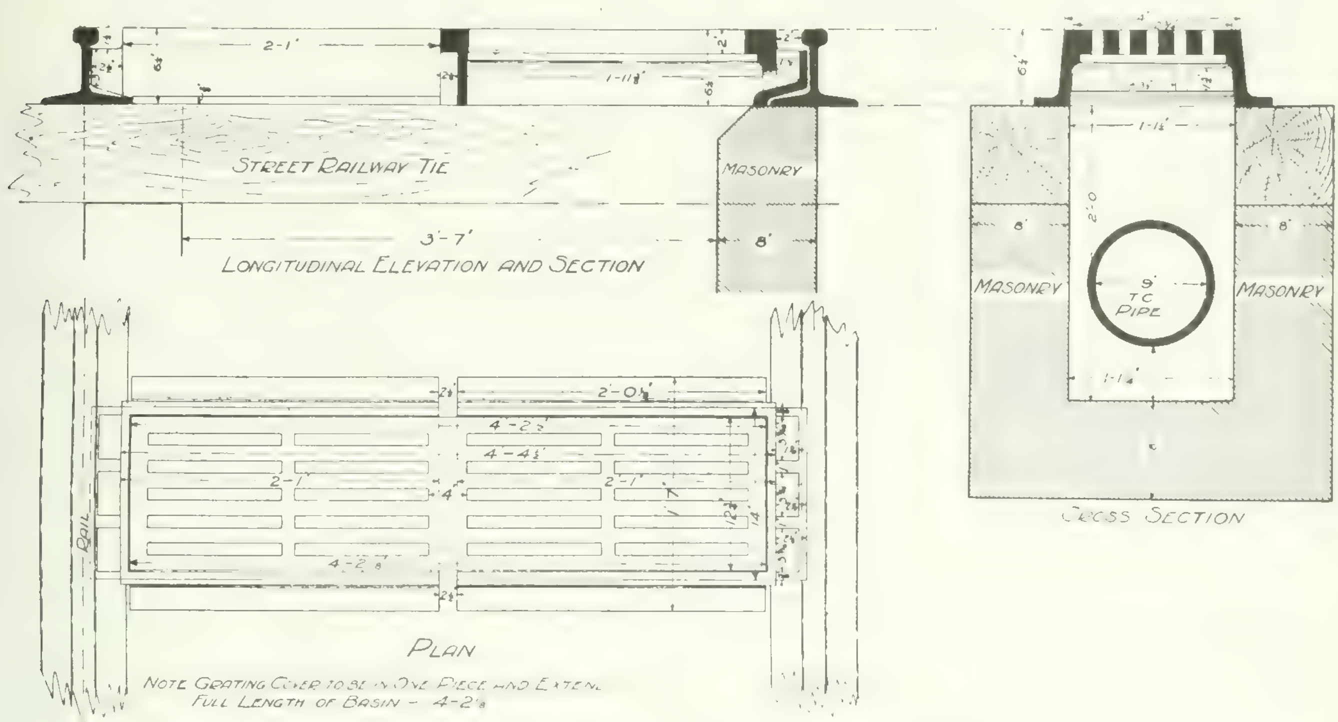

Fig. 6.—Plan and Sections of Track Basin, St. John, N.B.

is designed to meet the conditions of a medium crown, and when changed to suit others it is not absolutely correct from a theoretical standpoint. No appreciable error is involved, however, when so used in practice.

Fig. 6 illustrates a form of track basin designed last season. Several basins of this pattern have been placed

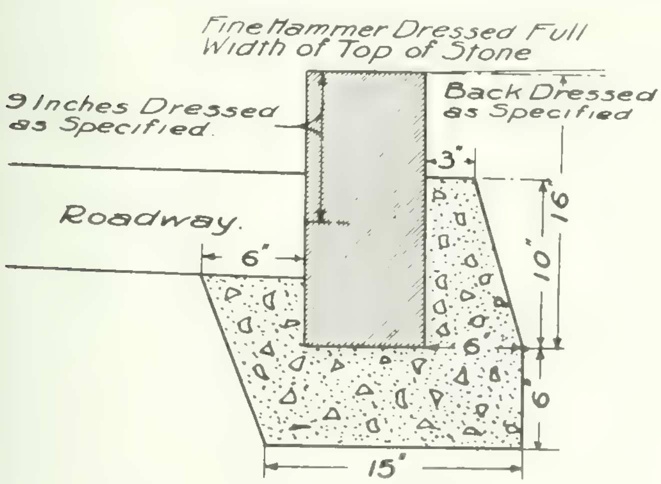

Fig. 7.—Details of Curb Setting.

and are proving very satisfactory. With little attention necessary, they take care of all water which runs along the groove provided for the car wheel flanges, as shown in Figs. 2 and 3. Although the style of track section

have a comparatively large pit to accommodate the silt and refuse which reaches it. Provision must also be made for easy cleaning. With these points in view it was decided to specify a cover of perforated iron. It can be readily lifted, and when winter thaws occasion

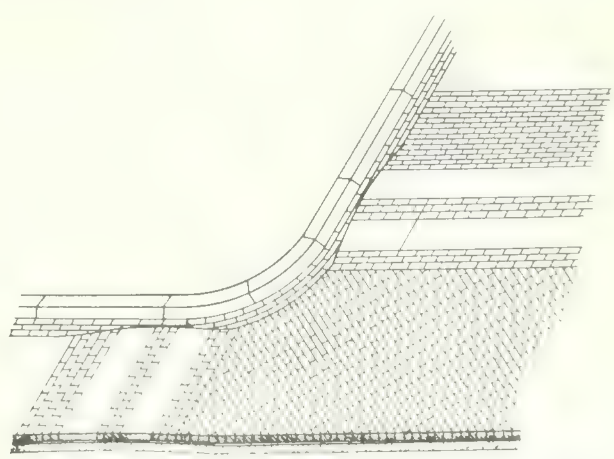

Fig. 8.—View Showing Setting of Bridge Stones at Street Corners.

excess of water with the trackway somewhat banked up with snow, these large gratings will readily take care of it.

The designs are those of Mr. G. N. Hatfield, City Road Engineer, to whom we are indebted for the above information and drawings.

THE PRESENT STATUS OF SANITARY ENGINEERING.*

By John W. Hill, C.E.,
President of the Ohio State Board of Health.

THE sanitation of cities is fast becoming an art, and the various features of sanitary work are being by degrees reduced to a science, so that certain steps can now be taken by a municipality for the collection and reduction of wastes—the collection and disposal of sewage—and for improvement of public water supply with positive assurance of success. Some difficulty has been experienced in the reduction of city wastes and disposal of sewage, partly by reason of the attempt to realize a profit on the operations and partly by the complex character of the substances to be handled. Setting aside profit and adopting the reduction processes to the materials to be destroyed or rendered innocuous, and allowing the sanitary rather than the commercial interest to prevail, satisfactory results can now in nearly every instance be expected.

Some cities, like Boston and New York, can impound water from unpolluted watersheds, in great reservoirs, at an elevation which will furnish gravity pressure for a low service supply, and this water will be purveyed in its natural condition, while other cities like Cleveland, Cincinnati, Chicago and St. Louis are compelled to draw from nearby polluted sources.

Gravity water supplies are not always pure and wholesome, and pumping sources of great capacity are not always impure and unwholesome, although the exceptions to the latter proposition are rare. The water supplies of Cincinnati, Philadelphia and Hamburg are obtained from seriously polluted sources, but by filtration the water is made safe for domestic use.

The Ohio River at Cincinnati, the Schuylkill and Delaware Rivers at Philadelphia and the Elbe River at Hamburg are badly sewage polluted streams at the intakes of these several waterworks. But by resorting to methods of purification which long time and broad experience have shown to be reliable, these polluted waters have been rendered as safe as the water flowing at the headwaters of these streams.

Surface water from unprotected watersheds is seldom safe to drink without boiling or filtration, and as the water supply of a whole city cannot conveniently or cheaply be boiled before use, filtration is the only recognized method by which purification and clarification can be accomplished. The use of slaked lime and iron, as at St. Louis, or of hypochlorite of soda or bleaching powder, as at Cleveland, cannot at this time lay claim to be considered as substitutes for filtration, although both are at times and under some conditions useful and valuable adjuncts of filtration. Free chlorine as applied at the Cincinnati filtration works, or chlorine gas as used at Wilmington and Delaware, and ozone as used at St. Petersburg, Russia, and on a small scale in some of the waterworks of Holland, are safeguards to doubtfully filtered waters, and are to be commended as aids to the broader and older methods of water purification.

The removal of all, or even of the pathogenic forms of bacteria from a polluted water by ozone or chlorine or by an electric current does not satisfy the requirements of modern sanitation. People will not drink dirty water, even if is certified as pure and safe, and filtration is the only recognized method capable of broad application, which will render a turbid water clear, safe and attractive. Filters of the slow sand or of the rapid type are capable when skilfully managed, of converting a polluted water into a safe drinking water, but the skilful management is not always forthcoming, so that some additional treatment to supplement filtration has come to be considered as desirable in some instances, and necessary in others, to render public water supplies absolutely safe.

The purification of a previously polluted water supply, however, does not solve the whole problem of the safety of the water as regards typhoid fever at least, nor perhaps as regards some other diseases known to be water borne. Pure water cannot be distributed through foul mains and remain pure, and some thought must be given to the influence of old water pipes containing deposits from polluted water which has flowed through them for years before the water supply was filtered or before pure water from a natural source was substituted.

The writer and others who have had to operate large city filtration works have sought information and have speculated on this point, and in the case of the filters for West Philadelphia, the typhoid statistics of that district of the city, seemed to show that ninety days after the distribution system began to receive the filtered Schuylkill water, all external evidence indicated that the old deposits were washed out of the pipes or that all noxious matters had been removed from them. Similar experience at various places, including London and Hamburg, have been received from abroad. But later experience elsewhere than Philadelphia, convinces me that complete safety from typhoid fever from a water source requires that the old deposits from a polluted water supply should be wholly and certainly removed from the mains, before they can be regarded as safe carriers of a purified or pure water. Recent experience seems to show that even seven years is not enough to eliminate the danger which may arise upon sending pure water through previously foul distribution pipes.

Water mains can be cleaned and deposits removed by several mechanical methods which have stood the test of time, and where the quality of a public water supply is about to be improved this cleaning of the mains should go hand in hand with filtration or other improvement in in the quality of the water. What boots it to advance the standard of water to a high degree and then destroy its sanitary quality by sending it to the consumer through dirty pipes? Experience has come to me in a very serious way, both in filtering the water supply of Philadelphia and otherwise, which convinces me that some of the typhoid fever vagaries from a filtered water are not chargeable in some instances to poor operation of the filters, but rather to the stirring up of old deposits in the mains which contain the necessary matter for the development of the typhoid organism in the human system. A considerable increase in the rate of flow through water mains will start these old deposits and destroy the wholesomeness of a well filtered water. The evidence of the change is manifested to the consumer by the turbidity of the previously clear water and very unfortunately sometimes by typhoid fever in his family.

The prompt removal of sewage from premises is necessary to health but in effecting this removal we should have some regard for the health of others who may become victims of our carelessness or indifference. Aside from the desire to keep our streams free from pollution they should not be used to carry sewage pollution from

*Extracts from address read before Conference of State Board of Health with Municipal Health Officials January 22-23, 1914.

one town to the water supply of another, and some remedy must be sought to guard against this evil.

It might not be out of place to here remark that some twenty years ago I entertained the thought that if all water supplies for domestic and dairy use, and any other use in connection with food or drink, were free from typhoid fever organisms that typhoid fever would soon be stricken from the list of diseases, and that water in some form or condition was responsible for our continued typhoid rates, and that with pure or purified water, universally used for dietetic purposes and in connection with articles of diet ingested even uncooked, we might hope for practically the elimination of typhoid.

It may be recalled that Prof. Dr. Von Pettenkofer leaned strongly to this theory, based largely no doubt upon his experience with the disease in Munich, after the introduction of a new public water supply from springs in the Mangfall Valley.

Various methods of sewage disposal have been tried and some permanently adopted.

Screening the coarser floating particles from sewage is a part of every system of disposal. Grit chambers to remove by limited sedimentation the heavier solids held in mechanical suspension is also a part of every system, where combined sewers are in use. But after these two steps have been taken, the further treatment takes a wide range from simple and limited sedimentation, to the most refined methods of filtration adapted to the treatment of sewage.

The treatment of sewage will depend upon the disposition of the final effluent. If the effluent is to be discharged into a rapid flowing stream of large relative volume, the degree of purification need not be so high as it should be when the dilution and opportunity for oxidation of the decomposable matters in the sewage will be less. If the sewage outfall is into a stream not drawn upon for public water supply, nor used for watering stock, and where nuisance only is to be considered, the purification need be only sufficient to avoid putrescibility. But if the stream is used below the point of sewage outfall for public water supply, or for watering stock, and the effluent must be no worse, and possibly better than the water naturally flowing in such stream, then the most advanced and comprehensive methods of purification will be necessary to meet the present sanitary requirements.

In the case of a public water supply, the standards of quality whether the water be naturally wholesome, or made so by filtration, will be about the same everywhere, so that the analytical conditions which determine wholesome water are not difficult to establish, and will not vary materially the world over. But standards for sewage effluents are not so easily established. Thus sewage discharged into New York harbor where the fresh and salt water dilution will be very large and the water nowhere used for domestic purposes, nor for the watering of stock, may be much inferior to the sewage effluent which can safely be discharged into Lake Erie at Cleveland, or of the sewage effluent which can safely be discharged into the Ohio River at Pittsburgh.

Each place may require a standard of sewage effluent different from the other places, and as a consequence the systems of sewage purification will take a wide range of design and efficiency, depending upon the place and condition of final discharge.

In Europe almost every known method of sewage disposal has been tried. Some of these methods have survived the experimental stage and have become standards under proper conditions, others have been tried and finally abandoned. At Glasgow, for example, the sewage is simply screened, the grit intercepted, a few hours of continuous sedimentation allowed, when the effluent is run into the Clyde, on the ebbtide, and the sludge pumped from the sedimentation tanks and carried out to deep water in the sea, in sludge boats constructed for the purpose. Some of the heavier sludge, however, is loaded on railway trains and then used for filling lowlands along the river below Glasgow, and some of it is pressed in order to extract part of the water, and is then dried and sold as a fertilizer. The fertilizing value of the average sewage sludge is low, and the thought once entertained by Victor Hugo and others of less romantic mind, that the elements of a complete fertilizer were to be found in domestic sewage has long since been disproved. Sewage has been successfully applied to certain kinds of crops, but it has no broad application as a general fertilizer, and when so used the crop must be adapted to the sewage. Of course, something else must be grown on the land besides "alfalfa" and "cabbage" if we are to live, and to the great crops of corn and wheat upon which the farming life of the nation depends, it is doubtful if a raw sewage can be of material benefit.

The disposal of sewage should be conducted upon strictly sanitary lines, and if processes can be worked out which will enable some portion of the sewage to yield a profit, these must have in view the sanitary end as the first object.

In this state the proper treatment and disposal of sewage is generally required to prevent pollution of our streams, and to avoid nuisance. Some of our streams, like the Cuyahoga River at Cleveland, and Millcreek in and north of Cincinnati, are now so vile from untreated sewage effluents that at times it seems that it only requires a match to set fire to them. But these conditions will soon be remedied in both places, and we may expect to see the waters of these streams flow into Lake Erie and the Ohio River respectively, as clear and sanitary as the natural waters of the Lake and River, and perhaps safer for ordinary uses.

It is a theory in one part of Germany to-day, that after the sludge has been precipitated by a few hours' sedimentation from raw sewage, that the effluent can be safely discharged into a relatively small stream, provided the stream has a good current, and no places occur in it where the unsedimented solids in the sewage can strand. That is to say, the sewage must be kept moving until it reaches a body of water large enough to furnish proper dilution. The dilution in the small streams may be low provided the current is maintained, and to this end brooks have been improved and artificial channels created, for the carriage of the sewage effluents at constant safe velocities.

The Imhoff septic tank has come into vogue in the Emscher district of Westphalia, as an adjunct of this system. In this district all the smaller streams and constructed channels flow into the Emscher River, and the river finally empties into the Rhine, where the volume of flow is relatively large.

If we pursued our plans for sewage disposal as persistently and cheerfully as do our neighbors in Europe, much better results would probably be accomplished, and less complaint would be heard from those to whom the sewage effluent of our cities is a nuisance and sometimes a menace to the public health.

The collection and proper disposal of garbage and other city wastes is another branch of sanitation that

must not be neglected. Because we cannot readily trace disease to city dumps, there is no reason why these eyesores should remain as blots on the landscape. All these dumps are more or less a nuisance, and in decency should be abated. It may cost something to collect and properly dispose of wastes and rubbish, but very little that is desirable is obtained without cost, and no expense that we indulge in will yield so large a return in the beautifying of our small streams in the unimproved outskirts of our cities as the complete abolition of our waste and rubbish dumps. No one wants a garbage or waste dump on or near his premises, but he is not so particular about someone else's premises, and that which is unsightly and an offence to his finer sensibilities will likely be a nuisance and offence to others who from locality are compelled to endure it.

In cities of less than 100,000 population it is thought that garbage and other wastes and rubbish are best disposed of by combustion in high temperature destructor furnaces, if sanitation is the object in view.

In large cities, however, the garbage can be separately collected and reduced to inoffensive and saleable products with reasonable profit and the other wastes and rubbish from domestic, commercial and municipal sources can be collected, sorted and some material of value obtained from them before the useless matters are destroyed. The picking over of garbage wastes and rubbish to obtain revenue is a doubtful procedure. Great risk is run by the "pickers" in handling cast-off clothing, bed linen and some other household articles. The picking of inorganic matter may be attended with no great risk, but all material which by chance can transmit disease should not be picked and preserved, but be promptly put through the combustion furnace and rendered harmless.

In some cities the garbage is collected and delivered to the reduction works at cost, the reduction being performed under contract by private parties, while in others the reduction as well as collection is conducted by the municipality. The net profit from the handling of the garbage in Cleveland, for the year 1909, was $85,715, and by the adoption of the same energetic and efficient methods in some of our other cities corresponding results can be expected.

Garbage when reduced will yield grease and fertilizer, but the value of the fertilizer will be low. The grease is a valuable product and this together with the articles of value "picked" from the garbage constitute the source of profit.

Small cities cannot successfully conduct garbage reduction works owing to the lack of sufficient raw materials to work upon from day to day, and in these, with sanitation as the object, the garbage and all other wastes and rubbish should be reduced to clinker, ash and gases, in high temperature "destructor" furnaces. "Picking" the garbage and wastes may furnish some material that is saleable but after this has been done, the remainder of the material should be quickly destroyed.

In suburbs of cities and in villages the rubbish and wastes from the household can often be destroyed on the premises, and when this is done the burden on the municipality will be correspondingly lessened. Organic wastes and rubbish of whatever kind should not be alowed to accumulate, and the same desire for cleanliness of person and clothing which we are all supposed to have should apply to the household, the factory and the store.

How often are we shocked at sight of dump heaps and rubbish piles along our trunk line railways in the outskirts of cities; useless in themselves, eyesores, nuisances and sometimes the cause of ill health?

The City of Cincinnati collects and reduces its garbage, but ashes, street sweepings, domestic, commercial and building wastes and rubbish are collected as daily tributes to our waste heaps or so-called "city dumps." Things that cannot be used should be destroyed, and not left to encumber the premises or the landscape, to offend good taste and obscure the face of nature.

No one should be offended by an order to clean up his premises and keep it clean, to collect and reduce, pick over or destroy what he cannot use, with the best means at his disposal, and when the individual has done all that can reasonably be expected of him then the municipality must do the rest.

PERMEABILITY OF CONCRETE.

Results of great importance to contractors, engineers and farmers who have to do with concrete construction are being obtained in a series of tests to determine the rate and the amount of flow of water through concrete. The College of Engineering of the University of Wisconsin is making these tests with the object of finding a simpler means of making concrete watertight. A large cement company in the middle west is co-operating with the college by offering the facilities of its plant.

Already some interesting results have been gotten in the effect of the length of time of mixing in a machine mixer of the batch type; the effect of the percentage of mixing upon the imperviousness of the concrete; the effect of having sand in dry condition before mixing; and the effect of having the sand wet.

The experimenters have found that good results are obtained if the concrete remains in the mixer from two to three minutes when dry materials are employed. For cases where the sand and gravel or stone are damp a considerably longer time is required. Therefore the use of wet sand should be avoided if possible. The experiments showed that mixtures consisting of 1 part of cement, 1½ parts of Janesville sand of the Torpedo grade, and 3 parts of Janesville gravel, when mixed to a wet consistency, are impervious to water when subjected to a pressure of 40 pounds per square inch. Mixtures as lean as 1 part of cement to 6 parts of gravel (a graded mixture) have been made impervious at high pressures by using care in proportioning the amount of water and in mixing the batch. The specimens used in making these tests are cylindrical in form and so made that the faces of the cylinders, which are 13½ inches in diameter, are exposed to the predetermined water pressure. The thickness of the concrete through which the water must pass can be varied from 4 to 18 inches. Ample provision is made for cleaning both faces of the cylinder before placing it upon the testing apparatus. The apparatus itself is so arranged that very accurate tests can be made.

The importance of these experiments will be more sufficiently appreciated when it is understood that a large proportion of the trouble arising from poor concrete is due to the use of defective sand or gravel.

The department is also studying the effect of varying the percentages of cement and water, the gradation of the sand and gravel (by this is meant the size of the rocks and the fineness of the sand), the proportioning of the mixture, the thoroughness of mixing, and the effects of different conditions on the hardening of the specimens.

LOSS OF HEAD DUE TO BENDS IN WATER PIPES.

THERE has been much argument as to the loss of head due to bends or curves in pipe lines. Many theories have been advanced and many attempts to determine the laws which govern it have been made, but after great care, different experimenters have arrived at quite different conclusions. The result is an abundance of experimental data on the subject with small means of determining what are most feasible and most reliable.

A good deal of accurate information, derived from the data already at hand, is contained in a paper on the subject by Mr. W. E. Fuller, read by him before the New England Waterworks Association last September. It is in such a form as to admit of ready determination of the probable loss of head in bends and curves under the conditions that are ordinarily met with in waterworks practice.

It is known that water passing around curves and bends loses a greater amount of head than when passing through an equal length of straight pipe. When the direction of the flow of water is changed, the distribution of velocity and pressures in the pipe is also changed, eddies are set up, and probably other actions take place which cause this excess loss.

It is more convenient, in comparing different bends, to divide the total loss of head due to the bend into two parts: (1) that which occurs in an equal length of straight pipe; (2) the excess loss due to the curve. If this is done it is necessary to assume that the effect of roughness of pipe, condition of joints, and other matters which affect the flow in straight pipe have the same effect on the flow in curved pipes. Quite probably this is not exactly true, in which case bends of the same dimensions with different hydraulic conditions would give different excess losses of head. The experimental data are insufficient to decide this matter, but they indicate that the effect of roughness, etc., is not greatly different in the two cases. Loss of head due to bends will be considered as that portion of the total loss in excess of the loss which would occur in an equal length of straight pipe.

It is known that the disturbance caused by the bend is continued for some distance in the straight pipe beyond the bend and that the loss due to the bend continues in this straight pipe. It is also probable that the pipe preceding the bend, causing more or less eddies, according to its condition, may affect the loss due to the bend. The fact that some of the loss due to the bend takes place in the straight pipe makes it necessary in experimental work to measure the head at some distance beyond the bend itself. The loss due to pipe friction must then be eliminated before the loss due to the bend can be obtained. This pipe friction represents a large proportion of the total loss, so that errors in obtaining it materially affect the loss due to the curve. With all these difficulties to overcome it is not surprising that the different experiments should not agree closely.

Main Points at Issue.—For practical purposes it is essential to know the effect of both the radius of the bend and the velocity upon the loss of head for pipes of different sizes.

Until recent years Weisbach's formula, based upon experiments made on small pipes, was generally accepted. This formula is:

h_b (additional loss of head due to 90° bend) = 0.13

$$+ 1.85 \frac{D}{2r} \cdot \frac{v^2}{2g},$$

in which D is diameter of pipe, r the radius of the centre line of the bend, and v the average velocity in the pipe. On this basis the greatest loss of head would be from a bend of the smallest radius, and the longer the radius the less the loss would be.

Experiments made at Detroit on pipes of 12, 16, and 30 in. in diameter, indicated losses quite different from those given by the Weisbach formula. From these experiments it was concluded that the loss of head was a minimum for bends with radii of about two and one-half times the diameter of the pipe. These experiments also indicated that the loss did not in all cases vary as the square of the velocity.

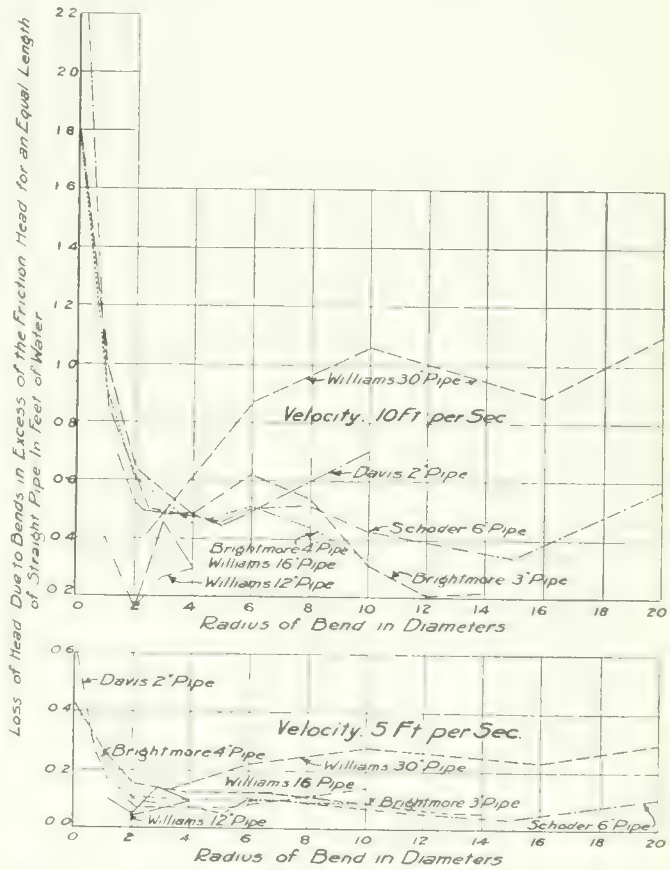

Fig. 1.—Loss of Head Due to 90° Bends. Radius in Diameters.

Further experiments made on 2, 3, 4 and 6-in. pipe showed that the Weisbach formula did not hold for larger pipes under ordinary conditions of service. These later experiments, however, did not confirm the Detroit experiments as to the minimum loss occurring with bends of a radius of 2½ pipe diameters. These different experiments indicated quite different variations of loss in relation to the velocity. Some of the experiments showed this relation as high as $v^{2.75}$, while others showed it as low as $v^{1.5}$.

These experiments give the best basis that we have of obtaining the loss of head in bends.

The experiments were all carefully made, every effort being made to eliminate errors. The conditions existing for the different experiments were nea enough alike to justify the expectation of at least an approximate agreement.

In the discussion of the question resulting from these experiments it seems to have been assumed that the loss of head in bends on different sizes of pipe should be the same when the radius of the bend in terms of the di-

ameter of the pipe were alike. The writer sees no valid reason why this should be so. With so many different factors contributing to the loss there seems no reason to assume such a relation. If this assumption is abandoned, a much closer agreement between the data can be obtained and it seems better to accept the experiments as they stand, adjusting the conclusions to the data rather than to assume that some of the data are in error simply because they do not satisfy the above assumption.

Effect of the Radius.—A study of the data shows that the loss is more nearly the same for different sizes of pipes with bends of the same actual radius in feet than for bends of the same radius in pipe diameters. This is shown by a comparison of Figs. 1 and 2.

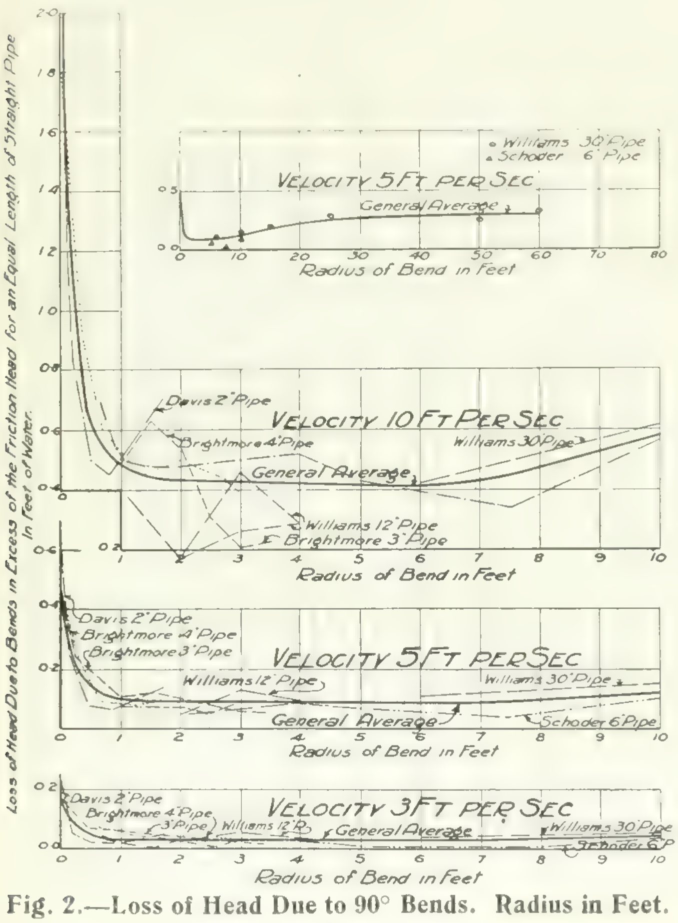

Fig. 2.—Loss of Head Due to 90° Bends. Radius in Feet.

Fig. 1 shows a plotting of the data on the basis of the radius in pipe diameters, while Fig. 2 shows a similar plotting on the basis of the radius in feet. On Fig. 1, while the curves representing the losses in bends of diameters from 2 in. to 6 in. agree fairly closely, those for the larger pipes are very different. On Fig. 2 a much closer agreement between the small and large pipe curves is obtained.

It is probable that neither of these diagrams is on the correct basis, and that the actual relation between the loss of head and the radius is a more involved one. Possibly the inner radius or the outer radius of the bend should be used for the comparison instead of the radius of the centre line; or it may be that both r and D are involved in some more complicated form.

On Fig. 2 the average curves drawn fit the data approximately and may be used for obtaining the probable loss of head in bends.

Relation of Loss of Head to Velocity.—Values of the loss of head for different velocities due to bends of the same radius, taken from the average curves on Fig. 2, were plotted on logarithmic paper in relation to velocity. From these plottings the relation was established that the loss of head is proportional to $v^{2.25}$. On this that the loss of head is proportional to $v^{2.25}$. On this basis a formula for loss of head may be stated as $h_b = kv^{2.25}$, in which k is a coefficient different for bends of different radii, and h_b is the loss of head in excess of the loss in a straight pipe of a length equal to the length of the curve. On Fig. 3 is given the values of k for bends of radii up to 60 ft. This relation between h_b and v is an average relation, as indicated by the experiments used. Further experiments may change it materially.

Practical Use of the Data.—Fig. 2 gives the loss of head due to 90 degree bends in excess of the loss due to friction in straight pipe of a length equal to the length of the curve. To compare the total loss of head which would actually occur in pipe lines containing these curves, it is necessary to take into account the relative length of the different curves. The use of long curves makes the total length of pipe less than the use of short curves giving a corresponding smaller loss in pipe friction.

The introduction of this matter brings in a difficulty in that the friction will vary as the roughness of the pipe, so that the curve giving the least total resistance for one pipe will not do so for another pipe with different

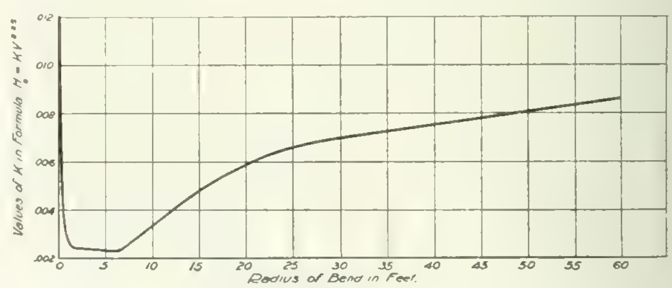

Fig. 3.—Values of "K."

hydraulic conditions. It is most convenient to compute the loss of head in pipe lines by taking the actual lengths of the tangents as straight pipe, finding the frictional resistance in it, and then adding the excess resistance due to curves and other specials.

To meet this requirement Fig. 4 has been drawn, on which is shown the excess loss of head in bends over what would occur in straight pipe of a length equal to the tangents of the curve under average conditions. The data for plotting this diagram were obtained as follows: The loss due to the curve is taken from the average curve in Fig. 2. The friction in straight pipe of a length equal to the difference between the length of the tangents and the length of the curve is then deduced. The frictional resistance in straight pipe is taken according to the Hazen-Williams formula with $c = 100$. The coefficient represents the average pipe after it has been in use for some years. As the loss of head in bends becomes of most importance at the time when the pipe is being used at its maximum capacity, which usually comes aften some years of use, this value of c will probably meet the usual requirements. For new pipe well laid this excess loss in head would be somewhat greater, while for pipe in very bad condition it would be less.

Fig. 4 shows the following interesting points:

1. The excess loss of head in bends is greater for large pipes than for small ones.

2. For large pipes a six-foot radius bend gives the least resistance, unless very long radii are used.

3. If the radius can be made very long, the least resistance will evidently be from the bend of greatest radius.

4. For small pipes, at least, with long radii the loss of head will be less than it would be in straight pipe of a length equal to the tangents of the curve. This occurs when the saving in friction head due to shorter line becomes greater than the excess loss due to the bend.

In order to show the loss of head for bends in ordinary use, Table I. has been prepared on the same basis as Fig. 4, giving the excess loss for bends made according to the New England Waterworks Association standard.

Table I.—Loss of Head Due to Ninety Degree Bends of the New England Waterworks Association Standard.

Size of pipe. Inches.	Radius bend. Feet.	Excess loss over loss in straight pipe of length equal to tangents. $v = 3$ ft.	$v = 5$ ft.	$v = 10$ ft.
4	1.33	0.021	0.073	0.37
6	1.33	0.025	0.082	0.40

30	3.0	0.026	0.083	0.41
36	4.0	0.026	0.083	0.40

Necessity for Considering Loss in Bends.—For most lines of small pipe, consideration of economy or convenience in laying will govern the selection of the bend or curve to use. Generally, of course, the use of very sharp bends should be avoided. In designing pipe systems about pumping stations, filter plants, and elsewhere, where many specials are necessary, a thorough understanding of the loss is important to avoid unnecessary loss of head.

For large pipes the losses in bends assume a far greater importance. The loss is more important for several reasons. First, the actual loss is greater for the larger pipes than for small pipes. Second, for the same velocity the frictional loss is less for large pipe than for small pipe, so that the loss in bends is a greater proportion of the total loss. Third, the amount of money involved is greater in the case of large pipe, and a greater expenditure is justified to avoid losses of head.

The importance of losses of head which occur on large pipe lines at bends and at other specials and at entrances and outlets of the pipe to structures is not as generally realized as it should be. It is not uncommon to find losses from such causes, in large and comparatively short pipe lines, a large percentage of the total loss. In many cases much greater capacity of the line could have been obtained by proper consideration of the losses in the design of these works, and in some cases the capacity could have been nearly if not quite doubled. Instances of this may be found in intake and suction pipes. The importance of these losses may be understood when it is realized that in 1,000 ft. of 72-in. pipe a single 90° bend poorly designed may readily reduce the capacity of the line by 5 per cent., and a poorly designed inlet or outlet of the pipe to a structure may reduce the capacity by fully 10 per cent. It is not uncommon to find structures on pipe lines in which the velocity is suddenly reduced to a small amount, after which it is again increased. Such structures are extremely wasteful in head. A careful design to secure gradual changes in velocity and to prevent eddies at specials is very essential in order to secure the proper capacity of large lines and to prevent the waste of capital in building larger pipe lines than are needed.

Loss of Head in Other Than 90° Bends.—There are but little data on losses in curves of radii other than 90° curves. Even with bends of small curvature the flow is disturbed, eddies are started, and considerable loss of head may result. It seems certain that the loss in 45° bends is greater than one-half that in 90° bends. Until more information is obtained, the writer suggests the use of the following values for losses of head:

For loss of head due to 45° bends, use three-fourths that due to 90° bends of the same radius.

For loss of head due to 22.5° bends, use one-half that due to 90° bends of the same radius.

For loss of head due to a Y-branch, use three-fourths that due to a tee.

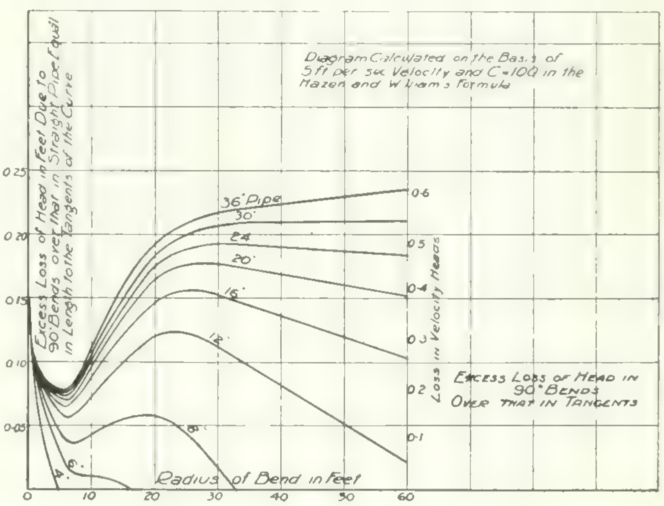

Fig. 4.

Approximate Rules for Losses of Head.—The loss of head in bends, for ordinary velocities, that is, from 3 to 6 ft., is approximately proportional to the velocity head, $\frac{v^2}{2g}$. It is convenient to express the loss in this way, and for rough approximations the following rules will serve:

For 90° bends of a radius in excess of 1.5 ft. and less than 10 ft., $h_b = \frac{1}{4}\frac{v^2}{2g}$.

For tees (bends of zero radii), $h_b = 1\frac{1}{4}\frac{v^2}{2g}$.

For sharp 90° bends of 6-in. radii, $h_b = \frac{1}{2}\frac{v^2}{2g}$.

Only further experimental work can satisfactorily settle some points involved in the loss of head in bends. Experiments which would add to the data on the loss of head in bends of large diameter would prove of the greatest service. It is for such bends that the matter is of the greater importance and the data more limited.

Messrs. Cammell, Laird and Company, of Birkenhead, England, have supplied the turbines for the Canadian Pacific steamer St. George, the installation being made at the Robins drydock at New York under the superintendence of engineers from Birkenhead.

CANADIAN PRODUCTION OF PETROLEUM AND NATURAL GAS, 1913.

THE Division of Mineral Resources and Statistics of the Department of Mines, Canada, reports that the production of crude petroleum in Canada was confined during 1913 to the old established fields in Ontario with a few barrels pumped from gas wells in New Brunswick.

The annual output has been steadily declining during the past six years and shows a further falling off in quantity produced in 1913 although owing to the higher price obtained for oil a larger total value is shown than for 1912.

A bounty of one and a half cents per Imperial gallon is paid upon the production of crude petroleum, the Bounty Act being administered and payments made by the Department of Trade and Commerce. According to the records of this Department the total output of petroleum in 1913 was 228,080 barrels or 7,982,798 gallons on which a bounty of $119,741.97 was paid. The total value of the production at the average price for the year $1.782 per barrel was $406,439.

The production in 1912 was 243,336 barrels or 8,516,762 gallons valued at $345,050 or an average value of $1.418 per barrel.

The average price per barrel at Petrolia during 1913 increased from a minimum on January 1 of $1.65 to $1.75 on April 16, $1.84 on November 6, and $1.89 on December 22.

The production in Ontario by districts as furnished by the Supervisor of petroleum bounties was in 1913 as follows, in barrels: Lambton, 155,747; Tilbury, 26,824; Bothwell, 34,349; Dutton, 4,610; Onondaga, 4,172, and Belle River, 464, or a total of 226,166 barrels. In 1912 the production by districts was: Lambton, 150,272; Tilbury, 44,727; Bothwell, 34,486; Dutton, 4,335, and Onondaga, 7,115, or a total of 240,935 barrels.

The production in New Brunswick in 1913 was 2,111 barrels as against 2,679 barrels in 1912 and 2,461 barrels in 1911.

Exports entered as crude mineral oil in 1913 were 3,650 gallons valued at $379 and refined oil 24,273 gallons valued at $3,188. There was also an export of naphtha and gasoline of 17,875 gallons valued at $4,284.

The total value of the imports of petroleum and petroleum products in 1913 was $13,339,326 as against a value of $11,978,053 in 1912. The imports have been increasing rapidly during the past few years.

Crude oil is being extensively used as a fuel on the Pacific Coast in both steamships and locomotives and the wide use of the gasoline motor has created a big demand for gasoline. The total imports of petroleum oils, crude and refined in 1913 were 222,779,293 gallons valued at $13,230,429 in addition to 1,628,837 pounds of wax and candles valued at $108,897. The oil imports included crude oil 162,062,201 gallons, valued at $5,250,835; refined and illuminating oils 19,393,627 gallons, valued at $1,386,440; gasoline 29,525,170 gallons, valued at $4,822,941; lubricating oils 6,789,451 gallons, valued at $1,172,986, and other petroleum products 5,008,844 gallons, valued at $597,227.

The total imports [illegible] were [illegible] gallons of petroleum oils, crude and refined, valued at $11,858,533, in addition to 2,144,006 pounds of paraffin wax and candles valued at $119,520. The oil imports included: Crude oil, 120,082,405 gallons, valued at $3,996,842; refined and illuminating oils, 14,748,218 gallons, valued at $1,012,735; gasoline, 40,904,598 gallons, valued at $5,347,767; lubricating oils, 6,763,800 gallons, valued at $1,077,712, and other petroleum products, 4,288,463 gallons, valued at $423,477.

There was an increased importation in 1913 of all classes of oil with the exception of gasoline, the increases being most pronounced in crude oil and refined illuminating oil.

Natural Gas.—There was comparatively little change in the production of natural gas in Ontario but a large increase in the production in New Brunswick and in Alberta. The total production in 1913 was approximately 20,345 million feet valued at $3,338,314, of which 828 million feet valued at $174,006 was from New Brunswick; 12,487 million feet valued at $2,092,400 from Ontario, and 7,030 million feet valued at $1,071,908 from Alberta.

The production in 1912 was reported as 15,287 million feet, valued at $2,362,700, and included 174 million feet from New Brunswick, valued at $36,549; 12,529 million feet from Ontario, valued at $2,036,245, and 2,584 million feet from Alberta, valued at $289,906.

These values represent as closely as can be ascertained the value received by the owners or operators of the wells for gas produced and sold or used. The values do not represent what consumers have to pay since in cases where transmission is by separately operated pipe line companies such cost is not included.

It has been finally decided by the State of New York to request the foreign relations committee of the House of Representatives to recommend that New York State be vested with power to permit the diversion of water from Niagara River for power purposes or to establish a State power plant at Niagara Falls.

The Wheeler Condenser and Engineering Company, of Carteret, N.J., have opened an office at 122 Board of Trade Building, Montreal, under the management of Jos. McKay, Jr., formerly New York manager of the company. The company make surface and jet steam condensers water-cooling towers, feed-water heaters, evaporating apparatus, etc.

One of the most interesting railway structures in the world is the bridge over the Faux Namti gorge in Indo-China, where, owing to the peculiar difficulties in the way of building a bridge of any type, it was necessary to adopt a special design suited to the only method of erection that seemed possible. The sides of the gorge are practically vertical; and there is no approach to the bridge from either side except through tunnels. The track grade is 335 feet above the river, so that no system of falsework could be used in building the bridge, while cantilevers were out of the question owing to the lack of "elbow-room." The design finally adopted consisted of two steel trusses, each hinged at the cliff side, which were erected in a vertical position and then lowered so that the ends met, forming a structure of inverted V-shape. The ends of the two trusses were firmly connected; steel towers were erected on the humps of the trusses; and, on this support, the steel deck truss, carrying the track, was placed. At the beginning of the work it was necessary to let the workmen down by ropes from the tunnel mouth to prepare the foundations of the supporting trusses. The track trusses were built in the tunnels and were then moved into position on rollers. From end to end this bridge measures 220 feet 4 inches, while the distance between the heels of the supporting trusses is 180½ feet.

SPECIAL BOARD FOR LAKE OF THE WOODS QUESTION.

One of the Privy Council committee reports approved on March 2nd by the Governor-General, deals with the organization of a Board, representative of different departments of the Government, for the special consideration of various questions that are being referred from time to time to the International Joint Commission. Questions frequently arise in which more than one department of the Government is interested and in regard to which several departments have special knowledge. In order that such questions may be fully and effectively dealt with, it has been deemed desirable that there should be some method by which advantage may be taken of the information possessed by the different departments, and thus greater co-operation secured in dealing with the problems involved.

It is interesting to note that in the United States such matters are within the jurisdiction of, and dealt with by, the War Department alone.

At the present time the question which requires the most urgent consideration is the one involved in the reference regarding the level of the Lake of the Woods, and it is suggested that a Board be organized for the special purpose of considering it, and outlining a policy for submission to the Government.

The report recommends that the working members of the Lake of the Woods Board should be representatives of the various departments affected. The Department of Marine and Fisheries and the Department of Public Works are responsible for the navigation on the lakes; the Fisheries Branch of the Department of Marine and Fisheries is interested in the propagation and care of fish and, therefore, in any change of level which may affect the spawning beds; the Department of the Interior is much interested in the water powers connected with the watershed of the Lake of the Woods, particularly those in the Province of Manitoba; the Hydro-Electric Power Commission of Ontario is interested in the water powers in the Ontario section of the watershed; and the Department of the Naval Service is charged with the work of preparing charts for navigable waters.

In view of difficulties that may be encountered in getting representatives from these various departments to act together, and in order to facilitate direct communication with the Government, it is suggested that a member of the Cabinet should be the chairman of the Board. The report accordingly recommends the constitution and appointment of such a Board under the chairmanship of the Minister of Marine and Fisheries, to consist of the following members as representing their respective departments: B. H. Fraser, assistant chief engineer, Department of Marine and Fisheries; S. J. Chapleau, district engineer, Department of Public Works; J. B. Challies, superintendent, Water Power Branch, Department of the Interior; W. J. Stewart, chief hydrographer, Department of the Naval Service and External Affairs; and H. G. Acres, hydraulic engineer, Hydro-Electric Power Commission of Ontario.

The committee also recommend that the Board be instructed to examine the various departmental interests involved, bring them into harmony as far as possible, and present to the International Joint Commission the views of the Government of Canada on this question.

Authority should be given to the Board to appoint the requisite number of clerks, or junior engineers to collect and tabulate such data as may be collected; and further (with the concurrence of the Prime Minister), that

the necessary expenses in connection with the carrying out of these proposals be defrayed from the contingencies of the Department of External Affairs.

MUNICIPAL ENGINEERS AND PRIVATE PRACTICE.

An Association of Consulting Engineers was recently formed in Great Britain. At the inaugural dinner it was strongly pointed out that there was a necessity for the new departure. In order to maintain a profession at its highest level it was essential that it should have an external conscience, in addition to the individual conscience of its members, and the new society was due to have a conscience of this kind. It would draw a distinct line between the municipal engineer as he should be, and the municipal engineer when he becomes commercialized and competes with private enterprise.

One of the strong advocates for the association, Mr. J. H. Balfour-Browne, K.C., felt very keenly against the State and municipal engineers being permitted to compete with consulting engineers. They should devote all their time and attention to the work of the municipality, and be adequately paid for doing this duty. If they did devote their time and attention adequately to the work of the municipality, they ought to have no time for engaging in private practice. Apart from this, there was the danger in a municipal engineer acting in a consulting capacity, that he was liable to have a narrow outlook. The variety of the work engaged in by the consulting engineer was his strength, and was apt to give a judicious breath to his decisions, which was invaluable to his client. The Association of Consulting Engineers was doing good work, both for itself and for the public, in keeping up the standard of the profession.

These grounds for the preclusion of State and municipal engineers from acting privately in a consulting capacity are, according to the London *Times*, thin and unconvincing. "For," says the *Times*, "if variety of experience is a source of strength to the everyday consulting engineer it is reasonable to suppose that the municipal engineer would also acquire strength and develop the judicial attitude of mind from occasional indulgence in that class of work. The truth is that the most weighty objections to the acceptance by qualified engineers of private consulting work are based not upon their lack of knowledge, experience, of powers of judgment, but upon ordinary considerations of what is expedient for public servants. In this respect members of the engineering profession holding State or municipal appointments are even more restricted than members of the legal profession in like circumstances. The essential requirement in private consulting work is that when advice is sought upon an engineering matter the engineer selected should be a qualified specialist upon the subject in question; and what the public have to avoid is the employment of a person who poses as a consulting engineer upon every engineering subject that presents itself. In cases of doubt regarding qualifications, an appeal can always be made to the councils of the great engineering societies and institutions."

Some difficulty was encountered during the formation of the new association in discovering exactly what the term "consulting engineer" constituted, as applied in England. The definition proved hard to deduce, although of considerable import, as the association rules are to be applicable only to consulting engineers—professional men to work along professional lines and to advise clients to the best of their ability irrespective of their own pockets.

SURFACE INSULATION OF PIPES.

An investigation of the subject of surface insulation of pipes as a means of preventing damage to underground metallic structures by stray currents from electric railways has recently been completed by the U.S. Bureau of Standards, by Burton McCollum and O. S. Peters. Tests were made of the various substances available for the purpose of insulation of underground structures, including paints, pitch and asphalt dips, pitch and paper and asphalt and felt wrappings, and so forth. Test specimens were made by lining shallow sheet-iron cones with the material to be tested. Before being subjected to the final test each cone was filled nearly full of ten per cent. salt (NaCl) solution and an alternating difference of potential of 80 volts (effective) applied across the coating for 30 seconds, in order to be sure that it was continuous and without flaws. A milliammeter in series with the specimen indicated a defective coating by a kick of the needle. The electrical resistances of the perfect specimens were then approximately determined with a Wheatstone bridge. In the case of the paints these resistances were found to be of the orders of from 10^8 to 10^{11} ohms per square centimetre, while for the wrappings they were much higher.

The final test of the specimens which survived the preliminary test consisted in allowing water and air alternately to come in contact with the coating while a direct potential difference of either four or fifteen volts was applied across the coating. The value of the voltage applied depended on the thickness and other characteristics of the coating. In some of the specimens made up from each material the iron of the cone was made negative and in others positive, while in the case of the paints some of the specimens were subjected to the alternate action of air and water with no potential difference applied, in order to check up the effect of the electric stress.

The alternating contact with the coating of air and water was obtained by filling the cone and allowing the water to evaporate, which took about a week. Readings of the current flow were made at suitable intervals. The first appearance of current flow was taken as indicating the end of the useful life of the specimen as an insulating coating.

The average life of the paints was about 116 days, the maximum life obtained from any specimen being but little more than a year. No conclusive evidence was obtained that the low potential differences applied had any effect in hastening the initial failure of the coatings. The wrappings lasted longer than the paints and dips, but none of them much more than 400 days. It seems from the results that the failure of the coatings must be caused by absorption by them of water, which in time penetrates to the iron, allowing current to flow and destroy the coating by electrolysis. After the first appearance of current flow the destruction of the coating was observed to proceed very rapidly.

The conclusion drawn from the results of the laboratory tests, as recently published in Technologic Paper No. 15, of the Bureau, to the effect that the protection against electrolysis which is obtained by wrapping or painting pipes or other metallic bodies for use underground is only temporary, is borne out by tests on insulated pipes buried in the ground under practical conditions, and also by correspondence with gas and water companies whose experiences lead to the same conclusion.

LETTER TO THE EDITOR.

Cost of the National Transcontinental Railway.

Sir,—I notice in the daily press, under the heading of "Bonded Indebtedness and Annual Interest Charges of Canadian Roads," an item for the National Transcontinental Railway as follows:—

"Line, Moncton to Winnipeg, being constructed by Dominion Government

"Estimated cost guaranteed by Dominion Government, $234,000,000."

The cost of the National Transcontinental Railway for constructing and equipping the road, outside of rolling stock, from Moncton to Winnipeg, will not far exceed $150,000,000. Major R. W. Leonard, Commissioner, and Mr. Gordon Grant, Chief Engineer, estimate this cost to be somewhere around $150,000,000. An item appeared in another Montreal paper as follows:—

"Ottawa, February 19.—The National Transcontinental Railway and its cost is dealt with in an interim report of the Commissioner, Major Leonard, for the nine months of the fiscal year ended December 31. It was tabled in the House last night.

"The total outlay in the nine months was $10,314,994, and up to the end of the calendar year the aggregate was $140,567,147. This is exclusive of interest on capital.

"Track-laying was completed on the eastern section on November 17. There are 1,803 miles of main line, 20 of double track, and 407 of sidings. Steel bridges are 95 per cent. completed.

"The rest of the report deals with contracts awarded during the year for buildings, equipment and supplies."

This proves that my statement is correct, as any competent railway engineer knows that it should not take more than $10,000,000 to $20,000,000 to complete the road, ready to operate in an efficient manner. Any engineer connected with the Headquarters Staff of the National Transcontinental Railway at Ottawa, will affirm that the cost of construction of this road will not be over $160,000,000, and that according to the National Transcontinental Act, the Grand Trunk Pacific will only have to pay interest on the actual cost of the road, which will not exceed $160,000,000.

My reason for drawing your attention to this matter is that I don't think it fair to the credit of Canada and the engineers who were connected with the National Transcontinental Railway, to advertise, not only in Canada but in Europe, that the Grand Trunk Pacific will have to pay interest on the amount of $234,000,000 when the cost of the road will not exceed $160,000,000. The cost is divided approximately as follows:—

Grading	$105,000,000
Bridges	10,000,000
Shops and terminals	10,000,000
Engine houses, stations and other buildings	10,000,000
Salaries, wages and administration expenses	10,000,000
Other items	10,000,000
	$155,000,000

Yours truly,

H. Victor Brayley, A.M.Can.Soc.C.E.

Montreal, Que., March 5th, 1914.

A METHOD OF DETERMINING THE AREA OF CROSS-SECTIONS.

By C. D. Norton,

In the computation of earthwork quantities, the most troublesome detail is the finding of the area of the various cross-sections. On railway construction a 3-level section is generally used, the area of which is found by the following well-known rule:—

Multiply the extreme horizontal width by ½ the centre height, also multiply ¼ the width of the roadway by the sum of the 2 side depths; the sum of the two products is the area required.

If, however, the cross-section contains 4 or more readings, the figure cannot always be divided into soluble triangles, and its area is best found by the following method, which has the advantage that the only figures used, are those recorded in the field book, reducing thereby the chances of error to a minimum. It is also simple and easily checked.

Cross-sections are almost invariably obtained by measuring horizontal distances and vertical elevations, each angular change being noted by a fraction, in which the numerator is a vertical elevation, and the denominator a horizontal distance. As these measurements refer to a base line and a datum at right angles to it, they can be correctly termed *rectangular co-ordinates*.

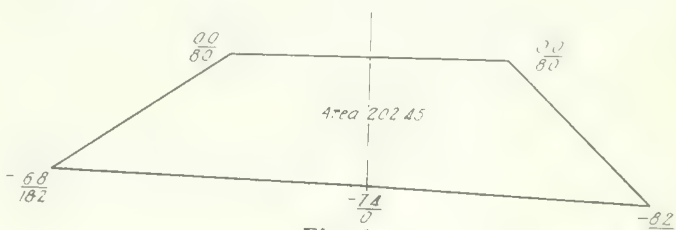

Fig. 1.

A rule to find the area of a figure platted by rectangular co-ordinates can be formulated as follows:—Designate the vertical ordinates as numerators, those above the point of origin being plus, and those below being minus; designate the horizontal ordinates as denominators, those to the right being plus and those to the left, minus. Multiply each numerator by the algebraic difference of alternate denominators. One-half the del. sum of the products will be the area required. If the measurements are taken in feet the result will be in square feet, if in metres the result will be in square metres. The terms may be taken clockwise or not, as may be desired, but in either case a regular order must be observed from start to finish, and strict attention given to the algebraic signs.

To apply the foregoing to earth cross-sections the rule can be worded as follows: Designate cuts and distances to the right as plus, fills and distances to the left as minus. Multiply each numerator by the algebraic difference of alternate denominators, one-half the del. sum of the products will be the area of the figure.

As it is often necessary that calculations be made by men whose knowledge of mathematics is limited the rule can be best understood by following a series of examples.

Example I. (Fig. 1).

Fills.	Alternate Distances.		Differences.	Products.
—6.8	—8.0	0.0	—8.0	54.4
—7.4	—18.2	20.3	—38.5	284.9
—8.2	0.0	8.0	—8.0	65.6
				404.9

One-half of 404.9 = 202.45 = Area.

Distances.	Alternate Fills.		Differences.	Products.
— 8.0	0.0	—6.8	6.8	— 54.4
—18.2	0.0	—7.4	7.4	—134.68
0.0	0.8	—8.2	1.4	
20.3	—7.4	0.0	—7.4	—150.22
8.0	—8.2	0.0	—8.2	— 65.6
One half of 404.90 = 202.45 = Area.				—404.90

It will be noticed that there are two solutions to each figure, one in which the numerators are multiplied by alternate denominators, and one in which the denominators are multiplied by alternate numerators, the result in each case being the same, although the figures in the products are dissimilar. In example No. I. it will be noticed also that the figures resolve themselves into the rule for 3-level sections.

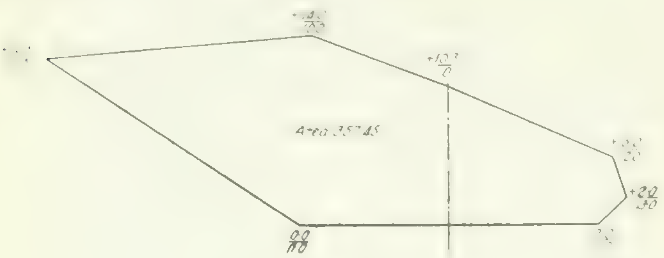

Fig. 2.

Example II. (Fig. 2).

Cuts.	Alternate Distances.		Differences.	Products.
14.0	0.0	—29.5	29.5	413.0
12.3	—10.0	—11.0	1.0	12.3
0.0	—29.5	11.0	—40.5	
0.0	—11.0	13.0	—24.0	
2.0	11.0	12.0	— 1.0	—2.0
5.0	13.0	0.0	13.0	65.0
10.3	12.0	—10.0	22.0	226.6
				716.9
				—2.0
One-half of 714.9 = 357.45 = Area.				714.9

Distances.	Alternate Fills.		Differences.	Products
—10.0	10.3	12.3	—2.0	20.0
—29.5	14.0	0.0	14.0	—413.0
—11.0	12.3	0.0	12.3	—135.3
11.0	0.0	2.0	—2.0	—22.0
13.0	0.0	5.0	—5.0	—65.0
12.0	2.0	10.3	—8.3	—99.6
				—734.9
				20.0
Hence area = 357.45.				714.9

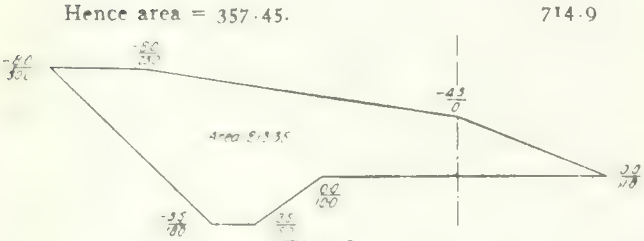

Fig. 3.

Example III. (Fig. 3).

Elevations.	Alternate Distances.		Algb. Diff.	Products.
8.0	0.0	—30.0	30.0	240.0
8.0	—23.0	—18.0	— 5.0	—40.0
—3.5	—30.0	—15.0	—15.0	52.5
—3.5	—18.0	—10.0	— 8.0	28.0
0.0	—15.0	11.0	—26.0	
0.0	—10.0	0.0	—10.0	
4.3	11.0	—23.0	34.0	146.2
				466.7
				40.0
∴ Area = 213.35.				426.7

Distances.	Alternate Elevations.		Algb. Diff.	Products.
—23.0	4.3	+8.0	—3.7	85.1
—30.0	8.0	—3.5	11.5	—345.0
—18.0	8.0	—3.5	11.5	—207.0
—15.0	—3.5	0.0	—3.5	52.5
—10.0	—3.5	0.0	—3.5	35.0
11.0	0.0	4.3	—4.3	47.3
0.0	0.0	+8.0		
				—599.3
				172.6
∴ Area = 213.35.				—426.7

Example IV. (Fig. 4).

Numerators.	Alternate Denominators.		Algb. Diff.	Products.
13.5	15.0	8.0	7.0	94.5
17.6	0.0	20.0	—20.0	—352.0
21.5	8.0	30.0	—22.0	—473.0
21.5	20.0	40.0	—20.0	—430.0
20.2	30.0	44.0	—14.0	—282.8
13.0	40.0	54.0	—14.0	—182.0
11.2	44.0	47.0	— 3.0	— 33.6
8.0	54.0	37.0	17.0	136.0
10.5	47.0	28.0	19.0	199.5
6.4	37.0	25.0	12.0	76.8
11.6	28.0	15.0	13.0	150.8
9.2	25.0	0.0	25.0	230.0
				—1753.4
				887.6
∴ Area = 432.9.				865.8

Denominators.	Alternate Numerators.		Algb. Diff.	Products.
0.0	59.2	67.6	—8.4	
8.0	63.5	71.5	—8.0	—64.0
20.0	67.6	71.5	—3.9	—78.0
30.0	71.5	70.2	1.3	39.0
40.0	71.5	63.0	8.5	340.0
44.0	70.2	61.2	9.0	396.0
54.0	63.0	58.0	5.0	270.0
47.0	61.2	60.5	.7	32.9
37.0	58.0	56.4	1.6	59.2
28.0	60.5	61.6	—1.1	—30.8
25.0	56.4	59.2	—2.8	—70.0
15.0	61.6	63.5	—1.9	—28.5
				1137.1
				271.3
∴ Area = 432.9.				865.8

This method is noted in some text books, but is not in general use, mainly because the procedure is at first a little difficult, but with the aid of the above examples it can be easily understood.

A full mathematical discussion will be found in a book entitled "Traverse Tables," by Messrs. Louis and Gaunt, where the method is applied to the finding of areas of figures platted by Latitudes and Departures.

No less than 40,000 horsepower will be available from the new power site reserve in Boulder Canon, two miles east of Las Vegas, Nev., which the United States Federal Government has approved.

DECAY OF IRON AND STEEL IN ENGINEERING WORKS.*

By W. H. Maxwell, Assoc.M.Inst.C.E.

DURING recent years, the writer has been called upon to give close attention to the question of the relative durability of various metals subjected to corrosive influences, as met with in structural engineering, more particularly in connection with deep-well work for public water supply purposes, in steel bridge work, and in boilers and steam engineering generally.

The remarks which follow are in no sense intended to be a complete survey of the subject of corrosion of iron and steel, but simply to outline a few of the more practical points as met with in practice.

At the outset, it may be observed that, however simple the usual text-book theory may appear in regard to the common phenomenon of the corrosion of metals, such as the rusting of common iron or steel, those who are responsible for the prevention of corrosion in important engineering structures will soon realize that the problem is one of much greater complexity than a case of simple oxidation, as commonly supposed. The underlying causes and remedies for such deterioration are still somewhat imperfectly understood, and, even in the simplest cases, there remains room for fuller investigation.

Complications Affecting Corrosion.—In most cases met with in practice, it is not a question of investigating the action of water and air upon *pure* iron, but the deterioration to be arrested is invariably found to be the product of these substances mixed with numerous impurities, thus giving rise to an almost endless variety of conditions and results. The impurities of water and air vary with the locality, and the precise composition of metal is often a varying and elusive contingency of manufacture, somewhat difficult to trace and control.

Commercial Iron and Steel.—In view of the fact that commercial iron and steel are not uniform in composition, and that water and air are invariably contaminated in numerous ways, it is not surprising that the growth of knowledge on the subject has been slow, and that many of the opinions formed have since proved erroneous.

Want of Uniformity in Composition of Metals.—In the case of ordinary commercial irons and steels, the more soluble constituents dissolve out first, according to the nature of the liquids or other deteriorating influences with which the metals are brought into contact. Different batches of steel cannot be depended upon for uniformity of composition and equal durability under like circumstances.

Great care should be taken to prevent irregularity of composition in iron if corrosion is to be retarded. The greater uniformity of wrought iron, as compared with steel, also renders the former metal more resistant to galvanic activity.

Segregation in Metals.—Steels usually show great tendency to segregate, owing to the different temperatures of solidification of their constituents, and the smaller the proportion of iron present the greater is the want of uniformity due to segregation. Under these conditions, differences of potential exist, galvanic activity is set up, and the steel becomes highly corrodible.

*Extract of paper presented in the Journal of the Institution of Municipal and County Engineers (Great Britain).

Uniformity of Coatings Necessary.—Provided the metal can be completely covered with an efficient protective coating in order to insulate it from other metals or from the electrolyte in which it may be immersed, resistance to corrosion will be increased, but it is essential such coatings should be entirely continuous, otherwise, galvanic currents may be concentrated at points or pinholes, and thus cause greater damage than if uniformly distributed over the entire surface of the metal.

Local Conditions Affect Rate of Corrosion.—The behavior of metal is very largely dependent upon the precise local conditions to which it is subjected; for example, a strong industrial atmosphere may give rise, in the presence of moisture, to a powerful corrosive action. The writer has often experienced the highly damaging effect of fumes from passing locomotives upon mild steel bridge work exposed to such fumes in the presence of moisture.

Practical Observations.—Also, he has found that steam boilers and condenser tubes sometimes become pitted and grooved in a very unaccountable manner. Two or more boilers installed at the same date, made of similar material, fed with the same class of feed water, and worked under like conditions have oftentimes been observed to give widely divergent results—one being in good condition after 15 years' use, whilst another may become seriously pitted within one-fifth of that time. The repair of an old boiler with new boiler plate sometimes hastens the destruction of one or other of the metals, but it is impossible to foretell which metal will be the first to fail. The best classes of iron, such as Low Moor, are invariably more reliable than modern mild steel, which is a composite material involving many uncertain complications.

Metals Immersed in Corrosive Waters.—The writer has closely observed, for many years past, the varying degrees of corrosion occurring in the case of wrought iron, mild steel, and cast iron immersed in corrosive waters in structural works, particularly when these metals are used in juxta-position with gunmetal and other alloys. In the latter case a very marked and rapid deterioration of iron and steel has been observed to take place in certain natural waters, and under conditions such as these, the author has been engaged upon investigations into the question of the most suitable method of lining bore-wells 336 ft. deep by 3 ft. 6 in. diameter, for water supply purposes.

Deep-well Linings.—The usual mild steel linings were found to be inadmissible, owing to their very limited life under the conditions to be dealt with, and cast iron tubes with specially machined points were finally decided upon—a double lining being used through the first 165 feet of impermeable clay with the annular space between the inner and outer tubes grouted up with Portland cement grout. Great care was taken that no machined parts of the metal were exposed to the action of the water—these being protected by bituminous composition, and by closely fitted metal sleeves.

Foundry Skin.—Except where fully protected in this way, the foundry skin of the metal was not allowed to be broken, as this skin was found to have a strongly resistant action to the corrosive tendencies of the water. Should any machined face of the metal be exposed, deterioration will proceed rapidly at that part.

Uniformity and Insulation of Metals.—In all such works where metal must be fixed in contact with corrosive waters, the metals used should be as uniform in composition as possible, and if the employment of different

metals is unavoidable, they should be insulated from each other as perfectly as possible.

Cast Iron More Resistive Than Steel.—Under many circumstances cast iron is much superior to either wrought iron or steel, and the closer the grain of the cast metal the more perfectly will it resist corrosive influences.

Action of Pure Iron, Air and Water.—Absolutely pure iron, if it could be obtained, would be unusually resistant to corrosion, unless placed in metallic contact with dissimilar metals. It is interesting to note that the action of pure water and pure air upon pure iron is but slight, and for all practical purposes negligible, but inasmuch as all these commodities are scientific curiosities of the laboratory rather than matters of ordinary experience, the point is not of direct practical importance, except in so far as it indicates the direction in which causes of corrosion may be expected to lie.

Moisture Hastens Corrosion.—Whilst there are many points still the subject of controversy, investigators appear to be agreed that, unless water is present, iron will not rust in air or oxygen. Natural rain-water and mist show great activity in the oxidation of metals, and water, when saturated with air is strongly corrosive to iron and steel. Corrosion proceeds most rapidly when the metal is alternately subjected to wet and dry conditions, such as at the water-line of iron columns, ships, boilers, water tanks, and the like. Deterioration of the metal at the water-line in boilers is a very generally noticeable condition.

Effect of Deeply Immersing and Burying Metals.—Water surfaces in contact with the atmosphere become more or less saturated with oxygen and the corrosive action of the water is consequently increased. Ironwork is much less corroded when immersed to a considerable depth in water than when placed near the surface, where air gains access.

Acids in Soils.—Deeply burying of metal in the soil has also been observed to have a preservative effect, as free oxygen cannot readily reach it. Should the soil, however, contain acids or acid salts these will soon have a destructive effect on the metal, as also will stray electric currents by the setting up of "electrolysis," resulting in rapid corrosion. It has also been observed that exposure to the action of diffused sunlight stimulates the rate of corrosion of iron.

"Busy" Iron.—Railway metals in active service corrode less rapidly than do similar rails laid in sidings which are little used. It may also be taken generally that "busy" iron, and iron subjected to vibration, has been observed to rust much less rapidly than idle metal subjected to similar corrosive influences. A thick scale of rust on the surface of metal retains moisture and hastens further corrosion.

Painting of Metals to Prevent Corrosion.—In regard to the question of painting or "coating" of metals with a view of preventing corrosion much consideration is needed, or more harm than good may result. A form of specification commonly seen requires "all ironwork to receive one (or two) coats of paint before leaving the manufacturer's works." The wisdom of this is very doubtful, inasmuch as the "mill-scale" on the new ironwork is certain to come away sooner or later as oxidation sets in under the paint, and the latter coating will thus be brought away with the scale. In the use of some proprietary "coatings" it is, in fact, recommended that a first coat be applied and allowed to peel away, should it prove disposed to do so, in order that all scale may be removed therewith, and the subsequent coatings will then permanently adhere and protect the metal.

In the galvanizing and other similar trades the mill-scale is removed by dipping the steel and iron goods in hydrochloric acid solution before coating the metal.

Removal of "Mill-scale."—Before painting iron and steel work, as in bridges, etc., the black oxide scale, or "mill-scale," may advantageously be permitted first to turn to red oxide or rust, and the metal then be thoroughly well cleaned with wire brushes or sand blast. This having been well done, the paint will then find its way direct to the metal and form a much more permanent coating. It is often a difficult matter to remove every trace of mill-scale, but the improved results obtained justify this precaution.

Many engineers now frequently allow iron and steel structures to stand for a while and rust, in order that the mill-scale may be loosened and so come away more freely by scraping and wire-brushing, before any coat of paint is applied.

Rust is capable of setting up galvanic activity, but to a less degree than is the case with magnetic or black oxide.

Necessity of Continuous Coatings.—Numerous "coatings" of varying composition have been largely used on all classes of work in which metals are extensively employed. In the case of steel pipe-line in wet soils or situations, the conditions are severe, and no permanently effective coating is at present available. The application of the coating is also of first importance. It should be absolutely uniform and continuous, otherwise, should there be imperfections, such as small holes, galvanic currents leave the metal plates at these points, and the iron or steel work becomes more quickly corroded than would be the case if the same action took place uniformly over the whole surface.

"Coatings" May Prove Detrimental.—Artificial coatings, intended for protection, may thus not infrequently become sources of danger, and, in the case of some paints, the coarser particles of pigment may induce galvanic activity under the paint. It will be advantageous, therefore, to use a pigment which is a bad conductor of electricity, finely ground, and well incorporated with oil.

R. H. Gaine's General Comment.—The whole subject of the corrosion of iron and steel abounds in curious anomalies, and apparently similar materials do not always behave alike under what may be believed to be identical conditions. The general comment on this subject of Mr. R. H. Gaines, the eminent chemist to the New York Board of Water Supply, is of special interest. In a report on the corrosion of a 38-in. diameter steel conduit at Rochester, New York, it is observed that:—

"The corrosive influences of nature can never be precisely imitated, and, moreover, the time during which laboratory experiments extend is relatively so short that they are of little value compared to actual experience. Besides, practical experience on such subjects is always more reliable than mere laboratory experiments. . . . There is a wide divergence of opinion among metallurgists on the corrodibility of the various forms of iron. Experience at Rochester, Portland, and elsewhere, seems to show that cast iron resists corrosion better than any other form of iron, and wrought iron is less easily corroded than mild steel. As between steel and wrought iron, some metallurgists claim that the difference is slight, but their reported experiments have not been carried far enough to base a final opinion."

Failures of Steel Pipe-lines.—A number of very costly failures, due to corrosion, are on record in regard to mild steel pipe-lines. The use of this material for water conduits was adopted some 25 years ago, and, so far as durability is concerned, may almost be said to be still in the experimental stage. But, apart from the probability of early deterioration, mild steel mains have many advantages from a structural engineering point of view, such as greatly reduced weight, as compared with cast iron, for a given carrying capacity, greater reliability under heavy pressures, and generally increased adaptability to meet the conditions of route of any particular pipe-line.

38-in. Main, Rochester, New York.—The steel pipeline in connection with the Rochester water undertaking, New York, already referred to above, is 38-in. in diameter and 26 miles long, and, within 6 years of being brought into use in the year 1894, rust-hole leakage, due to external corrosion, took place.

Causes of Failure.—The cause of this failure was attributed to "electrolysis," and occurred in parts of the main laid in wet soils. Corrosion is found to be much retarded in dry, sandy or well-drained soils. Subsoil water in contact with steel in such cases is found to produce electromotive force from electro-chemical action, and the electrolytic damage is proportional to the time during which the current acts.

The three leading conditions which brought about serious corrosion in the Rochester main were: The wet soils through which the main was laid, ineffective protective coatings, and want of uniformity in the composition of the steel.

Even in the best and most uniform qualities of steel there exist contiguous areas of different electrical potential, and if the steel tubes lie in contact with an ionized solution, like soil water, corrosion will occur by electrolysis, as in this case.

Failure of 30-in. Main in Australia.—Another case of serious corrosion occurred during recent years in connection with a large and costly steel main 350 miles long by 30 in. diameter, in Australia—the corrosion being first observed about 3 years after completion. The official reports in such cases form an instructive study to those interested in such matters.

Relative Durability of Cast Iron, Wrought Iron, and Mild Steel.—The relative durability of cast iron, wrought iron, and mild steel is a matter of considerable commercial importance. In the case of cast iron, it would appear, in some instances, that no practical limit can be put upon this material when used under suitable conditions. The cast iron flanged pipes supplying water to the great fountains at Versailles were laid in 1685, or 229 years ago, and are stated to be still in use. Evidence is also available of cast iron bridges having been in use over a century and a quarter without visible deterioration from corrosion. Some wrought iron bridges are said to have shown over 60 years' service, but as regards mild steel bridges the life is usually much less, some such structures having become unsafe from corrosion after 25 years' use. In the author's experience, when mild steel bridges arrive at about this age, much annual attention is necessary to cope with deterioration due to corrosion.

Influence of Electrolytic Activity, Strain, etc.—In the decay of metals by corrosion, electrolytic activity is a much more serious factor than was formerly thought, and its action is of a subtle and elusive nature and difficult to stop. Many intricate complications arise, e.g., iron subjected to strain or uneven treatment, generally speaking, corrodes more rapidly than that treated uniformly. A difference of electrical potential exists between strained and unstrained pieces of similar metal, also between tempered and untempered portions. Galvanic activity can therefore be induced by immersing metals under these conditions in electrolytic solutions, and corrosion of the anodic metal results.

In some experiments strained portions of metal were found to be cathodic to the unstrained, and the latter specimen was therefore attacked the more vigorously.

No Rules Generally Applicable.—No general rules appear to be universally applicable, but the important point for engineers to bear in mind is that a difference of electrical potential does exist, and that strain of any kind will induce such change of potential, resulting, when immersed in an electrolytic solution, in corrosion due to galvanic activity. Beforehand, it is difficult to say whether the strained or the unstrained portion will act as the cathode, and so be preserved at the expense of the other, as the difference of potential is small and dependent on the actual local conditions of the case in point.

Differences of Potential.—Differences of potential between two metals placed in the same electrolyte under different conditions do not always remain constant. The potential difference may change in degree, and in some cases even the polarity may undergo reversal. The metal which is at the higher potential corrodes and constitutes the "anode," whilst the cathodic metal will remain unaffected.

Reversals of Polarity.—In cases where reversals of polarity occur, owing to the initial difference in potential being slight, both metals will corrode proportional to the time each has served as the anode.

Potential Difference.—Potential difference depends upon the chemical nature of the electrolyte, on its degree of concentration, temperature, rate of motion and other factors.

Means of Retarding Corrosion.—Corrosion due to galvanic activity can be retarded by securing greater uniformity of composition in the metal, a minimum of segregation as occurring in steel, uniformity of physical condition in the metal, and protection from moisture, which will act as an electrolyte.

Theories of Corrosion.—Although the foregoing observations on the corrosion of metals are intended to bear primarily upon the practical side of the question, a brief reference to the principal theories of corrosion which have been suggested to explain the cause of this great waste and decay which takes place may be of interest in the present connection.

Many theories have been proposed, but two only merit serious consideration, viz.: the acid and the electrolytic theories respectively.

Acid Theory.—According to the acid theory, oxygen, *pure* water and iron may remain in contact indefinitely without producing rust, the presence of a trace, at least, of some acid being essential to the oxidation of the metal. Carbonic acid, being naturally prevalent in air and water, is generally understood to be the primary cause of attack in ordinary cases of rusting.

Electrolytic Theory.—The electrolytic theory, on the contrary, depends upon the solubility of iron in pure water, and maintains that the presence of even traces of an acid is not necessary to its oxidation, but that water

and oxygen alone are essential. This theory depends upon the presence of free hydrogen ions in the purest water, and the experimental work done shows rusting to be principally due to attack from this source.

Differences of Opinion.—As indicating the unsettled state of scientific opinion on the theoretical side of this question, it may be observed that one authority, whose views on the subject command the greatest respect, considers the balance of evidence decidedly in favor of the acid theory, whilst another, of equal eminence, strongly urges the electrolytic doctrine.

Use of Theories.—Whilst the ordinary user of metals may look upon these different theories as of little moment, and regard the fundamental distinctions between them as theoretical rather than practical, it should not be overlooked that a reasonable tentative conjecture respecting the cause of any phenomenon may have its uses as a working hypothesis.

Commercial Importance of Inhibition of Corrosion.—The present may be looked upon as the age of iron and steel, and the commercial importance of the subject of the corrosion of metals can scarcely be over-estimated, inasmuch as in almost every department of constructive work these materials are increasingly used, and, in view of the universally heavy costs of maintenance and renewals due to corrosive deterioration, no problem, perhaps, holds out greater prospects of reward, both to the scientific investigator and to the manufacturer alike, who shall commercially produce more resistant metals than those now available for the general structural requirements of the engineer.

A Swedish engineer has patented a process for the manufacture of cement in electric furnaces, which has been found practicable. Hitherto, the manufacture has been made difficult by the formation of calcium carbide that ruins the cement. The method of overcoming the difficulty consists in adding a metallic oxide to reduce the carbide. Iron oxide has proved a suitable material, and, instead of including this in the charge of the furnace, it has been found sufficient to add the powdered oxide to the cement product taken from the furnace.

In a report by United States Deputy Consul-General Loop of London, to the Treasury Department, it is said that pneumatic grain elevators are used in England by practically all of the large grain handling and milling concerns located at the various ports, and are regarded as being very successful. The average quantity of grain dealt with in an hour by such elevators, may be taken as 100 tons, (ton equals 2,240 lbs.), though the largest plants are capable of dealing with 150 to 200 tons of grain per hour, while smaller ones are in use dealing with as little as 5 tons per hour.

It has been announced in London, England, that work on the tunnelling for the underground railway to be constructed to facilitate the handling of mail matter in England, is to be commenced immediately. Comprehensive plans have been prepared for the project, which show an underground narrow-gauge automatic railway which will link up all the principal railway terminals with the district post offices. Interesting tests were shown recently at Chelmsford with automatic electrical trains working on an experimental railway. The track has an 18-inch gauge, and is half a mile long. It contains curves of very sharp radius, and runs part of the way through a tunnel, such as the Government has decided to construct. The tunnel is just high enough to enable a mechanic to walk upright through it, with a track on each side for trains. Pneumatic tubes are suspended from the roof, and there is provision for telegraph and telephone wires, to the right and left underneath. The cars, which are 2 feet wide, 2 feet high, and 6 feet long, are constructed to permit the carrying of large parcels and mail bags. They carry no operators, but are controlled automatically until they arrive at a station, travelling at an average speed of 30 miles an hour and being despatched at one minute intervals.

REINFORCED-CONCRETE HIGHWAY BRIDGES AND CULVERTS.

AT the annual convention of the American Concrete Institute, held in Chicago February 16-20, 1914, the Committee on Reinforced Concrete Highway Bridges submitted the following tentative recommendations and suggestions. The report was intended to be a preliminary one, to deduce discussion from the members of the Institute. Mr. Willis Whited is chairman of the committee. The other members are Messrs. A. N. Johnson, H. H. Quimby, A. M. Loves and Lemuel Holmes.

Dead Loads.—The following are given as average weights per cubic foot of the materials mentioned, but if the weights of the materials to be actually used are definitely known to be different from those given, the correct weights should be used.

Materials.	Lb. per cu. ft.
Earth filling	110
Plain concrete	150
Reinforced concrete	155
Steel	490
Cast iron	450
Vitrified brick	140
Common brick	125
Granite and limestone masonry.	165
Sandstone	160
Macadam-Telford	150
Pine, fir, etc.	42
Oak and yellow pine	48
Creosoted timber	60

The weight imposed by earth filling should, in ordinary cases, be considered as including all filling included between vertical planes passing through the faces of the abutments.

If, however, the height of the fill exceeds about two-thirds the distance face to face of the abutments, the live load may be neglected and a very considerable proportion of the weight of the filling considered will be supported by friction between it and the approach filling. The amount of load thus transmitted is greatly affected by the cohesion of the soil, of which there is nearly always more or less.

This whole subject requires further investigation.

Live Loads.—Class "A" Bridges—Main thoroughfares leading from large towns.

In view of the extensive introduction of the heavy motor trucks and traction engines, and the probable general use of such vehicles in the future, it is recommended that bridges on main thoroughfares and other roads which are likely to be used for heavy hauling, be designed to carry 20-ton trucks, with axles about 10 ft. c. to c., 14 tons on rear axle and 6 tons on fore axle; wheels about 5 ft. c. to c. Outside of the large cities it is recommended that only one such vehicle be assumed to be on the bridge at any one time, the likelihood of more than one being on the bridge, in a position to produce maximum stresses at the same time, is so remote that this assumption is considered safe. It is advised that such very heavy loads be considered as occupying only the ordinary width of the road, about 8 ft. in width, and about 35 ft. in length. Congested traffic of heavily loaded wagons or motor trucks will rarely impose a load of more than 100 lb. per sq. ft., over a considerable area. The above-mentioned 20-ton truck gives a load of about 140 lb. per sq. ft., on the area actually occupied, but it is considered

extravagant to assume that a large bridge is covered with such heavy loads. One hundred pounds per square foot is thought ample to assume for the loading of spans more than 60 ft. long, in designing the trusses or main girders. It is thought to be safe to reduce this assumed load in the case of longer spans, to the following amounts:

Length of span, ft.	Assumed load, lb. per sq. ft.
80	90
100	80
125	75
200 and over	70

With all intermediate spans in proportion.

The greatest load that is liable to be imposed on a bridge sidewalk, occurs when there is some excitement in the neighborhood, which attracts a large crowd, and for which the bridge affords an especially good point of view. In that case the crowd forms a compact mass, against the railing, not more than 4 ft. deep, making a load seldom exceeding 100 lb. per sq. ft., over a very considerable space. The remaining portion of the sidewalk may be covered by a moving crowd which can scarcely weigh more than 40 lb. per sq. ft. It may be advisable, sometimes, to so design sidewalk slabs, that if a street car or motor truck accidentally gets upon the sidewalk, it will not go through. Such accidents are so rare, that it is thought safe to allow materials to be stressed somewhat beyond the elastic limit in such cases.

Class "B" Bridges—Although it is impossible to determine beforehand, especially in the newer parts of the country, whether any given road is to be used for heavy traffic, it seems extravagant, at least in the cases of larger spans, to design bridges to carry much heavier loads than can be expected to come upon them. It is recommended that bridges of this class be designed to carry 15-ton trucks, with axles 10 ft. apart, 5 tons on the front and 10 tons on the rear axle. This will allow for a considerable overloading of existing motor trucks. It is further recommended, that only one truck be assumed to be on the bridge at one time, in designing the floor system, that it be assumed to cover a width of 8 ft. and a length of 35 ft. and that the remainder of the bridge is covered with a load of about 90 lb. per sq. ft., for spans up to 60 ft.

The longer spans, the trusses and main girders should be designed for the following loads:

Length of span, ft.	Assumed load, lb. per sq. ft.
80	80
100	70
125	65
150	60
200 and over	55

With intermediate spans in proportion.

Sidewalks should be designed to carry the same loads as in the case of Class "A" Bridges.

Special Bridges—City bridges and bridges carrying traffic connected with mines, quarries, lumber regions, mills, manufactories, etc., require special consideration and should, of course, be designed to carry any load which can reasonably be expected to pass over them, bearing in mind the likelihood of heavy traction engines and motor trucks coming into extensive use in the not distant future.

Stringer Loading.—The maximum stress in a stringer, due to a wheel load, occurs evidently when the wheel is directly over it. It is not thought proper to assume any distribution of the load to adjacent stringers, unless the bottom reinforcement in the slab is made continuous. In that case the distribution is proportional to the relative stiffness of the slab and the stringers, said stiffnesses being proportional to the moments of inertia, multiplied by the modulus of elasticity of materials and inversely proportional to the cube of the span. In determining this distribution, due account must be taken of the fact that deflection of the slab decreases toward the end of the stringers, and also of the fact, that whatever load is carried to the adjacent stringers, deflects them also. It is therefore recommended that wherever practicable the bottom reinforcement of slabs be made continuous over the stringers.

Slab Loading.—The distribution in a direction parallel to the supports of a concentrated load resting on a slab, supported at two opposite edges only, evidently depends upon the same principles as those mentioned under "Stringer Loading." The main difference being that what corresponds to the stringer in the former case is of indefinite width in the present case. Adequate theoretical investigations of this question appear to be lacking. For the present it seems fair to assume that the distribution each side of a concentrated load is equal to about one-third the length of the span, and that the cross reinforcement should be designed accordingly, which would require it to have an area of at least one-half of the principal reinforcement. The distribution of a concentrated load through earth filling on the top of a slab does not appear to be very well understood.

Bridges Carrying Electric Cars.—Electric traction is still in its infancy and nobody is able to forecast its future development. It seems probable, however, that it will not be profitable to run cars weighing more than 50 tons each, at a speed that would be permitted on any public road. If very high speeds are desired, the traction company will doubtless be required to operate over its own right-of-way. It is recommended that bridges carrying either urban or interurban electric cars be designed to carry 50-ton cars on two trucks, spaced 30 ft. c. to c., each truck having two axles spaced 7 ft. c. to c. The committee sees no reason for changing the customary practice of assuming that an axle load is distributed over 3 ties.

Loading on Arches.—The deflection of an arch being much less than that of a beam of the same length, the method recommended for determining the lateral distribution of a concentrated load over arch sheeting appears to be different from the distribution over flat slabs. It seems doubtful if the distribution in each direction can be greater than twice the thickness of the arch sheeting. This question should be investigated.

Stresses in Arches.—As all arches that are not provided with hinges act as elastic arches until cracks are formed, due to excessive tension at some point or points in the concrete, it is manifestly proper to calculate the stresses in them according to the elastic theory.

As concrete is a very poor conductor of heat, it is not thought necessary in calculating reinforced-concrete arches, to assume so much variation in temperature as is usual in designing steel structures, although the outside layers of concrete are of nearly the same temperature as the surrounding air, and those layers are stressed more heavily than any of the others, it is thought that an extreme variation of about 80° F. in the Northern States is sufficient to allow for, in any case, and that can be reduced if the arch ring is thicker or if there is much earth filling in the spandrels.

Bearing Power of Piles.—The usual formula for the safe bearing power of wooden piles is:

$$B = \frac{2\,W\,H}{S + 1}$$

in which,

W = Weight of hammer in pounds,
H = Height of fall of hammer in feet,
S = Penetration in inches per blow, average of last few blows.

If reinforced-concrete piles are molded before being driven, the head of the pile is usually cushioned more or less, and the pile is generally much heavier in proportion to the weight of the hammer than is the case with wooden piles. It is recommended that the hammer should be at least as heavy as the pile.

If concrete piles are molded in place, measures should be taken to prevent damage to them by the driving of neighboring piles or otherwise.

Bearing Power of Soils.—This subject is under an investigation by a committee from the American Society of Civil Engineers. It may be some years before their final report is submitted and even that will be subject to revision from time to time, as human knowledge is extended. In the meantime the committee would submit the following preliminary table:

Material.	Safe bearing power, tons per sq. ft.		
Quicksands and wet soils	0.1	to	1.0
Dry earth, according to depth below surface	1	to	3
Moderately dry clay confined	2	to	4
Dry stiff clay	4	to	6
Sand confined	2	to	6
Sand compact and cemented	4	to	8
Gravel cemented	8	to	12
Rock	25	to	200

Foundations should be carried down below frost unless they are on rock and thoroughly drained. Soil that contains the roots of plants is generally compressible. Undisturbed soil is much less compressible than filling or similar soil, even though it has been in place many years. The bearing power of sand, gravel and dry clay increases rapidly with the depth below the surface of the ground. None but the smallest structures should be founded on earth filling.

The pressure of earth against abutments, wingwalls and retaining walls varies so widely with the character and condition of the earth in question, that nothing more than a few general suggestions can be given. It is hoped that the committee from the Society of Civil Engineers, which is studying the bearing power of soils, will take up this subject also. In ordinary cases where the filling is well drained its pressure will seldom be more than that of a liquid weighing 25 lb. per cu. ft., and is frequently much less. The pressure due to land slides is often several times this amount. If the filling is clayey and is allowed to become waterlogged, its lateral pressure is greatly increased. The effect of the freezing of the filling must also be considered.

Required Waterway.—The usual formula for waterway for culverts is:

$$a = C A^{\frac{3}{4}}$$

in which,

a = Required area of culvert in sq. ft.
A = Drainage area in acres.
C = A constant, depending on the length and character of the drainage area and may vary from about 0.3 to 2.0 in regions where the mean annual rainfall is about 50 in.

The capacity of the culvert will be much greater if the wingwalls are flush with the abutments and flare about 30°, the sides and bottom of the culvert are smooth and straight, and the bottom has a good slope.

If reliable information covering a number of years can be obtained regarding the adequacy of the old bridge crossing the same stream, it is much more useful in determining the size of a culvert or bridge than any formula.

PANAMA CANAL EXCAVATION.

The grand total of Panama Canal excavation to February 1, 1914, was 216,966,610 cu. yd., leaving 15,386,390 cu. yd. remaining to be excavated under the revised estimate of July 1, 1913. The total excavation for the month of January was 1,514,972 cu. yd., as compared with 1,581,726 cu. yd. for December. The wet excavation amounted to 1,118,464 cu. yd., and the dry excavation to 396,508 cu. yd.

ALASKA TIMBER CONTRACTS.

Arrangements have been made by the United States Forest Service to advertise for bids for 40,000,000 feet of Sitka spruce and hemlock timber in the Tongas National Forest, Alaska. The timber is in two bodies, the larger consisting of 38,000,000 feet on the Fish creek watershed, Baranoff Island, 30 miles north-east of Sitka, and the other 2,000,000 on Thorne River, Prince of Wales Island. Six years will be allowed for the removal of the larger tract and two for the smaller. The initial rate of $1 per M. for the spruce and 50 cents per M. for the hemlock, with two optional increases in the stumpage rates not to exceed 50 cents per M. in the Baranoff tract and one such increase in the Prince of Wales tract, is provided for.

RIVER IMPROVEMENT IN RUSSIA.

It is reported from St. Petersburg that the Russian Government has given to an American syndicate of capitalists the contract for the contemplated improvements on the Volga River and its tributaries. The work includes extensive dredging, is to be supervised by an American staff of engineers, will be finished within 5 years, and is estimated to cost 500,000,000 roubles.

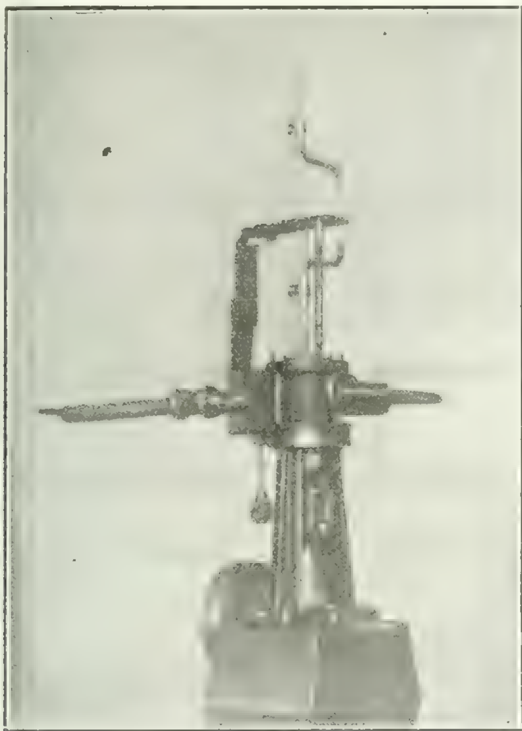
Fraser and Chalmers of Canada, Limited, 4 Phillips Place, Montreal, have been appointed Canadian agents for W. H. Allen, Son and Co. Limited, of Bedford, England, engineers and builders of steam, hydraulic and d.c. electric machinery.

Canadian Allis-Chalmers, Limited, Toronto, have been appointed exclusive agents for Canada and Newfoundland, of the Avery automatic scales. The parent factory, at Birmingham, Eng., was established almost 200 years ago. The scales are of value in power plant installations for checking the amount of coal and water feed to boilers, in weighing liquids for sugar and oil and other industries, and in cement plants to determine automatically the proper proportions of the various ingredients. The Avery scale in the Canadian Government elevator at Port Colborne is said to be the largest automatic grain scale in the world.

A NOVEL USE FOR A STEAM ENGINE.

Mr. W. L. McLaren of Ottawa sends in the following interesting description of an impromptu method which he applied to cutting irregular holes and spaces in some thin pieces of metal. Finding that drilling and filing these holes by hand promised to occupy a considerable time he devised a method of using a small upright steam engine which he had made several years ago for experimental purposes. The stroke and bore of the engine were each about 1 inch in dimension.

After removing the piston rod and head, a hole was drilled the size of the former in the centre of the cylinder head, and the shank of the saw, being of the same cross-sec-



tional area as the piston, was run entirely through and connected with the cross head in the same position is the piston.

To reduce the number of moving parts, the eccentric and eccentric strap were removed, and the fly wheel of the engine was then belted to the countershaft on his bench lathe.

A table was improvised, using an ordinary clamp and a couple of pieces of flat iron as shown in the accompanying photograph, the pieces being bolted so as to allow of small adjustments. The outfit could be readily taken down or set up in a few minutes' time.

The question arises why the shank of the saw was not merely connected directly to the piston and the apparatus run by steam. This was not feasible as steam was not available, and because the engine was of such a small size that it would hardly generate sufficient power to do the work; whereas, when the outfit is operated by belt it transmits sufficient power and allows a variation of speed by the changing of the speed of the countershaft.

By plugging the hole in the centre of the cylinder head the steam engine may again be used for its original purposes.

The Dominion Engineering and Inspection Company, of Montreal and Toronto, have been appointed to inspect the fabrication of the travelers to be used for placing the centre span of the Quebec bridge. These travelers will be manufactured by the Structural Steel Co., Limited, for the St. Lawrence Bridge Company.

SOME FEATURES OF THE MACHINERY EXHIBIT AT THE PANAMA PACIFIC-INTERNATIONAL EXPOSITION.

Such great advances have been made during the last decade in the perfecting of methods of shaping metals, that many of the machines for this work are of extreme interest. Also, the improvement in the processes of producing purer metals has contributed its part toward making many of these methods possible and practicable. Every visitor to an old-time machine shop, and such a shop existed up to a very few years ago, recalls the long lines of shafting, pulleys and belts overhead for transmitting power from the engine that drove the shop to the machine that did the work. All, or nearly all, of this arrangement has now given way to the system of driving each machine by electric motor. The steam engine in the shop no longer drives a long line of shafting, pulleys and belts, but drives, instead, a generator, supplying power to the motor mounted on each machine, and, in this way, any one machine may be operated while the remainder of the shop is silent.

The rapidity of work always counts if quality is not sacrificed, and the use to-day of special steel alloys for making cutting tools has rendered possible high speeds of cutting thought impossible a decade ago. Some of these high speed steels are so hard and tough that they can cut an enormous chip from a piece of metal, making both chip and tool point red hot, yet not wearing away unduly the point of the tool.

These machine tools include lathes, planers, shapers, drills; boring, milling and slotting machines, besides tools for special kinds of work. In fact, a milling machine might be called a special tool, as it can do a remarkable variety of intricate work in shaping metal, and its precision is far greater than can be obtained by hand work.

Among the most interesting of the special machines that will be shown at the Panama-Pacific-International Exposition in celebration of the completion of the Panama Canal is the screw-cutting machine, which makes not only wood screws and bolts, but a great variety of articles that are cut from a revolving piece of metal, such as lock tumblers, sewing machine shuttles, hollow nipples for gas fixtures, and the like. These machines are almost human, and an intelligent boy in a shop can look after the operation of a dozen of them. After the machinist sets one of these machines with the proper tools for cutting any of the shapes required, all that need be done further is to feed a 16 ft. rod of metal into the machine and set it going. The machine automatically cuts from the end of this metal the screw or bolt or other article, moving about as if human hands were handling the piece and finally finishing it and dropping it into a box. The machine of its own accord feeds the rod further in, so that another article may be made and so on until the rod is entirely used up, and if another rod is not put in immediately the machine stops of its own accord.

Another extremely interesting and recently developed class of machines is composed of those for grinding curved or flat surfaces. These do not use steel tools, but use various wheels made up of emery or other hard grinding material, which revolve very rapidly and perform the required work. In this way, surfaces may be ground to far truer shape than by any other process yet known: for example, the smooth parts of an automobile engine crank can be cut from the rough forging in a remarkably short time.

The metal presses form still another class of special interest. There are many varieties of these for pressing such things as rifle cartridge cases, lead pencil ferrules, collar buttons, small tin boxes and many other articles. These are made from flat discs of metal, and many of them are shaped

completely in one motion of the machine. An interesting process accomplished by one of these machines of the heavy type is that of pressing hubs for automobiles or other vehicles. A hub is pressed, in about 20 different motions of the machine, from a steel disc 15 inches in diameter, and 3/8 of an inch thick. This pressing is done with cold metal, only occasionally is the steel heated to redness to anneal it and keep it from cracking, but it is cooled again before further pressing.

The cutting and shaping of metals is so remarkable that such machines as these, that will be exhibited at the Exposition, will be highly instructive.

NOVA SCOTIA STEEL AND COAL, ANNUAL REPORT.

The annual report for 1913 of the Nova Scotia Steel and Coal Company, recently published at Montreal, stated that the demand for the company's products during the early months of the year had been good. During this period a large tonnage was booked at fair prices sufficient to keep the mills fully employed until the closing weeks of the year, the result being that the outputs of iron ore, pig iron, steel ingots, billets, bars and forgings all showed substantial increases over previous years. Referring to the Wabana iron ore property, the report stated that the company's holdings under title from the Crown now covered 91 square miles; that the submarine development had been further extended by the opening up of levels, cross-cuts, headways and rooms; and that the ore won from this section of the property was over 40 per cent. greater than that of the previous year. It was also reported that good progress had been made in the sinking of the new Jubilee shaft, which would be equipped by 1915 for an output of 1,500 tons per day. A new open-hearth steel furnace was completed during the summer, and a number of improvements to plant and equipment had been carried out.

Investigation of water power development facilities in Nova Scotia has shown that that province has many rivers with capacious lakes for storing purposes, and with a fall from 15 to 100 feet, where from 100 to 30,000-h.p. could be developed at a very reasonable cost. The River Mersey is one of the largest rivers in Nova Scotia. It has a fall of 248 feet from First Lake to tide water, a distance of 17 miles. For power developments already exist on the river, occupying nearly 6 miles of its lower reaches. The whole river has lately been surveyed. It is proposed to raise the level by 20 feet to provide for storage for future developments. Three additional dams are to be built. These dams will transform the river into a series of mill ponds. The total amount of continuous 24-hour shaft horsepower available on the Mersey is estimated at 29,830. The development of this river means the establishment of various new industries in Queen's County.

BACK COPIES WANTED.

One of our subscribers, anxious to bind his copies of *The Canadian Engineer*, lacks the following issues: Aug. 13th, 1909; Sept. 17th, 1909; Dec. 10th, 1909; Jan. 25th, 1912, and would be glad to pay 25 cents per copy for any of them. Will subscribers who happen to have these numbers, and who do not care to keep them, kindly send them in to this office in order that they are put into the hands of the party interested?

Coast to Coast

Winnipeg, Man.—Before proroguing, the Manitoba Legislature passed a bill to grant $2,500,000 for good roads in Manitoba.

Port Arthur, Ont.—The annual report of the city engineer of Port Arthur for 1913 shows a total expenditure on civic works of $889,749.70.

Brantford, Ont.—At the inaugural meeting of the Brantford Board of Trade for 1914, the purchase of the street railway was strongly recommended.

Saskatoon, Sask.—1913 commenced with a civic deficit of $36,280, and finished with a surplus of $15,130. This is shown by the city auditor's final figures recently presented to the city council.

Toronto, Ont.—Toronto received from this February's street railway earnings $72,057.90, compared with $65,156.95 for February, 1913. The total receipts were $461,274.45; and in 1913, $434,380.17.

Sydney, N.S.—It is reported from Pittsburg, Pa., that within the past several weeks, the Dominion Iron and Steel Corporation of Sydney, N.S., has made sales aggregating nearly 20,000 tons to Philadelphia and New England buyers.

Ottawa, Ont.—The report of the eighth year of operation of the Ottawa Light, Heat and Power Company showed a total net revenue for 1913 as $297,766; while the gross revenue was $834,662, an increase of $54,688 over 1912. During the year $808,331 was expended on new equipment.

Edmonton, Alta.—As soon as the Edmonton city council passes the estimates for the civic works proposed for 1914, it is planned to commence immediately the new system of scavenging. It is believed that greater efficiency will be gained and that also a saving of about $25,000 per year will be effected.

Edmonton, Alta.—The monthly report of the Edmonton power house for December, 1913, which was recently received by the city commissioners, shows a surplus of $9,404; also that the revenue derived from the electric light department was $48,872; street railway, $15,124; and from the waterworks department, $10,480.

Ottawa, Ont.—That portion of the main line from Ottawa to the West on the C.N.R., joining with the Toronto-Winnipeg line at Capreol, is expected to be completed before the end of 1914. Some 150 miles of steel have now been laid; and it is expected that within four months the grading of the line will be entirely completed.

Brandon, Man.—The estimates of the city of Brandon for 1914 allow to the finance committee $52,000 in contrast to $81,000 granted in 1913; to the health department $21,297, as against $22,600; to the board of works department, about $36,000, an increase of about $5,000 over last year; and to the fire and light departments, $65,000, whereas in 1913 an expenditure of $61,500 was allowed.

Moncton, N.B.—The report of the Minister of Public Works for New Brunswick shows an expenditure on ordinary bridges of $173,910.36 out of an appropriation of $272,500; on permanent bridges, $525,123.20; on roads, $138,236.12 out of an appropriation of $272,500; on buildings, $27,101.58 out of an appropriation of $30,500; and on wharves, $16,985.91, out of an appropriation of $17,000.

Saskatoon, Sask.—The city council will make formal application to the local government in the very near future to pass upon new by-laws to the extent of $553,586.05, made up

as follows:—various civic public works contemplated, totalling $293,755; excess expenditure on by-laws already passed, $167,500; and expenditure on works completed or intended to be completed, for which by-laws have not been passed, $92,331.95.

Hamilton, Ont.—The financial statement of the Hamilton hydro-electric department shows a total expenditure on plant up to the end of February of $541,552; and for the year ending December, 1913, a surplus of $5,494 is reported. The principal items of revenue for the year were:—commercial lighting, $22,203; house lighting, $34,451; power, $28,968; and waterworks, $15,542; and the payment of the city to the Provincial Hydro-Electric Commission for power was $47,307.

Port Mann, B.C.—One of the projects which the C.N.R. has under way in British Columbia is the laying out at Port Mann of an immense series of shops and yards which will cost when completed, millions of dollars. The yard accommodation will find room for over 10,000 cars, while an elaborate scheme of trackage, round houses, shops, wood turning mills, and all the adjuncts of a great modern railroad yard and shops will be featured in the most modern and efficient way.

Moose Jaw, Sask.—The report of Moose Jaw's electrical plant shows a tentative financial statement which estimates that the surplus of receipts over expenditures in 1913 will be around $17,000. The total output at the switchboard for the year was 3,762,470 k.w. hours, which is the largest yearly output in the history of the plant. The total amount sold was 2,725,916 k.w. hours. Also the report states that in 1908 the peak load attained was 209 k.w., while in 1913 the highest point reached was 1,475 k.w.

Hamilton, Ont.—The McKittrick bridge to be constructed on King Street West, Hamilton, and the approaches to the bridge, are estimated to cost $110,419, exclusive of the cost of piling. The total cost of the bridge was placed by City Engineer Macallum, including a 120-foot addition to the structure, at $135,000; but so far the cost compiled from tenders submitted and recommended is under this estimate. The Hamilton Bridge Works purpose commencing at once work upon their contract for the superstructure.

St. John, N.B.—The St. John Railway Company reports a successful year's operations, showing a net profit of $66,328.85. A loop extension 1½ miles long has been added to the trackage; new car barns and repair shops, completed; new boiler house and stack in connection with the power plant, erected; considerable new equipment in the power house, installed; and new street cars, purchased. The gas and electric services have been extended and extensive improvements have been made to the company's Seaside Park.

Toronto, Ont.—The public accounts submitted on March 3 in the Ontario Legislature, which show total receipts from all sources for 1913 of $18,472,638, and a total expenditure of $16,091,672, include among the heaviest items of expenditure:—colonization roads, $406,034; Hydro-Electric Commission, $139,592; public buildings, $2,778,689; roads in New Ontario, $1,063,655; advances to the Toronto and Northern Ontario Railway, $950,000; and good roads statutory fund, $288,367. The accounts as presented show a surplus of over two million dollars, but the Government figures a net surplus of $320,000.

Edmonton, Alta.—$41,000 has been subscribed by Edmonton people toward the $50,000 fund to be raised by the Edmonton Industrial Association to explore the natural gas fields at Vegreville. Contracts for boring will be awarded within 10 days. Experts, formerly in the employ of the Governments of Mexico and China, report that commercial gas should be reached in the first well at less than [illegible] feet, in the event of which it will not be necessary to sink more than 1,300 feet on the other two. If the exploration work is successful the industrial association will turn the fields over to the municipality at actual cost.

Newcastle, N.B.—The wireless station at Newcastle is fast nearing completion. One of the two powerful engines, each of 200 h.p., has been erected and tested satisfactorily. The engines are of the Diesel type, burning crude oil, and were manufactured in Legano, Italy, by the Franco Tosi Co., and erected under the personal supervision of Mr. Oslander, of that firm. The work of installing the dynamos and electrical apparatus has been done by Mr. Phael, of Berlin, Germany. Although no messages have been sent from Newcastle, several have been heard in passage from one station to another, mostly from the Glace Bay station.

Prince Albert, Sask.—The Provincial Government is being urged to put in operation the act passed at its last session to provide for the raising of further funds to finance the Prince Albert hydro-electric undertaking. The plant is located at La Colle Falls, and already $840,000 has been spent by the municipality in its construction; but the difficulty confronting the city and hindering progress on the scheme is that no provision has been made for disposing of the power when it has been developed. The original estimate of the cost of the work was placed at $800,000. It is stated, however, that to complete the project satisfactorily, an additional $1,000,000 will be required.

Swift Current, Sask.—The water has been turned on in the new water supply at Swift Current. A dam of 100,000,000-gallon storage capacity has been constructed by the Ambursen Hydraulic Construction Company, and this will provide for a population of 30,000 with a daily consumption of 50 gallons per head. The dam was commenced in August and finished on December 24 at a cost of $100,000. But the pipe line from the dam to the sedementation basement, which was laid by the McManus Construction Company, was completed only within the past two weeks. This main consists of an 18-inch and a 12-inch cast-iron pipe, and exclusive of the land value, has brought the total cost of the new water supply project up to $150,000.

Vancouver, B.C.—With the exception of a 56-mile section south of Albreda Summit, grading has been finished on the Yellowhead Pass-Kamloops portion of the C.N.R. Grading operations from the eastern end of construction have been completed from railhead near Yellowhead to Albreda, a distance of 75 miles; and track laying will be started early in the spring from both ends. Steel has been installed to mile 121 from Kamloops and five miles south from Yellowhead Pass. Several bridges have to be built south of Albreda Summit over the upper reaches of the Fraser River, and a viaduct is now in course of erection over Lyon Creek, a big gully 122 miles north of Kamloops. The latter will be 1,450 feet in length and will be one of the largest bridges on the section.

Victoria, B.C.—The Provincial Government has cut its estimates of expenditure for the year beginning on April 1 by over $4,000,000 less than the estimates furnished for 1913. The estimates call for an outlay for all services of $13,742,000.40, the supplementaries for the year 1913-14 come to $1,298,179.07, and those for the year 1912-13 to $210,438.91 more, or a total to be voted this session of $15,250,627.58. Last year there was voted a total of $19,003,316.50. The revenue estimated for the coming year is $10,048,915.13, which is $277,170 less than was estimated last year. Among the itemized estimates, there is included an expenditure for public works and buildings of $2,319,500; roads, streets, bridges and wharves, $2,861,000; subsidies, steamers, ferries, and bridges, $96,075.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page 90, a directory of such societies and their chief officials.

TORONTO BRANCH, CAN. SOC. C.E.

On the evening of March 5th, the members of the Toronto branch of the Canadian Society of Civil Engineers met to discuss the draft of standard specifications for concrete and reinforced concrete as presented at the last annual meeting of the society. (See *The Canadian Engineer*, January 22nd, 1914, page 198-203.) About 50 members of the branch were in attendance. Mr. A. F. Stewart presided.

Several hours were spent in an interesting discussion of the specifications. Among those who took part were Prof. P. Gillespie, Prof. C. R. Young, Messrs. C. W. Noble, A. W. Connor, D. A. Molitor, H. F. H. Hertzberg, Frank Barber, W. Monds, E. R. Clarke, C. S. L. Hertzberg, E. P. Muntz, T. R. Loudon and A. H. Harkness.

The discussion involved quite a number of clauses in the proposed specifications, relative to both design and workmanship. Among them might be mentioned proportioning of Tee-beams; vertically reinforced columns; use of re-rolled reinforcing bars, spacing of rods; requirements as to sizes of gravel and sand; percentage of compressive stress to ultimate compressive strength; reinforced cinder concrete; proportioning of columns; the use of stirrups; the weight of 1 cu. ft. of cement as 87½ lbs.; modular ratio; bending moments of beams and slabs; form work; measurement of materials; machine mixing; temperatures of placing concrete, etc.

The scope which the specification should have was likewise thoroughly discussed, it being felt by some that the specifications of the Canadian Society of Civil Engineers should be drawn up as a guide to establishing uniformity in design among its members. Others felt that the specification might be complete in itself so that it could be referred to as occasion required by the engineer in his own specifications, in such a way that points not covered in his specifications, might be dispensed with by a clause requiring compliance with the standard specifications on concrete and reinforced concrete of the Canadian Society of Civil Engineers.

Another point that received a small amount of consideration was one in connection with the advisability of embodying in the specifications clauses covering flat slab design.

It was decided by motion to furnish each member with a copy of his discussion in order that he might prepare it for submission to the committee on reinforced concrete.

The meeting was in accordance with the resolution adopted at the annual meeting in Montreal, whereby the draft was to be subjected to a discussion by the branches, the discussion to be submitted to the committee with instructions to report to the Council of the Society.

The Toronto branch held a midday luncheon at the Woodbine Hotel on Thursday, March 12th. Mr. Geo. G. Powell, Deputy City Engineer, Toronto, was the speaker. A good representation of the members of the branch was present.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

On Thursday, March 5th, Mr. J. Stadler addressed a monthly meeting of the Society in Montreal on the subject of "Pulp and Newspaper Manufacture."

NATIONAL CONFERENCE ON CONCRETE ROAD BUILDING.

The first National Conference on Concrete Road Building was held in Chicago, February 12th, 13th and 14th. The attendance was between 300 and 400, comprising engineers, contractors, laboratory experts, highway officials and cement representatives. During the sessions 14 reports and six addresses were presented, a notable feature of them all was the earnest endeavour on the part of the speakers to supply the demand for accurate data and scientific knowledge concerning road construction, serviceability and permanence. Although the proceedings of the Convention was restricted to concrete roads alone, with little or no reference to any other type, the subject in itself was found by no means narrow and the sessions produced some valuable information and animated discussion. The conference will undoubtedly result in a greater interest in the general subject of road building, and the educative work associated with the meeting will make itself felt throughout the country.

The results of the Conference were summarized in the recommendations of the Committee on Resolutions, the important points of which are briefly abstracted as follows:—

1. The aggregates should be clean and hard.
2. The sand should be coarse and well graded.
3. A rich mixture should be used.
4. The materials should be correctly proportioned.
5. The materials should be thoroughly mixed.
6. The inspection should be intelligent and thorough.
7. When in doubt, reinforce the pavement.
8. The sub-grade should be of uniform density, thoroughly compacted and drenched with water immediately before placing concrete.
9. The concrete should be of a viscous, plastic consistency.
10. After placing, the concrete should be immediately covered and kept moist and not opened for traffic for four weeks.

Besides the addresses, the principal reports received and discussed dealt with the following topics:—Contraction and Expansion of Concrete Roads; Aggregates for Roads; Preparation and Treatment of Subgrade Reinforcement.

Summaries of reports and addresses will shortly appear in *The Canadian Engineer*.

AMERICAN ROAD BUILDERS' ASSOCIATION.

The 11th annual convention of the American Road Builders' Association will be held early in December next in Chicago.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The Toronto section of the A.I.E.E. held its third regular meeting for the year on the evening of March 6th. Mr. Geo. H. Hill of the General Electric Company, Schenectady, N.Y., presented a paper entitled "High Tension Direct Current Railways." The address was illustrated by motion picture and lantern views.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.

At its meeting on February 27th, the members of the Engineering Society of Queen's University were addressed by E. L. Cousins, B.A.Sc., Chief Engineer, Toronto Harbor Commission, who spoke upon the proposed improvements to the Toronto water front. In the course of the description of the supposed development of the Toronto harbor improvement (which was outlined in part in *The Canadian Engineer* for November 21st, 1912), Mr. Cousins announced some interesting points that have lately developed in connection with the scheme.

AMERICAN CONCRETE INSTITUTE.

The 10th annual convention of the American Concrete Institute, the new name adopted last July by the National Association of Cement Users, was held in Chicago, February 16th to 20th. Between 150 and 200 members and guests were in attendance. The annual Chicago Cement Show, which was held February 12th to 21st, in conjunction with the Convention and also with the Conference on Concrete Road Building made Chicago a rendezvous for road builders and manufacturers of cement and road building machinery to such an extent that the broadening use of concrete was strongly reflected in many ways.

A review of the technical committee reports and papers presented at the annual convention will be published in an early issue of this journal.

ILLINOIS WATER SUPPLY ASSOCIATION.

The sixth annual meeting of the Illinois Water Supply Association was held at the University of Illinois, March 9th to 11th. The subjects covered by addresses and reports were broad and included practically every phase of the problem of obtaining and conserving an abundant supply of pure water for the towns and cities of the State.

Among the papers which were read might be mentioned the following:—Removal of Anchor Ice by Means of Air; Remodeled Underdrain System for a Mechanical Filter Plant; Water Treatment for Railroads; Underground Movement of Contamination; Locating Leaks in Water Mains by Means of Water Hammer; the Use of the Nitrite Test in Determining the Source of Pollution of a Water Supply; the Addition of Inorganic Salts to Culture Media Employed in Water Analysis; Public Control of Water Supplies in Illinois; Rates and their Relations to Meters; Surface Water Supplies of Illinois; Value of Mathematics in Economic Design of Some Water Works Detail; Relations of Out-of-Pocket Cost to Rate-Making; Necessity for State Supervision of Water Purification Plants; and others.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Deven, 47 Slate Street, Troy, N.Y.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

AMERICAN SOCIETY FOR TESTING MATERIALS. —Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

AMERICAN PEAT SOCIETY.—Eighth Annual Meeting will be held in Duluth, Minn., on August 20, 21 and 22nd, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

PERSONALS.

H. DOUGHTY, superintendent of the Regina Municipal Street Railway, has submitted his resignation to the City Council, to take effect April 30th.

It was announced in these columns recently that GEO. D. MACKIE had been appointed city engineer of Moose Jaw. His correct official title is Engineer Commissioner.

PROF. J. ANSEL BROOKS, of Brown University, on March 2nd, delivered an illustrated lecture on "The Principles of Efficiency Engineering Applied to Highway Engineering," before the Graduate Students in Highway Engineering at Columbia University.

MAJOR W. W. CROSBY, M.Am.Soc.C.E., Chief Engineer, Maryland Geological and Economic Survey and Consulting Engineer, Baltimore, Md., on February 28th delivered an illustrated lecture on "The Value of Cost Data in Highway Engineering," before the Graduate Students in Highway Engineering at Columbia University.

FILIBERT ROTH, Dean of Forestry at the University of Michigan, addressed a meeting of the University of Toronto Foresters' Club, on March 5th. Prof. Roth was born in Germany, but came to America over 40 years ago. Since then he has seen almost every phase of life on the ranch and in woods, city and university. His forest school is now the largest in America.

ROBERT W. ANGUS, Professor of Mechanical Engineering, University of Toronto, delivered a lecture on the proposed Victoria Park water supply scheme for the City of Toronto, to a meeting of the Engineering Society of the University, on Monday, March 9th. The scheme, in connection with which Prof. Angus was consulting engineer to the Department of Works, was outlined in *The Canadian Engineer* for January 22nd. (Page 227-232.)

W. W. PEARSE, a prominent structural engineer of New York City, recently addressed the Ontario Association of Architects on "Structural Problems in New York Fireproof Buildings." Economical design of steel for floors, different types of fireproof floors were discussed and wind bracing and foundations analyzed. There was a special discussion on reinforced concrete and some very useful formulæ were given for the architects' use, as Mr. Pearse pointed out, Toronto and New York codes are similar in many respects.

OBITUARY.

E. R. DOE, head of a prominent Victoria contracting firm, died recently at the age of 47. Mr. Doe, formerly a native of Norway, with his brother, had undertaken and successfully completed a number of important engineering contracts in British Columbia during the past ten years. At the time of his death, he was engaged in constructing a steel bridge over Arbutus Canyon, B.C.

The Imperial Wire and Cable Co., Limited, and the Northern Electric and Manufacturing Co., Limited, have been consolidated into one company, which will be known in future as the Northern Electric Co., Limited. The new company will continue to operate without change in management.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21413—February 27—Suspending, pending investigation by the Board, tariffs of the G.T.R., Wabash R.R., Central Vermont Ry., Rutland R.R., Michigan Central R.R., and Toronto, Hamilton, and Buffalo Ry., C.P.R., and Quebec Central Ry., requiring additional railway tickets for exclusive use of drawing-rooms or compartments in sleeping or parlor cars.

21414—February 9—Approving detail plans of the subways to be constructed by the C.P.R. Forsyth Branch, in the City of Maisonneuve, namely: Desjardins St., Pie IX. Ave., Jeanne D'Arc St., D.Orleans St., Bourbonniere St., Charlemange St., Lasalle St., and Latourneux St.

21415—February 23—Relieving, for the present, the G.T.R. from providing further protection at the crossing of the 4th Con., Twp. of Raleigh, or the third public road west of Chatham station, Ontario.

21416—February 26—Authorizing the Kaministiquia Power Co. to construct the said temporary trestle and sluice way across the C.N.R. at a point 1,390 feet west of Kakabeka Falls station, Ont.

21417—February 27—Approving plan of the Edmonton, Dunvegan and B.C. Ry. showing design for fifty-foot half-deck plate girder span of bridge to be constructed over the Athabasca River, at mileage 131 west of Edmonton, Alta.

General Order No. 121—Rescinding General Order No. 109, as from March 1st, 1914.

21418—February 14—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway, or spur, on Harbor Quay, town of Goderich, Co. Huron, Ont., at mileage 111.8 on the C.P.R. Guelph and Goderich Subdivision.

21419—February 24—Amending Order No. 20817 by adding the following words after the words, "It is ordered that," in the first line of the operative part of Order, namely: "subject to the condition that the Applicant consent to accepting a new notice offering $600 instead of $1,200."

21420—February 27—Authorizing the C.L.O. & W. to construct bridge No. 88.0 aross the Trent River, Trenton, Ont.

21421—February 27—Authorizing the Esquimalt and Nanaimo Ry. to construct its railway across the railway of the Anderson Logging Co., near mileage 33 of the extension of the E. & N. Ry., from McBridge Junction to Courtenay; said crossing to be protected by an interlocking plant.

21422—February 26—Amending Order No. 21137 by striking out the words, "men appointed by the G.T.R." after the the word "operated" in the third paragraph of the operative part of the Order, and substituting therefor the words, "by the train crew of the G.T.R. Co."

21423—February 28—Authorizing the C.P.R. to use and operate bridges Nos. 15.69 and 103.7 on its line of railway.

21424—February 28—Authorizing the C.P.R. to construct, by means of grade crossings, the tracks of its Bassano Easterly Branch across road allowances between Sec. 6, Twp. 22, Rge. 3, W. 4 M., and Sec. 31, Twp. 21, Rge. 3, W. 4 M., at mileage 97.8, and between Secs. 28 and 29, Twp. 21, Rge. 4, W. 4 M., at mileage 92.8.

21425—February 27—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or spur in lane in Block 200, town of Swift Current, Sask., to serve premises of John J. Perrigo and Calgary Brewing Co., situate in Subdivision, Lots 7, 8 and 9, in said Block 200.

21426—February 27—Authorizing the C.P.R. to construct, maintain, and operate a branch line of railway, or spur from a point on existing spur in lane in Block 69, thence across Subdivision Lots 7, 8, 9, 10 and 11 of Block 69, Calgary, Alta., to and into premises of Crown Feed and Produce Co., situate in Subdiv. Lots 7, 8, 9, and 10 in said Block 69, on C.P.R. main line, Alta. Div.

21427—February 27—Rescinding Order No. 20407, in so far as it directs a crossing at the west boundary of M. W. Smith's farm.

21428—February 27—Amending Order No. 19546 by striking out paragraph 3 of the operative part of the Order and substituting therefor the following:—

> "3. That the normal position of signals on both lines be at 'danger,' except between the hours of 1 a.m. and 6 a.m., during which period the normal position of signals shall be at 'clear' for the Toronto, Hamilton and Buffalo Railway Company, and at 'danger' for the Applicant Company; and that in the movements of trains of the same or of a superior class over the said crossing, trains of the Toronto, Hamilton and Buffalo Railway Company have priority at all times."

21429—March 2—Extending until the 31st May, 1914, the time within which G.T.R. are to construct and complete siding to and into premises of the Harris Abattoir Co., in Lot 10, Con. 1, Twp. Barton, Hamilton, Ont.

21430—February 24—Approving agreement between Bell Telephone Co. and the Municipal Corporation of the Twp. of Waterloo, dated Feb. 7th, 1914.

21431—February 28—Ordering the G.T.R. to stop its train No. 69 on flag signal at Glanford Station, Ont.

21432—March 2—Amending Order 21310, by inserting between the word Section and the figure 6 the following figure and words, "5 and the Northeast Boundary of Section, in the recital and operative parts of the Order.

21433—March 2—Authorizing the C.P.R. to use and operate bridges Nos. 90.2, 60.6, 63.3 and 0.3 on its line of railway.

21434—March 3—Rescinding Order No. 21402, in so far as it suspends Sup. No. 40 to the C.P.R. Tariff C.R.C. No. E-2353; directing that Sup. No. 44 to the C.P.R. Tariff No. E-2353, be lawfully in effect from and including Feb. 25th, 1914.

21435—March 3—Authorizing the C.P.R. to construct road diversion in Section 3, Twp. 23, Rge. 28, W. 3 M., Sask.; and to construct the tracks of its Swift Current Northwesterly Branch Line across such diversion at mileage 101.07.

21436—March 3—Ordering the C.P.R. to appoint and maintain a station agent at Ralph, Sask.

21437—March 3—Authorizing the C.P.R. to construct, maintain and operate extension to trackage for the Crown Grain Co., Limited, Winnipeg, Man., from a point on existing spur of the C.P.R. in Block G, St. Boniface, Man., on the C.P.R. main line, Manitoba Division.

21438—March 3—Relieving for the present the G.T.R. from providing further protection at the crossing of Main St., just east of Thorndale Station, Ont.

21439—March 3—Granting leave, subject to terms and conditions contained in said by-laws, to the Hamilton St. Railway to cross with its tracks, at rail level, the tracks of the G.T.R. (Northern and Northwestern Div.), and the tracks of the Hamilton Radial Electric Ry. on Kenilworth Ave., in the Twp. of Barton, Co. Wentworth, Ont.

21440—March 3—Ordering the American Express Co. to put in a twenty-three (23) cent rate from Springfield to Hamilton, Ont.; said rate to become effective not later than April 3rd, 1914.

General Order No. 122—Rescinding General Order No. 116, dated December 24th, 1913.

21441—March 3—Establishing collection and delivery limits of the Express Companies in the city of Edmonton, Alta.; and rescinding Order No. 20972, dated Oct. 31st, 1913.

LONGITUDINAL RAILWAY OF CHILI

A DESCRIPTION OF THE BUILDING OF THE NORTHERN SECTION—A 450-MILE LINE THROUGH THE CHILIAN DESERT FOR PURPOSES OF PROTECTION AND DEFENCE.

By **E. H. DRURY, M. Can. Soc. C.E., M. Am. Soc. C.E.,**
Consulting Engineer, Ottawa, Ont.

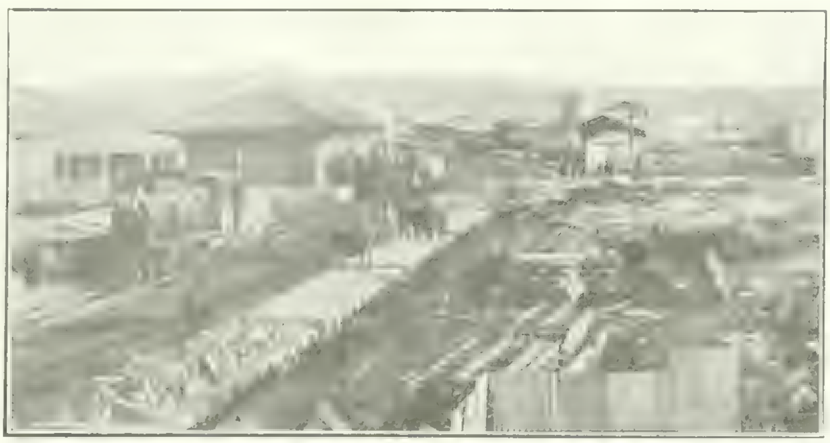
CHILI has long been the most powerful naval republic of any of the South American independencies. After the war of 1879, however, when Peru and Bolivia were despoiled of their territory by right of conquest, which included the vast nitrate beds of the Tarapaca Pampa, it was thought by the Chilian Government and politicians that it would be well to construct a longitudinal railway so that troops could be moved by land to protect their valuable acquisitions, if in the event of war the control of the sea was lost.

In the year 1888 the then Chilian Government, under the presidency of the late Don Jose M. Balmaceda, brought the issue into prominence by advertising the concession for the building of this railway, and among the contractors seeking the concession was the firm of Ross, Holt, Mann and Mackenzie, Sir Donald Mann and Mr. Holt going to Chili and entering into negotiations for the building of the road. But when everything was ready for the signatures of the contractors, the revolution of 1889 came into existence, and after fierce fighting at Santiago and Valpariso the Balmaceda Government was defeated and deposed, thus delaying the longitudinal railway enterprise for some years to come. It did not materialize again until it was carried into practical effect by the late President Don Pedro Montt, who, considering the railway essential to the welfare and development of the country, never rested until a contract was signed for the building of the north and south sections from Serano to Pintados, a distance of some 700 miles. The northern section was first to be signed and is dated 23rd April, 1910. This contract covers the ground from Pueblo Hundido (which is one of the inland stations of the Chanaral Railway) to Pintados, on the main line of the Iquique Nitrate Ry., a distance of 450 miles. This concession was originally granted to the Chilian Construction Co., Limited, who later transferred their rights to the Chilian Northern Ry. Company, the present holders, and who entered into a contract for the carrying out of the work with Messrs. Macdonald, Gibbs and Macdougall, Engineers and Contractors, New Broad Street, London, Eng.

A Cut Near Pueblo Hundido.

For the purpose of convenience in the construction of the line, this firm decided to divide the work into six sections, each section being connected by railway from the coast, thereby giving a route for the transportation of supplies and material to the work. The sections were as shown in Table I.

It is worthy of note that of all the railways enumerated in Table I. the only one which is of the same gauge as the longitudinal railway, viz., one metre (39.37 inches), is the state-owned Chanaral Ry., the others varying from 2 ft. 6 in. to 4 ft. 8½ in., which involves transshipment at the point of junction in order to reach the ports. The country through which the road was built being a desert, nothing was indigeneous to the soil. All material, supplies, plant, etc., was imported either from England, Canada, Germany or the United States. Chanaral [illegible] the



Catalina Station and Yard.

only port at which rolling stock could be landed from steamers, set up and taken direct to the work ready for service. At all other points, engines, cars, etc., were taken in piece-meal and erected at the different material yards established at the junction points by the firm.

Work was first started at El Toco in January, 1911, and the Baquedano section was commenced a week or two later, with the result that the first official train ran from Baquedano station to Toco station on the 16th September, 1911, thus forming an interior connecting link between the ports of Antofagasta and Tocopilla. The line between these points passes over the rich nitrate pampa of Tocopilla, from which industry the railway will derive the largest portion of its freight and passenger revenue.

Typical View of Country and Nature of Work.

The Aguas Blancas section was next attacked, and in rapid succession the Pintados, Catalina, and Pueblo Hundido followed. In July, 1913, the rails were joined from the north and south and by November, 1913, the whole of the line was completed and handed over to the original concessionaires. Thus in two years and ten

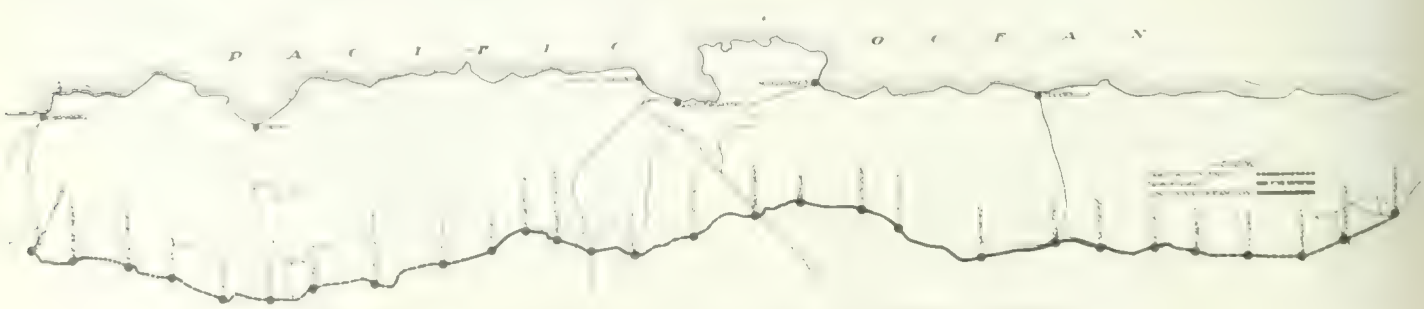
Pintados Yard and Station.

months the total distance of 450 miles of railway was graded, track laid, telegraph lines, tanks, stations, freight sheds, round-houses, work shops, machine shops, car sheds and turntables were erected; and all rolling stock necessary for the equipment of the road delivered and set up ready for operating. The rolling stock included sleepers, diners, 1st, 2nd and 3rd class passenger cars, flats, boxes, open boxes, cattle cars, powder vans, tank cars and 27 engines of different classes. This record for railway building in Chili is absolutely unprecedented.

Table I.

Pueblo Hundido (Junction with Chanaral Ry. northward to Altimira)	50 miles
Altimira northward to Catalina (Junction with Taltal Ry.)	44 "
Catalina northward to Aguas Blancas (Junction with Aguas Blancas Ry.)	81 "
Aguas Blancas northward to Baquedano (Junction with Antofagasta and Bolivia Ry.)	70 "
Baquedano northward to El Toco (Junction with Tocopilla Ry.)	98 "
El Toco northward to Pintados (Junction with Iquique Ry.)	107 "
Total	450 miles

The work was accepted by the Government in sections of 75 miles. Corresponding decrees were issued guaranteeing payment of interest and amortization on the value of these sections as provided by the contract. Based upon these decrees bonds have been successfully issued in London. The contract was to have been completed in April, 1914, and was therefore finished five



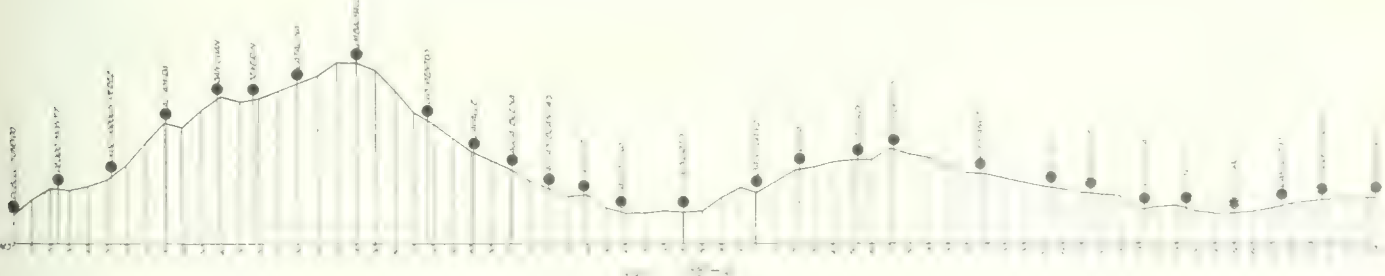
General Plan of Northern Section, Chilian Longitudinal Railway.

months before date of expiry. Thus by the completion of the Northern section the whole of the great Chilian nitrate districts are now connected by rail with Santiago, Valpariso and Port Montt, the total length of the system being 1,600 miles.

The northern section is built across the great Chilian desert on which for the whole distance of 450 miles one cannot find a blade of grass or a living insect. In fact, it is absolutely devoid of life. Darwin, in his travels, which included the Chilian desert, states: "It is the most perfect desert in the world."

In building the line, the water question was one of the most serious problems, but by hard work in drilling the contractors were eventually rewarded, and secured a good supply from wells at different points on the line. In some places it was found necessary to erect condensers as the only water obtainable was salt. These plants yielded a supply of 15,000 gallons per day, and gave excellent satisfaction. At some of the wells, owing to the hardness of the water it was necessary to erect softeners, the water first passing through chemicals then to the tank for engine supply. During construction water was often hauled 60 miles in order to supply the workmen doing the grading. The labor employed was native, and a better class of railroaders would be hard to find, from five to seven thousand being constantly employed.

Baquedano Yard, Showing Car and Engine Sheds.



Profile of Route of Northern Section.

As nothing grew in the country, all supplies of every sort and description were imported, the majority of the ties, telegraph poles and timber for stations, etc., were obtained in British Columbia, although a few ties, etc., came from Southern Chili. The stations were constructed with timber frame covered with corrugated iron; matched board partitions. This was the rule with all buildings except the main machine shops at Baquedano which were of steel frame covered with corrugated iron. Tanks and softeners were of steel, with steel frame on concrete foundations.

There was only one bridge on the whole line, this being at Quillagua, across the Loa River valley. As it never rains in the country there are no streams to cross.

As the sections were accepted by the Government, and the decree issued, the contractors were obliged to operate these accepted sections. Before the final acceptance of the whole line the contractors were operating 250 miles, on which a large traffic in the haulage of nitrate and supplies to the different nitrate plants along the line was developed. During an outbreak of yellow fever in the port of Tocopilla in the summer of 1912, the road was able to maintain the traffic between the ports of Tocopilla and Antofagasta by the interior connecting link, thus saving thousands of pounds in keeping the many nitrate plants in supplies, thereby avoiding their closing down during the epidemic. Up to this date all supplies had been shipped to Tocopilla by sea and then to the Pampa by the Tocopilla Railway. As the port was in quarantine during the epidemic, ships were not allowed to enter or leave.

The whole of the work was under the supervision of the Chief Government Engineer, Sr. Augusto Knudsen, who spared no pains to see that the work was well and properly done. The chief engineer for the concessionaires was Mr. W. B. Leane, A.M.I.C.E., with headquarters at Santiago. The headquarters of the contractors, Messrs. Macdonald, Gibbs and Macdougal, was in Antofagasta, the chief sea port of Northern Chili. Here they employed a large staff, the heads of the different departments being either English or Canadian. The whole work was under the direct control of the general manager. The partners, Messrs. Arthur C. Macdonald, a Nova Scotian by birth and a graduate of the Royal Military

College of Canada, and Edward T. N. Macdougal, are both well-known engineers and contractors in London and Chili. In the latter country they have carried a number of large and important works to a successful finish.

To more fully give a comprehensive idea of this undertaking, a map is given of the route showing connections with the coast ports, a grade profile showing altitudes which vary from 3,250 to 7,852 feet above the sea, and a number of photographs illustrative of the buildings, nature of work and country through which the railway passes.

INTERNATIONAL ENGINEERING CONGRESS, 1915

Rapid progress is being made in working out the final programme of papers for the International Engineering Congress to be held in San Francisco in 1915.

The first volume of the publication of the Congress will consist of a series of articles descriptive of the various technical features of the design and construction of the Panama Canal. The various topics which will be treated are noted in the following list:—

(1) Introductory Chapter.
(2) Dry Excavation for the Panama Canal.
(3) Dredging in the Panama Canal.
(4) Terminal Works, Dry Docks, and Wharves of the Panama Canal.
(4) Permanent Shops of the Panama Canal.
(6) Coaling Plants and Floating Cranes of the Panama Canal.
(7) Meteorology and Hydrology of the Panama Canal.
(8) Design of Locks, Dams, and Regulating Works of the Panama Canal.
(9) Method of Construction of the Locks, Dams, and Regulating Works in the Atlantic Division of the Panama Canal.
(10) Method of Construction of the Locks, Dams, and Regulating Works in the Pacific Division of the Panama Canal.
(11) Design of Lock Walls and Valves for the Panama Canal.
(12) Design of the Spillways on the Panama Canal.
(13) Gates of the Panama Canal Locks.
(14) Electrical and Mechanical Installations of the Panama Canal.
(15) Emergency Dams above Locks of Panama Canal.
(16) Municipal Engineering and Domestic Water Supply in the Canal Zone.
(17) Reconstruction of the Panama Railroad.
(18) Aids to Navigation of the Panama Canal.
(19) Geology of the Panama Canal Zone.
(20) The Working Force of the Panama Canal.
(21) Sanitation in the Panama Canal Zone.
(22) Purchase of Supplies for the Panama Canal.

Each of these topics will be treated by someone on the canal force who has been responsible for the design and construction described. The introductory chapter as well as the topic of Dry Excavation for the Panama Canal will be handled by Colonel Goethals himself.

The programme of papers for the various sections of the Congress is practically completed and notices of them will be published in the near future.

Buoys of reinforced concrete built for Kingston, Jamaica, weigh each about 5 tons, carry about one ton of ballast, and are said to cost a little less than half as much as steel buoys of the same size. The buoys are cylindrical in shape, with the bottom concaved to give protection to the mooring chain eye bolt. The sides have curved horizontal ribs, with bottom reinforced bars built up inside the shell, and waterproof cement on the outside and inside builds up [illegible]. The top is a solid slab, with reinforcement extended down the side. A temporary manhole serves for removing the interior centring and for convenience in lowering; but its cover is sealed in place when the work is finished. As water sometimes leaks [illegible] a pump hole with brass screw cap is provided.

COAL AND COKE PRODUCTION IN 1913.

THE coal mining industry in Canada in 1913 was marked by an increased production in the Maritime provinces of Nova Scotia and New Brunswick and in the Province of Alberta and a falling off in the provinces of Saskatchewan and British Columbia. In the latter province the decrease was entirely due to the continuance throughout the year of the labor strike in the mines on Vancouver Island. The lessened production in these two provinces was, however, more than offset by the increased output in Alberta and Nova Scotia so that the net result for the year was an increase of about 602,260 tons or 4.15 per cent.

The total production of marketable coal for the year comprising sales and shipments, colliery consumption and coal used in making coke, etc., was 15,115,089 short tons, valued at $36,250,311, as against 14,512,829 tons, valued at $36,019,044, in 1912. Nova Scotia shows an increase of 188,839 tons, or 2.4 per cent.; Alberta an increase of 903,800 tons, or 27.9 per cent.; Saskatchewan a decrease of 16,167 tons, or 7.1 per cent., and British Columbia a decrease of 494,548 tons, or 15.4 per cent. The figures for the Yukon represent for 1913 the production from the Tantalus field only, no record having as yet been received of the output below Dawson.

The production by provinces during the past three years, as given in a recent preliminary report by John McLeish, B.A., of the Division of Mineral Resources and Statistics, Canada, is shown in Table I.

Table I.—Production of Coal by Provinces.

Province.	Tons.	Value.
	—1911—	
Nova Scotia	7,004,420	$14,071,379
British Columbia	2,542,532	7,945,413
Alberta	1,511,036	3,979,264
Saskatchewan	206,779	347,248
New Brunswick	55,781	111,562
Yukon Territory	2,840	12,780
Total	11,323,388	$26,467,646
	—1912—	
Nova Scotia	7,783,888	$17,374,750
British Columbia	3,208,997	10,028,116
Alberta	3,240,577	8,113,525
Saskatchewan	225,342	368,135
New Brunswick	44,780	89,560
Yukon Territory	9,245	44,958
Total	14,512,829	$36,019,044
	—1913—	
Nova Scotia	7,972,727	$17,796,265
British Columbia	2,714,449	8,482,653
Alberta	4,144,377	9,462,836
Saskatchewan	209,175	347,685
New Brunswick	70,311	140,622
Yukon Territory	4,050	20,250
Total	15,115,089	$36,250,311

The exports of coal in 1913 were 1,562,020 tons, valued at $3,961,351, as compared with exports of 2,127,133 tons, valued at $5,821,593, in 1912, a falling off of 565,113 tons or over 26 per cent.

Imports of coal during the year included bituminous, round, and run of mine 10,743,473 tons, valued at $21,756,658; bituminous slack, 2,816,423 tons, valued at

$4,157,622; and anthracite, 4,642,057 tons, valued at $22,034,839; or a total of 18,201,953 tons, valued at $47,949,119.

The imports in 1912 were, bituminous, run of mine, 8,491,840 tons, valued at $16,846,727; bituminous slack, 1,915,993 tons, valued at $2,550,992, and anthracite, 4,184,017 tons, valued at $20,080,388, or a total of 14,595,810 tons, valued at $39,478,037.

Thus the increase of imports of coal in 1913 amounted to a total of 3,606,143 tons, or nearly 25 per cent. The increase in the imports of bituminous run of mine being 2,251,633 tons, or 26.5 per cent., increased imports of slack 900,430 tons or 47 per cent., increased imports of anthracite 458,040 tons or 11 per cent.

The apparent consumption of coal during the year was 31,685,456 tons as against a consumption of 26,934,800 tons in 1912. Of the consumption in 1913 about 42.8 per cent. was from Canadian mines and 57.2 per cent imported.

Coke.—The total output of oven coke during 1913 was 1,517,133 tons of 2,000 lbs., made from 2,147,913 tons of coal of which 1,598,912 tons were mined in Canada and 549,001 tons imported. The total quantity of coke sold or used by the producers during the year was 1,530,499 tons, valued at $5,547,694.

In 1912 the total output was 1,406,028 tons and the quantity sold or used by the producers 1,411,229, valued at $5,164,331.

The output by provinces in 1913 was: Nova Scotia, 920,526 tons; Ontario, 411,643 tons; Alberta, 65,104 tons, and British Columbia, 319,860 tons. That of Ontario was entirely from imported coal.

By-products from coke ovens recovered during the year included 10,608 tons ammonia sulphate; 8,371,600 gallons of tar and 3,353,731 thousand feet of gas, and the total value would approximate $866,150.

The ovens of the Acadia Coal Co. and Londonderry Iron and Mining Co. in Nova Scotia, the Atikokan Iron Co. in Ontario, the West Canadian Collieries and Leitch Collieries in Alberta and the Canadian Collieries, Limited, in British Columbia were idle throughout the year. At the end of the year there were 1,720 ovens in operation and 1,325 idle as follows: Nova Scotia, 572 active, 376 idle; Ontario, 110 active, 100 idle; Alberta, 134 active, 233 idle; British Columbia, 904 active, 426 idle.

The exports of coke during 1913 were 68,235 tons, valued at $308,410, and the imports 723,906 tons, valued at $2,180,830. In 1912 the exports were 57,744 tons, valued at $252,763 and the imports 628,174 tons, valued at $1,702,856.

Messrs. Ohrt and Ouistgoord, Danish engineers, have prepared plans and an estimate of cost for a submarine channel tunnel to connect Denmark and Sweden. According to the plans, the railway will be carried along the coast south from Copenhagen on an embankment, and the first part of the tunnel will be under the "Drodg," as that part of the Sound is called which lies between the mainland and the little island of Saltholm. The railway will run across the island above ground and then dip under the Sound again, till it reaches the west coast of the Swedish province of Schonen. The end of the tunnel will be at Limuhamm, which is a little to the south of Malmo. The entire length of the new railway will be about 30 miles, of which nearly 9 will be submarine tunnel. The greatest depth at which the tunnel will run will be about 100 feet, and it is estimated that the undertaking can be completed in 5 years at the cost of about $25,000,000. The tunnel will be worked by electricity, and will have to be driven through the same kind of stratum, grey chalk, as would the tunnel between England and France.

ORGANIZATION AND METHODS OF STREET CLEANING DEPARTMENTS.*

By **William H. Connell,**
Chief, Bureau of Highways and Street Cleaning, Philadelphia.

THE organization and methods of street cleaning is a comparatively new field for the engineer, and in this respect it differs from the other branches of highway engineering, such as the construction and repair of pavements, which have always been—at least in some localities—more or less under the jurisdiction of the engineer, even though only considered seriously by the engineering profession and the public within the last few years. The construction, maintenance and care of pavements is distinctly a highway engineering problem, and the cleaning of the pavements is a part of this work, and the highest point of efficiency will never be reached until it is so recognized.

We all agree that ease of operation is the most important factor to be considered in any organization, and this cannot be accomplished without centralizing the control of all the functions so closely related and interrelated with respect to the different branches of the work that there is bound to be an overlapping of jurisdiction and a certain amount of duplication of work and lost effort if under separate organizations. This is the case where highway and street cleaning work are under separate control, and it is for this, aside from many other reasons, that the cleaning of streets is properly a function of the organization having jurisdiction over the construction and maintenance of the highways. It is obvious, from a business and engineering point of view, that the logical way to handle both of these branches of highway work, in order to attain the greatest economy and efficiency, is through one organization, which would properly be the highway department. Unfortunately, most of the discussions and papers written relating to highway and street cleaning organizations have been confined to an outline of the methods of carrying on the work of existing organizations. A careful review of the ground covered in these articles forcibly suggests that the field cannot be economically and properly covered through separate departments, and that the inevitable solution is the one organization controlling all the branches of the work relating to the highways.

A proper highway engineering organization, composed of a personnel capable of controlling such work, would also be equipped to handle the collection and disposal of ashes, garbage and waste with far less additional expense than through a separate organization, and, as the ashes and rubbish should be collected previous to cleaning the streets, each cleaning and collection schedule bears a relation to the other, and, therefore, the line of least resistance would be to carry on both branches of the work through the one organization.

In Europe, street cleaning work is more generally under the supervision of the engineers than in this country, and it is usually under the control of a department having jurisdiction over the construction and maintenance of the pavements.

In Paris, the street cleaning authorities are charged with the construction and maintenance of streets and sidewalks, as well as with sweeping the streets and sidewalks, sprinkling roadways, collecting house refuse and

* Lecture delivered by Mr. William H. Connell before the Graduate Students in Highway Engineering at Columbia University on January 15th, 1914.

removing dirt, ice, and snow from the streets. The work is done by a branch of the Department of Public Works and is under engineering supervision.

In New York there is a street cleaning department having charge of the street cleaning, removal of snow, collection and disposal of ashes, garbage and rubbish, in the Boroughs of Manhattan, Bronx and Brooklyn. In each of these Boroughs there is a separate department having charge of the construction and maintenance of highways. In the Boroughs of Richmond and Queens the street cleaning, collection and disposal of ashes, garbage and rubbish come under the jurisdiction of the Department of Public Works, as does the construction and maintenance of highways.

In Chicago, the Bureau of Streets embraces street cleaning, collection of ashes, garbage and refuse, the removal of snow, and also street repairs, but not the construction of pavements.

The St. Louis Street Department embraces the construction and maintenance of streets, street cleaning, collection and disposal of ashes, garbage and refuse, and the removal of snow.

In Washington, the street department has jurisdiction over the construction and maintenance of streets, street cleaning, collection of ashes, garbage and refuse, and the removal of snow.

In Philadelphia, the Bureau of Highways has control over the construction and maintenance of streets, street cleaning, collection and disposal of ashes, garbage and refuse, and the removal of snow.

The above mentioned departments also have jurisdiction over other matters which are aside from the subject of this paper and will not be taken up, the object being, first, to point out the necessity for placing street cleaning work, including the removal of ashes, garbage and refuse, etc., under engineering supervision, and second, to combine this work with the general highway work. Of the cities mentioned the New York street cleaning organization—although second only from a point of efficiency to that of Washington—is founded on the wrong principle, inasmuch as it has not been an engineering department and is under separate control from the departments having jurisdiction over the construction and the maintenance of highways. The ideal organization for New York City would be somewhat along the following lines:—

The Bureau of Highways to have jurisdiction over the construction and maintenance of highways and street cleaning for the whole city. This would result in more uniform methods and more efficiency and economy in carrying on the work than exists under separate organizations, each working independently of the others. Of course, each Borough should have a voice in the management, probably through an Engineering Commission, somewhat on the order of the Board of Estimate, but the methods of carrying on both of these branches of highway work should be uniform in all of the Boroughs. New York has been selected to show the absence of engineering supervision in street cleaning and co-operation in both of these important branches of municipal work, simply because it is more in the public eye than any other city, and the generally accepted theory that one central body should control, so far as is possible, any one particular line of work, such as highways and street cleaning, has not been put into effect, even in this progressive municipality.

Cost of Cleaning Different Types of Pavements.—We cannot divorce the construction from the maintenance and care of the pavements, as the fundamental principles that should govern the selection and design of a pavement must necessarily take into consideration, amongst other things, the cost of the maintenance and its desirability from a sanitary point of view; and obviously in this connection the character and cost of street cleaning is a most important factor, as the welfare of the community must be considered, for dirty pavements are not only a great annoyance, but they spread disease, and no stone should be left unturned to combat this evil.

Aside from the financial, which is the first and most important consideration in any undertaking, the two basic principles that should govern the selection of a pavement are the traffic and sanitary requirements. Under these headings the gradient, first cost, cost of maintenance, noiselessness, social and local conditions, street cleaning, etc., may be grouped. In determining upon the proper pavement for the vast majority of streets in our municipalities, we should assume that the public health of the community demands that the pavements be kept clean. Therefore, the cost of cleaning during the life of the pavement is one of the primary considerations, and where the traffic conditions, aside from reasons due to gradient, might call for a stone block pavement, the cost of cleaning during its probable life might make it not only desirable but more economical to substitute an asphalt pavement on account of the lesser cost of cleaning. There is practically no definite data on this subject, but the following quotations from the report of a committee appointed in 1907 by the Mayor of New York City to investigate street cleaning methods, and from the Superintendents' Handbook on Cleansing, by Arthur May, Superintendent of Cleansing in the Metropolitan Borough of Finsbury, London, give a very good idea of the possibilities and value of collating reliable data along these lines for use in computing the cost of the maintenance and care of the pavements.

The following is quoted from the report of the New York Commission:—

"There is a very marked difference between the quantity of dust left upon the pavements of various kinds. Thus, if we call the average volume and weight collected from the sheet asphalt pavements 100, the relative quantities from other kinds of pavements were:—

	Volume.	Weight.
From sheet asphalt	100	100
From block asphalt	130	182
From wood block *	332	145
From granite block	1,081	912

After careful consideration of all the facts available, we estimate the average relative cost of cleaning, equally well, the various kinds of pavements in use in the city under similar conditions of repair as follows:—

Sheet asphalt pavement	100
Wood block pavement (new)	105
Asphalt block pavement........................	115
Brick pavement	120
Wood block pavement (old)	125
Medina block pavement	130
Granite block pavement	140
Belgian block pavement	150
Cobblestone pavement	3,000

On the assumption of 100 cleanings per year, it may be shown that the annual cost of cleaning equally well

* It should be said that the wood block pavement on which the examination was made is one of the oldest of its kind in the city, and its surface, being uneven, caught and held an uneven quantity of dust. Wood block pavement, when comparatively new, should compare favorably with asphalt block pavement in its freedom from dust-retaining qualities.

a mile of each of the pavements named over what it would be if sheet asphalt were substituted, would be as follows:

Wood block pavement (new)	$ 26.40
Asphalt block pavement (average condition)	79.20
Brick pavement	105.60
Wood block pavement (old)	132.60
Medina block pavement	158.40
Granite block pavement	211.20
Belgian block pavement	264.00
Cobblestone pavement	1,584.00

In speaking of the pavements of London, Mr. May says:—

"The four types of carriage-way pavings that are in general use are asphalt, wood, granite and other stone sets, and macadam. The order in which they are placed is, to all intents and purposes, the degree in which they lend themselves for cleansing, and, although the difference between the first three is not very great, there is no doubt that from a cleansing point of view, asphalt supercedes all others.

The following figures will give some idea of the relative cost per yard of cleansing the four kinds of road surfaces: Asphalt, 12 cents; wood, 76 cents; granite, 83 cents; macadam, $3.

"The above figures represent the cost per annum for the scavenging of one square yard of such roadway under equal conditions.

"It has been found that for every eight loads of slop removed from macadam roads, two loads are removed from granite sets, one and a half loads from wood paving, and half a load from asphalt."

If street cleaning had been more generally under the control of highway engineering organizations it is probable that we would be in possession of more definite data relating to this fixed charge in connection with the maintenance of our pavements.

Day Labor vs. Contract System.—There is one point in connection with street cleaning work that is generally agreed upon, both in this country and abroad, namely, the work involves so much detail, for which there are no definite units, that it can be more economically and better done by labor employed directly by the municipality than by the contract system. Philadelphia is the only one of the twenty-five largest municipalities in this country where the contract system is employed, and in this municipality the excessive inspection charge for the supervision of the work, aside from the fact that the work could be carried on more efficiently by day labor, is sufficient argument for municipal operation.

Uniforming Employees.—It also appears to be generally accepted that the street cleaning forces should be in uniform, and this is the case in the twenty-five largest municipalities in this country. In this respect it is singular that about nineteen years ago, when Col. Waring put the New York street cleaning force in uniform and established a more or less military organization, he was ridiculed by all the local newspapers and a number of others throughout the country. The wisdom of the step taken by Col. Waring, however, is generally appreciated to-day, as it is necessary to have a more or less military organization in connection with work of this character, and the uniforming of the force not only makes the men more conspicuous and permits the public to act as self-constituted inspectors, but raises the standard of the work and has the moral effect of increasing the efficiency through the pride the men take in the work.

Sources of Street Dirt.—Before going into the methods of street cleaning, it will be advisable to consider the origin and volume of street dirt, which is derived from a number of different sources, the principal ones of which may be summarized under the following headings:—

1. The excrement of animals.
2. Material lost by passing vehicles.
3. Dirt swept from sidewalks and thrown from buildings into the street.
4. Dirt from unpaved streets and alleys.
5. Falling leaves.
6. Building construction.
7. Soot and dust from the air.
8. Material originating from the wear of pavements.
9. Dirt due to scavengers picking over refuse placed on the street for collection.

To give an idea of the volume of street dirt collected, the Commissioner of Street Cleaning of New York in his report for 1912 states: "In the collection of the waste for this year we have handled 2,755,897 tons of ashes and street sweepings, 210,652 tons of rubbish, and 340,815 tons of garbage, a total of 3,307,364 tons. This accumulation, if placed in City Hall Park, would completely cover that area (8 acres) with a heap whose top would reach to a height 85 feet above the top of the new Municipal Building (or about 650 feet)."

Preventive Street Cleaning.—In considering some of the principal sources of street dirt, such as material lost by passing vehicles, dirt swept from sidewalks and thrown from buildings into the street, dirt from building construction, it is very evident that our streets could be made very much more sightly and the work of street cleaning carried on at a much less cost, if we had the proper kind of co-operation from the public, as the three principal causes of street dirt just mentioned could be entirely eliminated. This brings up one of the most important problems in connection with street cleaning, which is termed "Preventive Street Cleaning," and deals with the educational and publicity work being carried on to educate the people to use the same degree of care in connection with the streets that they do in their homes.

When Col. Waring was Street Commissioner of New York City he formed leagues of school children to teach their parents the importance of refraining from throwing refuse upon the pavements. At the time this was a novel way to reach the people in connection with preventive street cleaning work, but it is generally accepted to-day as one of the best means of carrying on work of this kind, and in Philadelphia a woman is employed in the Street Cleaning Department just for the purpose of securing this kind of co-operation from the school children, Boy Scouts, and civic organizations. The results from the educational campaign that is now being carried on in the different cities throughout the country will be more in evidence when the children of to-day have grown up, as street cleaning work, conducted on a scientific basis, is comparatively new, and a number of the older people do not show the interest that the growing citizens do in this or other branches of municipal work.

It is purely an educational campaign, but, like everything else, must be backed up by the law, and will often require a few arrests for offences, such as leaky wagons, throwing paper and store sweepings into the street, etc., to drive home the importanct of living up to the laws and ordinances regulating these matters. A good example of the kind of co-operation we want in this respect occurred in Philadelphia recently, when one of the owners of a large manufacturing establishment requested the

Department to help him keep clean the streets in the vicinity of his business by arresting any of his employees found throwing paper or sweepings into the streets, or violating any of the laws or ordinances designed to help keep the streets clean.

Waste Paper Cans or Baskets.—In many of the progressive cities in this country waste paper baskets or cans have been placed at different prominent locations throughout the city. In some cases these are paid for by the city, and in others by civic organizations interested in this work.

Scavengers.—One of the greatest sources of annoyance and unnecessary littering of the streets in many of our municipalities is due to scavengers, a class of people —men, women and children—who pick over the refuse placed on the curb for collection for rags, bottles, paper and other saleable products, and whenever they have an opportunity work in the same manner on some of the public dumps. In the course of their operations they always scatter a certain amount of ashes and dirt, etc., on the street. This trouble is also a source of annoyance in European cities, although they have it more generally under control. In Paris, for instance, there are twenty to thirty thousand scavengers operating in this way. Just before the house refuse is to be collected they go along the streets, spread a square of burlap or other cloth upon the sidewalk and tip the refuse can over on it and overhaul the contents, depositing in a bag the saleable products picked out. Thus they avoid littering the streets, and this is one of the conditions under which they are allowed to operate. The city authorities, however, have apparently been unable to rid the city of them, although they are not as objectionable as they might be, due to being under control.

Standard Methods.—In so far as street cleaning is concerned there is no such thing as standard methods in this country, or, if I am correctly informed, abroad. Each city in this country until only recently has been working independently of the other cities and without profiting by their experience. The report of the Chicago Bureau of Efficiency for 1913 states, in referring to data from other American cities in connection with a very exhaustive investigation carried on relating to street cleaning matters, that: "Inquiries directed to the larger cities of the country as to the methods and systems used in the cleaning and repair of streets and alleys and the collection of municipal wastes brought forward replies from twenty-five of the larger municipalities. The analysis of the information received showed the diversity of methods and conditions and a general lack of uniformity in maintaining uniform records and standards, and it was found impossible to use the same as a basis for comparison."

Referring to the work of the Chicago Bureau of Efficiency, which has been very commendable, both in the scope of the work and the character of report submitted, one cannot help but feel that what is really needed in this country, and particularly at this time—when all our leading cities are conducting investigations relating to all the branches of public works—is an association whose principal membership would consist of the cities and Public Works Departments throughout the country, organized for the purpose of collating data which would be of value to all municipalities, and would enable one to profit by the experience of others, and establish, in so far as the fundamental principles are concerned, standards for all classes of work, subject, however, to modification from year to year through investigations of committees appointed from the different cities and Public Works Departments for this purpose. This would enable all the cities to keep abreast of the times and would result in more uniform methods in all branches of public work throughout the United States. The Association for Standardizing Paving Specifications, which was conducted along these lines, and which accomplished more real work of general value to the country at large in the short period of its existence than any other society organized for similar purposes, has been recently discontinued. This was decidedly a step backward and is to be very much regretted, as this Association was founded on the correct principle, and its work was made a part of the work of the municipalities. It would appear to have been a wiser policy to have enlarged the scope of this Association to embrace all branches of public work.

Street Cleaning Methods Abroad.—In speaking of conditions abroad, it was recently said by an engineer, who has made an extensive study of street cleaning methods, that, taking into consideration the number of years they have been at it, the cost of labor and appropriations made, it might be expected European cities would be much further advanced than they are to-day. This is borne out by the following extracts from articles on street cleaning, from which it would appear they are not as far advanced as we would be led to suppose through comments of different citizens who have visited European and continental cities.

Commenting upon street cleaning in Paris, Soper, in his book on "Modern Methods of Street Cleaning," published in 1909, states: "Paris is universally conceded to be one of the cleanest and most beautiful cities. Many of its streets have been built in accordance with wise and comprehensive plans, a fact which has contributed substantially to its successful development."

Two years later the "Surveyor" for 1911 (an English publication) stated: "The following extract from an official report shows that Paris has somewhat fallen from its lofty heights, and, while the English towns have rapidly improved, the city of Paris has quite lost its supremacy:—

"The upkeep of the streets and roadways of Paris (the correspondent of the "Times" states) costs 600,000 pounds sterling ($3,000,000), and 5,000 men are employed in this branch of the municipal service. Although it is contended by French critics, Paris spends an enormous sum—which is far more considerable in proportion than the expenditure for this purpose in other great cities —the streets of the once renowned "Ville Lumiere" have fallen into a chronic state of deplorable neglect. The reporter of the Municipal Budget, who is unsparing in his condemnation of the filthiness of Paris, attributes the evil to want of organization on the part of the responsible services. Public works are executed at haphazard, without regard for promptness or uniformity. A single roadway is torn up time after time for one purpose or another, and no attempt at co-ordination is made. With regard to the actual cleaning of the streets, M. Dausett bitterly remarks that 'When all is said and done, the rain remains the great cleanser and scavenger of the Paris streets.' "

Referring to the same subject, "Cleansing Superintendent" for 1911, also an English publication, states:—

"It is certainly singular that the Paris Municipality has suffered matters in relation to the maintenance and cleaning of the public thoroughfares to go from bad to worse. They might usefully study the methods adopted in English cities, which are rarely excelled."

And the following quotation from the "Superintendents' Handbook," by Arthur May, likewise gives

some idea of the estimation of the English of French methods:—

"Much has been written and said of the extreme cleanliness of Paris and its modern methods, yet anyone with a critical eye cannot be impressed with the puny methods employed.

"Thirty years ago Paris was no doubt to the fore, but it has apparently been standing still for some years; consequently to-day it is very much behind many other continental cities, and has a lot of headway to make if it is to compete seriously with these and the large English towns. Even their own Chief Magistrate, in his report this year, seriously deprecates the inefficient means adopted to cleanse the city, and strongly urges for a responsible department to take control of this work. Channel and gutter swilling appears to be the important feature of street cleansing. The water is obtained from hydrants placed in the footways, and these emit the water on to the outer edge of the curb, so that when turned on it runs along the gutter in the direction of the gradient. Should the flow not be sufficient a dam is made by using heavy pieces of sacking, and the same process is applied should it be desired to cause the water to flow one hundred feet a minute, gathering up enroute dust and light articles. The operation is assisted by a man with a broom, who sweeps all refuse within reach into the flowing stream.

"In summer the roads are hand-sprinkled with a 2-inch rubber hose, and to those who have watched the operation there is no doubt that the men so employed are masters in the manipulation of this hose. Generally the refuse is washed into the sewers."

From these extracts it is evident that the English consider their methods par excellence. This, however, we have often heard disputed, the general consensus of opinion being that German cities are further advanced in this branch of municipal work, which might be implied from the following description from the cleansing method in Berlin by Mr. Arthur May:—

"The city of Berlin is undoubtedly one of the most advanced in methods of street cleaning, as is also the plant in use. Modern science and education have been brought to bear in a very marked degree upon the scavenging of the city. The streets are flushed regularly by water vans, and at present they have in use a machine which undoubtedly represents the highest success yet obtained in street cleansing appliances. The machine is electrically driven, and consists of a street watering van with a machine broom behind. The water is distributed at the front and sides of the vehicle, and the whole operation of machine sweeping and street watering is accomplished by one man in one act. The delivery of water is so controlled that pressure, obtained by compressed air, may be applied in its distribution; thus street swilling and brushing may be effectively carried on even during the busiest part of the day. Many continental cities have in use a new type of apparatus in the form of a watering cart, to which is attached a rotary squeegee, fashioned somewhat after a rotary machine broom. The effect of this combination is that a street may be washed and left practically dry afterwards, the apparatus being worked by one man only."

We must, however, refrain from relying too much on these statements if we are to judge from the following quotation from the "Superintendents' Handbook," by Arthur May, referring to the street cleaning in New York:—

"Wonders may be expected from this hustling city in its street cleansing operations, yet the only factor which strikes one from the official data is that the Chief Commissioner, who is the head of the Street Cleaning Department, appears to get a salary of about $7,500 a year, and in this respect New York is certainly a shade in advance of the English capital. This official, however, only holds office so long as the Mayor for the time being holds his.

"The streets are swept by hand, by order of the authorities, and the methods adopted are somewhat ancient. A short-handled broom, a scraper and a pan-carrier are the tools used. The can is like a barrel mounted on two wheels, being upright, with an open top.

"Length-sweeping is adopted, each man being allotted a length of street from 400 feet to a mile, according to the width, and he is expected to keep this section clean. The refuse made is placed in the receptacle, or can, at other times into bags, these in their turn being emptied into vans, which ultimately deposit their loads into barges. The whole of the work is done during the day time. No water can precede the sweepers, but flushing with a hose is practised somewhat extensively, as is also swilling by the water-can.

"The refuse is tipped upon low-lying land."

At the time this book was written, New York was advanced according to present-day standards in street cleaning, and there was apparently very little difference in the methods used in New York and foreign cities, which illustrates the danger of laying too much stress on the point of view of an individual in the absence of definite data.

(To be continued.)

A most favorable report was issued in February at Montreal by the Nova Scotia Steel and Coal Company for the year ending December 31, 1913. The net earnings amounted to $1,255,155.54, being an increase of about 25 per cent. over those of 1912, and being equal to 11.14 per cent. on the outstanding capital of $6,000,000. These earnings compare with $1,000,609.93 in the previous year, which were equal to 8.43 per cent. on the capital.

The progress made in the surveying of the province of British Columbia during 1913 has established a record, according to the report of the Surveyor-General, which is included in the annual report of the Minister of Lands, presented to the Legislature recently. One million acres of crown lands have been surveyed by the Government, and the greater part of this vast area has been subdivided into lots varying from 40 to 160 acres in extent; 400 miles of district boundaries have been run; explorations have been carried out in Cassiar and Peace River districts, and a commencement has been made on the de-limitation of the eastern boundary of the province in conjunction with the Governments of the Dominion and of the province of Alberta.

The recently published report of the Surveyor-General included in the annual report of the Minister of Lands shows that in British Columbia, in the matter of private surveys, the outstanding feature of the year is the quantity of timber lands surveyed. It is probable that when all returns are received it will be found that 1,500,000 acres of land held under special timber license have been surveyed, which equals the combined area surveyed in 1911 and 1912, and amounts to, practically, 30 per cent. of the timber land held under license and unsurveyed at the beginning of the year. On the other hand, the area of land surveyed privately is under 600,000 acres, or only about 50 per cent. of that surveyed in the preceding year, the shrinkage being due to the decrease in the area of unsurveyed land held under application to purchase. The area of mineral claims surveyed is well above the average. The area of surveyed coal licenses and leases in general is about the average. The area of land surveyed by the Government is practically double that of 1912, notwithstanding the fact that the expenditure of this year represents survey of land in all parts of the province, including the most difficult and dangerous sections.

SOME FEATURES OF HIGHWAY SURVEYING

A TREATISE DEALING WITH BOTH THE PRACTICAL AND THEORETICAL PHASES OF THE WORK—THIRD OF A SERIES OF ARTICLES ON THE SUBJECT.

By DANIEL J. HAUER
Consulting Engineer and Construction Economist.

IN a former article, highway engineering was described and commented upon up to the time of plotting the field notes.

Plotting Notes.—The plotting of the transit line and the surveyed area can be done on regular drawing paper, and afterwards a tracing made of it in ink to be sent to the chief engineer to have blue prints made from it. A better method than using ordinary drawing paper is to plot the alignment on profile paper. For this a sheet or roll of Plate A paper should be used, the upper half being used for the line and the lower half for the profile, or vice versa. Then, in the same horizontal scale, viz., 1 block, (or 2½ in.) = 100 ft., the line and profile run along in regular order and quick reference and comparison can be made of each. The vertical scale for the profile can be made 10 ft. to 2½ in. or one block. It is possible to shorten up this scale, but the plotting is not so easy and the paper thus saved will not equal the enhanced value of the drawing on the scale given.

Tracings of the plan and profile can be made on plain tracing linen, but better results can be obtained by using profile tracing linen, Plate A. From this tracing, blue prints can be made in the main office for office and field use. The importance of each party in the field plotting up the line and profile has already been stated, and if only this drawing work is done by the field party, a draughtsman is not needed. The making of all standard plans should be done in the office of the chief engineer.

The plotting of the alignment should be carried on each day, putting in on the plan all side measurements, the location of fences, property lines, where necessary, town and country lines, and showing the magnetic course of each. Culverts, bridges and waterways of all kinds should be shown, and the cross roads, private driveways, buildings and other features should be plotted. It may, at times, be necessary to locate telephone and telegraph poles, and the trolley poles for electric roads. It is sometimes necessary to move some of these poles, and so they should be properly located. Trolley tracks along a highway should always be located, and at times it is well to locate and plot on the map streams and other bodies of water that may be within several hundred feet of the highway.

Railway crossings of all kinds on the highway should be surveyed, and enough of the railroad line should be drawn to show how dangerous the crossing may be for rapidly moving vehicles. Changes of alignment of the highway should be made, if possible, to eliminate dangerous crossing. When money is available, and it is possible by legislative enactments to have the railroad share in the expense, grade crossings of the highway on the railroads should be eliminated, as under all conditions they are dangerous, but the elimination of such crossings is very expensive and few highway commissions have the necessary funds to do such work at present.

In plotting, each station on the sheet should be numbered in consecutive order. This is necessary as many men, such as foremen and supervisors, who are not accustomed to reading plans, will use the blue prints. The station numbers should be placed at the bottom of the plan, but all pluses should be noted in plain figures along the centre line.

At frequent intervals distances to the side of the road, to fence lines, and to buildings close to the highway should be shown. Care should be taken not to make the plan one mass of figures, but all important distances should be marked down. Too many plans lack essential measurements.

Buildings of different kinds should be shown by different symbols, and the various lines on the plan should likewise be shown by different kinds of drawn lines. A key of these symbols and lines given on one end of the plan allows each to be recognized without printing many words on the drawing.

The stations for the profile should be shown, but it is not necessary to reproduce the plus stations for these can be read from the plan. The elevations of the lines on the profile plate should be marked for every 10 ft. of elevation, and should be reproduced horizontally every 1,000 ft. The elevations should be marked at every change of the established grade together with the rate of the grade and whether plus or minus, on the grade line. The line of profile plotted should be the transit line. All culverts and bridges should be shown in a graphic manner, and with the elevations and plus stations marked on the profile.

The profile line is made with black ink, and the grade lines in red. It is sometimes a help in deciding on the many questions that arise, to plot the centre line and the two sides of the road. If these are only for office use and it is not considered necessary to have them show on the blue prints, these lines can be made in colors that will not readily blue print, as orange and yellow. If different colors cannot be used, and it is desired to have the lines show on the blue print, then various kinds of dotted lines can be used, a different line to show each profile.

The cross-sections taken can be plotted on the profile, or only special or typical sections need be plotted at convenient blank spaces. Outside of the typical sections, which should be on the profile, it is better to plot all the sections on regular cross-section paper, thus having a permanent record of the sections taken. In many cases these can afterwards be made useful, with replotting, in calculating the quantities of excavation and filling.

Whenever possible, there should be uniformity in all drawings and plans. For this reason, all standard plans showing cross-sections of road, and structures to be built, should be made in the office of the chief engineer and should be made the standard for all work to be done.

Trial Lines.—Trial lines or diversion of the road should be surveyed to make possible improvements in the alignment and gradient. As to the advisability of

such changes being made many considerations govern, besides the money available for such purposes. The money consideration is exceedingly important, for it is evident that if the amount of money is limited, but little of it can be expended for grading of new roads, if there are surfaces of old highways to be improved. However, if permanent improvements and betterments are to be made, to the end that good roads, admitting of economical hauling, are to be obtained, then it is manifestly wrong to improve stretches of roads that have poor and dangerous alignment and gradients that prevent fair loads being hauled.

Crooked highways with sharp curves are dangerous for automobiles, and more so for horse-drawn vehicles. A farmer with his wagon heavily loaded, meeting an automobile on a narrow road at a sharp turn, runs greater risk of being injured than does the party in the automobile. He, too, will be slower in getting out of the way. A steep hill means limitation of load. A team hauling a load 5 miles cannot carry any more than can be pulled up the steepest hill, even if it is a short one. This is an all-important fact to remember. Good roads not only mean good wearing surfaces, but also good grades, if we are to reduce the cost of hauling per ton-mile.

Thus, as a basis of any road improvement, sharp curves and heavy grades should be eliminated, so that money spent in the future for improving the surface will be upon a permanent highway. Money spent temporarily with a view of bettering the surface, only to change the line a few years afterwards is, to a great extent, money wasted; yet the amount of money appropriated for a certain highway may compel such makeshift work.

Even if a small amount of money, the importance of a close study of road changes is shown. Most country roads to be improved must be widened. This widening means extra grading, so that a decision as to relative costs of impróving the old line or adopting a new one must be reached only after a close study of alignment, profile and cross-sections.

This study must, to some extent, be made in the field, but only careful and close study of these features can be done from the plotting of these notes. This is another reason for the field party to plot up their notes. Then the work of running side lines or trail surveys can be done knowingly. For this work, the importance of both field and map study can hardly be overstated, even if a man has an exceptional "eye for country."

In making betterments, distances must be considered, but a larger load can be hauled a slightly greater distance at less cost than a smaller load over a steep hill. The distance travelled by a vehicle over a very steep hill is always more than the horizontal measurement. This may mean that a hill can be circled without a greater distance being travelled than in going over it.

In starting a trial line some point is selected on the transit line on the road and the new line deflected from it by turning an angle to the right, as frequently explained in making the survey. These lines are either numbered or lettered to distinguish them. A complete survey of the line is made, and all features of value in determining the cost of the work should be noted. Connection with the original transit line is made at some convenient point and again the full angle to the right is turned.

Levels are run over these trial lines and a profile made of each, and enough of the original line is plotted to show how the grade can be worked up.

Not only should crooked roads have trial lines run to better the line and grade, but every steep hill should have a line run around it. In the past too much money has been spent improving poorly located highways, instead of first bettering the location. Through well-populated improved country it is not always possible to better the alignment, but through unimproved country and open fields this feature of highway betterment should always be carefully considered. However, it should be remembered that long tangents are not necessary, for sweeping curves are not a detriment, but rather add to the beauty of a highway. Heavy gradients should always be avoided.

Traffic Records.—The cost of all highway improvements must be gauged, not only by the money available, but by the traffic that goes over the highway. Many laymen, who are road enthusiasts, advocate the building of first-class roads in all sections. These are much to be desired, but it is an unwise policy to expend large sums of money on by-roads, when we have so many heavy traffic roads to rebuild. The following of this practice is seen in the laws enacted for road betterment. In some sections, in order to obtain money from the provincial or state government to improve local roads, these highways must be made a certain width, cannot have greater than a specified grade, and must conform in other ways to a high standard. Through this kind of folly, the writer has seen roads that had less than a dozen vehicles pass over it in a day, made 24 ft. or more in width, when the old road was not more than 10 ft. wide. On the other hand, he has seen roads, built under the same laws, with excessive travel on them, to the point of being dangerous, built the same width.

Traffic records are essential to make knowing decisions as to highway improvements. Such records should show the number of vehicles moving over the road during the daylight period, these observations varying to suit the conditions as found. It is not enough to make such studies only as surveys are being made. Records should be kept for a longer period, and should show both summer and winter traffic. Sunday records should be kept, as many pleasure vehicles are out on that day when the weather is fair. The records should show the size and kind of vehicle, the load carried, the average length of trip and the extreme length of some trips, thus showing local and through travel.

With complete records of this character it is possible to decide upon the width of road needed, the kind of road surface to be built, and the need of bettering the line and grades. Many roads can be made from 14 to 18 ft. wide with a hard surface in the middle 10 ft. in width, and answer every need of the traffic. It is a manifest waste of money to go beyond this in a large number of cases.

Geology.—Geological conditions, as well as those called for by the traffic, must be considered in these matters. The cost of work will vary with the geology of the country. In making the survey, all geological features should be observed and recorded. The character of the soil, the location of rock and its character, should be noted for every station. The quarries, sand and gravel pits, and clay banks along the highway should all be located and shown on the plan. This should be done also on the trial lines. Frequently a road is expensive to maintain, due to the character of the soil, when a parallel line within a short distance can be kept up at half the cost. Likewise, it is expensive to cut down hills, with large boulders out-cropping, or ledge rock, in order to improve grades. To widen many roads

in their present location, means to get into rock and rough ground, that the original locaters avoided with a narrow road.

Adopting New Lines.—With surveys completed, trial lines run, traffic and geological records made, and the amount of available money known, the engineer and highway official are ready to decide upon the line to be improved. To obtain all of this information may have cost some money, but it is an expenditure well justified and one that will save a much greater sum in the end. This, though, is at variance with the practice of many engineers and highway officials, who first decide upon the line to be improved and then have surveys to find out what work is to be done. Such surveys are needed, but the other records and considerations do not enter into the problem; yet they too are obtained, and boasted of by those in authority, although it is money wasted, as far as any good obtained from them is concerned. This practice is only to be condemned.

It is not possible to give any rules for deciding upon alignment and grades. The information obtained from the surveys and records mentioned must govern the selection, based upon sound judgment gained from experience. The engineer should be the one to make the final decision, but even a layman, with such information before him, can assist in deciding upon the proper line.

Laying Down Grades.—Although the alignment of a road decidedly affects the cost of highway construction, yet the establishing of grades is a more potent factor. A few tenths in elevation does not greatly affect vehicle traffic, yet if they mean the blasting out of rock by hand methods, an excessive cost is entailed.

The limit of gradients should be set by the vehicle traffic records. Generally 5% should be the maximum grade, as with such fair loads can be carried and rapid-moving vehicles have no trouble in climbing. But, if the traffic is light and such grades mean excessive cutting, then gradients up to 8% may be used.

The establishing of new grades alone may mean the changing of a line. Thus it may be cheaper to build a new road on easy grades than to cut down hills to the maximum grades.

Care must also be taken not to make grades too decided and long, as is done in railroad construction. Many engineers, experienced in railroad work, entering the highway field, make this mistake. There is no need in highways of long straight lines with grades causing deep cuts and high fills. These cuts mar the beauty of the country, obstruct the traveller's view, and mean a great cost in building and maintaining the road. High fills are dangerous, must have guards on each side to prevent accident, and are washed badly by summer showers or in flood periods. As with the alignment, the grades can be sweeping curves, so as to keep down the cost of construction, yet keeping in view the traffic to be carried. It is even possible to have short raising grades to go over various obstacles, as small knolls, bridges and railroads, care being exercised in not making them too steep and short and with the proper view for approaching vehicles. This prevents long, high embankments.

In establishing grades care must likewise be exercised in preventing the top of a grade from being so sharp that vehicles cannot see one another in approaching. All changes of grade should be made with vertical curves. The value of proper drainage can hardly be overestimated, but drainage to some extent is dependent upon the laying down of proper grades.

Deciding Upon Improvements.—The next question to be considered is that of how improvements are to be made, the width of road, the surface to be laid and the method of doing the work.

One prevailing idea is to do as many miles of work as possible with a given sum of money, expending some in each town or road district, that is, not to build a good road of some particular type, but rather to repair the roads as they may be at present. This means to do little work that is permanent, giving only passable roads for a season and possibly taking out a few bad curves and grades. It is a wasteful procedure and defeats the object of any legislative act to improve roads. Nevertheless, it is a popular method, as it means the expending of some money in each community, the so-called "pork barrel" distribution of public funds. The roads on the North American continent need rebuilding and not just repairing as a bit of political jobbery to curry favor with the unthinking classes.

The second method is to decide upon the kind of road to be built in a given section, the width, alignment, grade and surface to suit the traffic and local conditions, taking into consideration the money available. Then build the very best road possible under these governing factors. Thus, wherever work is done good highways are obtained, and if properly maintained, a permanent improvement is made, the taxpayers receive full value for their money, and with the benefits that accrue to the community from the use of such roads, there is a demand for a greater mileage and the public gladly acquiesces in making financial arrangements for additional work. This scheme should be advocated by all those desiring to have good roads.

Even with this method, short sections of roads are built in different districts. This is a political aspect of the subject and, unfortunately, it is necessary to follow out this system to some extent, as otherwise many communities, feeling they are being slighted and deriving no direct benefit from the expenditure of the road money, will vote against future bond issues, although by so doing they are cutting themselves off from enjoying the benefits of future improvements.

As far as possible, long stretches of roads should be improved at a time. Economic reasons make this imperative. Small contracts mean high prices. The cost of plant for road construction is high, much higher than for many other classes of work, and so the plant charge against a small job is much higher than for a larger undertaking. As the road building season is short, especially in the north, a job should be large enough to keep the forces and plant busy for a season, without being moved. All of these and many other considerations will mean more road built for the same money.

Contract Work.—There are two methods of having the construction done on roads. One is by day labor forces, that is by men, machines and teams employed by the day, working under the directions of the road engineer and his assistants. The other is to let the work by contract, the contractor doing the work under the supervision of the engineer.

The first is generally an extravagant method; men do not work their best under such conditions, nor is the character of the work done of the best. Under the contract system the contractor is responsible; he requires men to work well, he is made to live up to the specifications and contract, and the unit cost of the work is known as soon as the contract is let.

The contract system can also be used for highway maintenance. Specifications can be drawn up for such work and it can be paid for by various units, according to the character of the work. Space will not permit of a further discussion of this subject, but the better method is to build and maintain highways by contract.

Road Surfaces.—A decade or two ago there were only a few kinds of road surfaces in use, while to-day they are numerous. Many of the patented surfaces and some of the newer types have not been in use long enough to definitely learn their advantages and disadvantages, but every road engineer should make a close study of all the different types. In some cases chemists must be consulted.

In deciding upon the surface to be used, the governing factors must be the amount and character of the traffic and the materials that can be obtained for the money available. This may necessitate the use of local materials, and the engineer should know enough about the various kinds of surfaces to select the best. Too frequently poor results are obtained from a lack of knowledge of this part of highway engineering. Only recently the writer saw a young engineer stop the use of beach gravel on a road, because of a lack of binding qualities of the gravel, and compel the use of a rotten rock from a pasture, which was ground up into mud within 6 months. Had he had some of this rock mixed with the beach gravel, and a small per cent. of suitable clay, he would have had a fairly good wearing surface, and the money would not have been wasted. This, too, would have cut down the cost of maintenance for some years to come. In deciding upon all surfaces, the ease and cost of maintenance should be considered as well as the adaptability of that particular kind of surface. Then, too, the cost of some materials may seem prohibitive, but this may be offset by the low cost of maintenance.

Locating the Road.—After all of the foregoing matters are decided the proper location of the new centre line is made. This location should be laid out on the ground. To do so, a new transit line is run, in the manner previously described in making the survey. Where the line has not been changed the same transit points and reference hubs can be used. This new line should be well referenced, and the stakes marked "L" showing that it is the located line. Then, new levels should be run over this transit line. The side levels are not necessary. From these levels a new profile is made, and then the work can be cross-sectioned.

All cross-sections should be calculated and payment for the work made on them alone. A standard section of the road should be made, and this should be followed in carying on the work.

Drainage.—Too much attention cannot be paid to the drainage of highways. Water is a sure detriment to all road materials. Roads should have ample subdrainage as well as surface drainage. Ample drainage should also be provided to prevent water from going onto road surface. It is easier to do this than to drain off the water after it has gone upon the highway.

Ample waterways, made of the most permanent materials, should be provided under the highways. To-day, in both Canada and the United States, millions of dollars are being wasted in maintaining flimsy, out-of-date culverts and bridges on highways. It is evident that if these could all be replaced with permanent structures, the money that is being spent each year for maintenance could be expended on the road surfaces.

RAILWAY TUNNELLING.

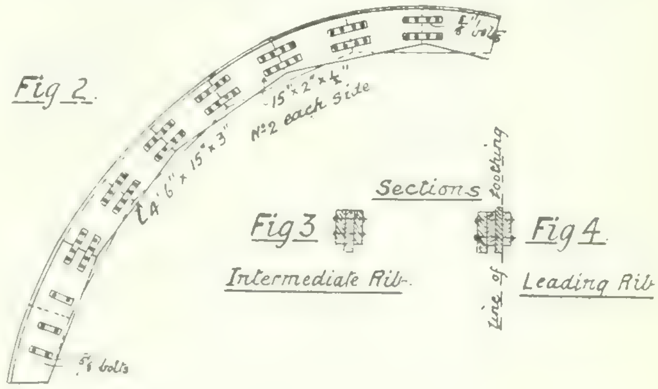
(PART II.)*

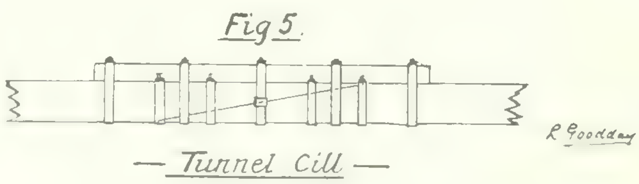
By Leonard Goodday, C.E., M.E.,
Late of the British Admiralty.

THE cost of driving a heading of the size outlined in Part I. of this article (January 15th issue) can be estimated only approximately, as it varies with the nature of the ground. In good shale, and where water does not prove a serious obstacle, conditions are most favorable to economical construction.

To arrive at an approximation of the cost per yard one must include excavation, timbering and supplies, operating expenses, percentage for engineering and contingencies, etc.

If the head-tree be 10 in. and side trees 8 in. in diam., with poling all around the excavation, per yard forward will be 10 ft. 7 in. x 8 ft. 6 in. x 3 ft. = 10 cu. ft. This may be let piecework, lineal, to include timber setting, but not to include pumping, power for hoist, or foremen and timekeepers.





A head-tree, 10 ft. x 10 in. diam.; 2 side-trees, 8 ft. x 8 in. diam.; 2 hard-wood foot blocks; and about 110 ft. B.M. of poling boards, constitutes the required timber per lineal yard of tunnel. Poling boards of 1½ in. thickness might at first appear unnecessary. It should be remembered, however, that some of them will probably remain in place until the tunnel is almost completed, subjected to dampness and rot, which soon impair their strength.

From the shafts sunk at either end of the tunnel, a heading may be driven back through the cuttings leading up to the tunnel's mouth until it reaches the face at which the cutting excavators are working. "Shoot-holes" can then be driven upwards from the roof of the heading to the surface of the ground; strong trapdoors are then fixed in the bottom of each hole at the level of the heading roof and opening downwards. Tip-wagons can be run under the holes, the doors opened, and the earth shovelled down from the top. In good ground, indeed, in almost any ground, 2 men at the hole will do as much as 4 filling in the ordinary way.

*Part I. appeared in Jan. 15th, 1914, issue.

This method does not work so well in a wet, or rock cutting, as the water naturally drains into the wagon, and by the time the latter has got to the tip-head, its contents are slurry; another drawback is that rock falling down the holes breaks the doors and wagons.

If the slope of the ground is about 1 to 1, the distance between these shoot-holes will be twice the depth of the cutting at these points. With 5 shafts, there will be 2 working faces at the cutting headings, or 10 in all. If the work is to proceed rapidly, 20 gangs will be required, including day and night shifts; so that for a gang of 2 miners and 4 laborers, 40 miners and 80 laborers will be the total strength. A boy for every 2 gangs, for fetching tools, etc.; a hanger-on at the bottom of each shaft to attend to skips and ring the signal-bell; and on the bank at least 2 banksmen for landing and tipping the skips would make up the staff.

As the heading progresses, light rails of about 15 or 20 lbs. per yd. are laid with a gauge of 2 ft. 6 in., on which small trollies operate, similar to those required on the bank. On these are carried the skips, each of which has a capacity of about 1/3 cu. yds. If it is intended to get tip-wagons into the heading when it is driven through, it may be as well to at once lay the temporary wagon road, and on it to place larger trollies, similar to those used by sectionmen. These will carry 3 or 4 skips each trip. To draw these a pony will be required, which can easily be stabled in a recess made in the heading.

The shafts in the tunnel under consideration are about 440 yds. apart, giving 220 yds. of heading to be driven from each face. At 1 yd. per shift for progress, this gives nearly 4 months as the time required to join the headings. Before this is finished, the mining and lining can be commenced from the shafts, the engineer having satisfied himself that the lines are correct, but it is wiser to commence a "break-up" when the heading is through, at least between any 2 shafts. A break is generally made midway between 2 shafts, and, consequently, at or about the point where the headings from the shafts meet.

When the headings are through, the engineer must give working centres again. He will be able to judge pretty well how correct his first lines were by the way the headings have met. Let one wire down each shaft and with the transit work the centre line in from the cutting outside. Run a trial line through the tunnel, leaving points as this work proceeds, and checking on the wire at each shaft. This trial line requires going over 2 or 3 times, as it is seldom correct the first time. When correct, it is necessary to fill up with permanent points between those left on the trial line, and to take notes of the position of each point, so as to be able to recognize them. Mischievous and discharged men, etc., have been known to move these points for spite or through ignorance. Establish plainly marked Level B.M.'s all along the heading at Rail Level.

When driving these headings water may be tapped, which must be conducted to the sumps under the shafts, so that it may be drawn off at certain intervals. A large barrel, holding 40 or 50 gals. and called a "landing barrel," is required for drawing this water up the shaft. Unless water enters in large quantities, this will serve all through the work. Otherwise a steam pump will best get rid of it. The former outfit must be complete in every way, with the trunnions on which it turns below its centre of gravity, so that when the catch is released it will tip easily and without disconnecting it from the winding-rope. Over 2,000 gals. per hr. can be raised by this means.

The contractors should see to the provision of a large supply of strong larch forbars for supporting the mined length, poling boards, brick, etc.

With respect to brickwork, if brick is used, an ordinary tunnel for a double line, without an invert, with walls and arch 2¼ ft. thick, and of the dimensions shown on the figure, will contain 17¼ cu. yds. of brickwork per yd. of length. If each length turned is 5 yds. long, this amounts to 86¼ cu. yds. If 350 bricks, 9 x 4½ x 3, are reckoned per cu. yd., a length will then require 30,000 bricks, and with 5 shafts, in 2 of which one length each per 10 days is to be turned (work only progressing in one direction from them), and 3 shafts, 2 lengths each per 10 days, one in each direction, are to be turned, there will have to be provided sufficient for 8 lengths in the course of each 10 days, or 240,000 bricks—a quantity hardly obtainable in most localities. Even if available, there might not be adequate means of transportation. Supposing the locality to be surrounded with brick works and the average distance to be 1 mile, a horse would make 5 journeys per day and bring 300 bricks per journey, or 1,500 per day. As 240,000 are wanted in order to keep up the supply, 16 horses and carts and 2 extra horses and carts for continual work would thus be needed. Besides these 18 horses there are all the others required for general work. An alternative worthy of first consideration, if the facilities for the operation are available, is the manufacture of brick at the site.

The section of the tunnel and thickness of lining having been decided upon, 26 ft. clear between the walls is the minimum for a double line. This width will depend upon the type of car and locomotive which the cross-section was designed to allow. It must be remembered that when a tunnel is on the curve, the cant of the outer rails causes the corners of the car to project. Therefore, keeping the same total width, the wall on the inside of the curve should be a few inches farther from the centre line than that on the outside. The centre line is still the centre line, between the rails, but is not that of the tunnel. This little difference can easily be adjusted when the curve enters the straight again.

We have supposed 5 shafts, 3 of which have 2 faces, one working each way, the other two shafts having one face each. Between each two shafts, a breakup is to be formed, which gives another 2 faces to each breakup. There will be 4 breakups in this case, and, consequently, 8 faces. Thus there are 8 faces due to 5 shafts, and 8 more due to the breakups, or 16 in all. In an organized tunnel, a length will be mined in 8 of these faces, and the bricklayers will at the same time be lining the 8 others.

For supporting the arch of a 5 yd. length, at least 3 ribs are required, 2 of them called intermediate, the other, "leading." A the ribs should always be left standing in 1 length until the next at the same face is keyed, it follows that 4 intermediates and 2 leadings are required per face, giving 96 ribs in all. These must be ready, with a few to spare for breakages, when the brickwork is commenced. Fig. 6 shows the curve of the arch beginning at about 6 ft. above rails, it being the real springing point of the arch. A scaffold is needed for this work, and it is advisable also to lay the finishing courses of the walls from this scaffold. Generally, centres are set at about 9 ft. above rails, and which point is called the springing.

The ribs should be built on a good, level platform, on which the soffit line, full size, is accurately described, with 2½ in. allowed below it for lagging. The tunnel being a heavy one, the ribs must be of well-seasoned ash or elm, and built up of pieces called sweeps; each one being

4½ ft. long, 1¼ ft. deep and 3 in. thick; for an intermediate rib 3 thicknesses of sweep, or 9 in., will be sufficient. One edge of each must be neatly adzed to the soffit line; keeping the full depth of the sweep at the middle. Fasten all together at every joint with 4 iron plates about 15 in. x 2 in. x ½ in., bolted completely through with No. 4 ⅝ in. bolts, having all bolt heads on the same side, as by keeping the heads all on one side, the rib can be more easily dragged about on the tunnel scaffold.

A leading rib is constructed in the same way, but with 4 thicknesses or layers of sweeps, one of the 2 inside layers projecting 2½ in. above the others, or equal to the thickness of a lagging. This rib is set at the leading end of the brickwork to be built, and remains in place. When the arch of the next length is ready for turning, the laggings find a bearing point on this rib on the other side of the rim. It also keeps them from slipping. Figs. 2, 3 and 4 show an elevation and sections of a rib.

support but that of the centres. The pressure must be very slight to allow such a condition.

When the ground is heavy and pressure great, the arch and length cannot be left without support, and the contractor cannot afford to leave bars bricked in above the brickwork in every length. Drawing-bars are introduced, bars so placed that the arch can be keyed in under before they are drawn out endways into the next length to be mined and used again.

The crown, i.e., the top bar, and 2 others on each side of it, 5 in all, form a set of drawing-bars. Those on each side the crown bar are called "third bars," because when in place, there are 3 bars in; the next 2 are called fifth bars, next 2 seventh, etc. The crown, third and fifth are all of a size, and, in a 5 yd. length, must be 21 ft. long at least. In heavy ground they should be not less than 16 in. diam. at the small end. They must be straight, free from knots, and should taper uniformly.

All the bars carrying the roof are supported upon a top sill, placed about 9½ ft. from the underside of the

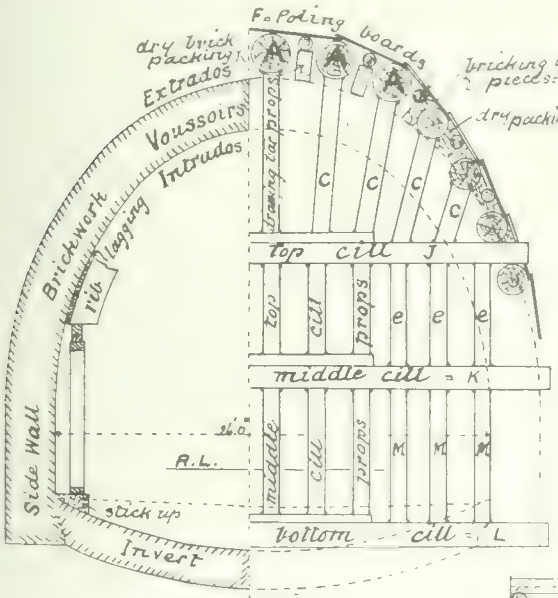


Fig 6.

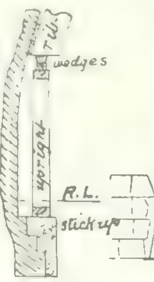

Fig 8
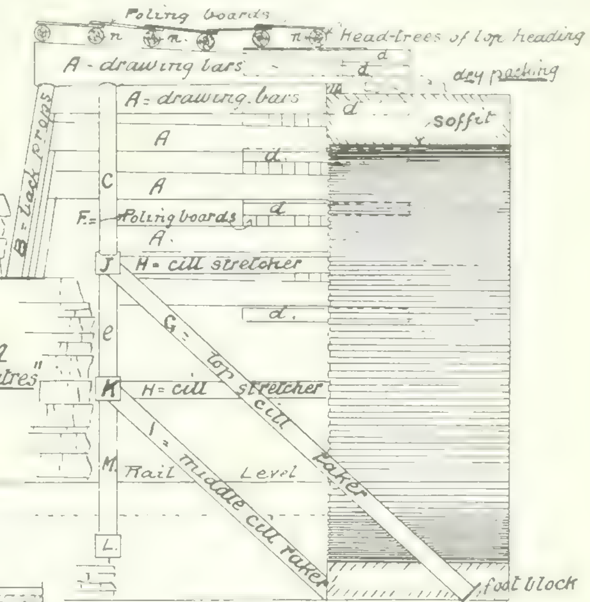
Timber framing Supporting "Centres"

— Plan of Fig 8 —



— Fig 7 —

Mining and Timbering.—The excavating and building-in of a tunnel is done in lengths, one length being mined and lined completely before much work is done in the next.

The extent of a length is determined by the probable weight which must be supported on the bars until the brickwork can be placed; also upon the size and quality of the timber procurable for bars. A length is seldom more than 6 yds., and is sometimes reduced to 3 yds. In a light tunnel all bars carrying the roof can be taken out as the brickwork is built up to them. The ground is excavated and mined as nearly as can be to the exact shape of the extrados of the lining. Therefore, the back of the bars supporting the ground is just even with the back of the lining, excepting 5 or 6 of them at or near the crown of the arch, which are kept up a few inches to compensate for settlement and sag. When the walls are built and the arch is under construction the bars are removed one by one as the work proceeds until the arch is keyed. It will be obvious that when the arch is within about 4 ft., measuring transversely, of completion, the crown, or top bar, must be taken out, and that the ground and incomplete arch are thus left without any

crown bar, and stretching horizontally across the tunnel at that level, just at the leading end of the brick work to be built. This top sill should be 13 in. square and 27 ft. long. (See Fig. 5.) The roof bars are all propped from it, and it is again supported, by props from another or middle sill, which should be yet stronger and 33 ft. long. The top sill cannot be put in place until the ground is excavated down to its position, and the ground cannot be mined without support from bars. The bars, in their turn, must be temporarily supported until the top sill is in place, so they must be long enough to allow of their being propped off firm ground, ahead of the length under construction. The roof bars should be 21 ft. in length.

The best timber for bars is larch. They should not be stripped of the bark as the timber then becomes slippery in damp places, and difficult to handle. They should be neatly scarfed for 5 ft. to make a sill. The top and bottom of the scarf should be faced with an iron plate about 6 in. x 4 in. x 1¼ in., and the 2 plates bolted together through the sill and enclosed by 4 iron glands. On the top of the scarf is placed a timber saddle the full width of the baulk, 6 in. x 9½ in., the whole

being secured by 5 additional glands, made out of 2½ in. x ½ in. flat bar.

The section of timber to be encircled by these glands is 13 in. x 13 in. for the sill proper, and a 13 in. x 6 in. saddle, making 13 in. wide x 19 in. high. The gland is made in 2 parts, one formed into 3 sides, to take the bottom and the 2 sides of the sill and saddle. On the ends of the 2 sides which are made to project beyond the 19 in. required, are formed good screws with nuts. The top side of the gland is then made separately, and long enough to provide for a hole in each end to fit over the screwed ends of the other piece, and the nuts screwed tightly down. The sill must be scarfed as it has to be longer than the width of the tunnel. As a sill should serve all through the work and will be taken to pieces many times, it should be well made. (See Fig. 5).

The first side length, next the shaft, let us suppose to be in and lined; this operation being similar to the following, except that sills must be used at both ends of it. But if bad ground has been encountered in sinking the shaft it will be safer to brick the crown, and third bars in the first side length, and not attempt to draw them, for fear of settlement. The fifth bars in this case must be "taking out" bars. The shaft length should not be taken out and lined until the shaft work is finished.

It has been decided to line the tunnel with 2½ ft. of brickwork. The lengths, to be got out one by one, shall be 5 yds. To support this length, 5 drawing bars shall be used, each 2 ft. diam. at the thick end. The drop shall be 1½ ft., i.e., the small end being borne upon the end of the brickwork of the last length, and the other end being set at a higher level by 1½ ft. to allow for sagging, settlement and possible breakage.

The first operation for the second side length is to drive a top heading 21 or 22 ft. long (enough to receive the crown bar) and high enough for a man to stand in it. It should be wide enough to take the thick end of the bar, say, 3 ft. in the clear under the head-tree. The distance apart of the bars is generally about 1½ ft., so that to take 2 bars, 2 ft. in diam. and 1½ ft. apart, the heading must be 6 ft. wide under the head-tree, and between side-trees. In very heavy ground 2 crown bars are sometimes used, as they together give a greater bearing for the head-trees, and support it better when the side bars are put in, or taken out. The heading must be supported by settings of head and side-trees about 1 yd. apart, and strong enough to bear the weight for 10 days or so. The heading should be poled all round.

The crown bar must be got into this heading by means of a crab and tackle.

As the top sill (Fig. 7) will be placed at about 6 ft. below the soffit of the arch, the ground at the far end of the top heading should be excavated across the heading down to a little below this level. In the bottom of this, foot blocks should be placed, on which will stand the long back props, supporting the bars until the top sill is in position. These back props should be 10 to 12 in. diam. and up to 9½ ft. long. Their length varies, of course. All props should be "collared," i.e., on two opposite sides at the top end cut off about 1 in. and run out about 9 in. down the prop; and then hollow out the top of the prop to receive the round side of the bar, which will give a good bearing surface, and prevent the outside from splitting. The props should be set with a sprag.

The crown bar being in and back propped, the next necessity is to get in the third bars, but as they must follow the curve of the arch, they are not quite so high above rail level as the crown bar. Widening out for these bars can be commenced by removing the side-trees of the heading, and the poling boards, and then excavating from the sides. When the third bars are in, short stretchers must be put in between the bars spaced about 5 ft., strutting one bar against the other, so as to distribute the pressure. Dog-headed spikes, or brobs, must be driven into the bar round the head of all props, four to a prop, to prevent slipping. When this excavation is done, poling boards must be placed transversely to the bar. The proper way, when the face of the excavation is straight, is to insert the board above the last bar put in, and hammer it into place; but as the excavation here is curved, it is sufficient if the ground be removed from behind the bar on the underside, and the board hammered upwards, until held by the bar.

The fifth of the set of drawing bars is now put into position. They hold the lower ends of the poling boards, and must be back-propped similarly to the others.

With an occasional helping hand, 2 miners and 3 laborers will get the crown and third bars into place when driving the top heading. As space widens out, and the fifth bars are got in, another miner and 2 laborers can be added. When the seventh bars are in there will be room for the whole gang, consisting of a gang boss, who must work as a miner, 3 miners, and nine laborers.

The fifth bars being in, spaced with 1½ ft. drop at their leading end, in placing the seventh bars. The extra size of mined section due to this drop allowance must be begun to be worked out, and the bars below the fifth brought gradually nearer in to the line of the extrados of the brickwork, until at a few feet below the level of the top sill, the line of the back of the brickwork is regained. The set of drawing bars occupy about 15 ft. of the circumference of the mined section, and in a 5-yd. length there are consequently 15 ft. x 15 ft. x 1 in. = 225 cu. ft., or about 8½ cu. yds. excess of mining over and above the net section of the brickwork owing to the allowance necessary for drop, before this is worked out, and the net dimensions of the bricked section regained.

No drawing bars would be required with a light tunnel, and this excess would be prevented. The seventh bars can be smaller than the drawing bars in length and diameter, as they are not under strain so long. They must, of course, be longer than the actual length to be lined, as they require back propping until the sill is in.

When the length is mined down to the top sill, which must then be got in. The front or side of it facing the length must be a little more than 15 ft. from the last toothing which extends horizontally across the length, and 2 ft. into the ground on each side behind the proposed brickwork. Working this 2 ft. is called driving the sill hole. It is an expensive piece of work in hard ground, and dynamite will be found expedient in doing it. Bring the sill into the tunnel in halves with saddle and glands loose, the ground or sill bed being levelled and the sill holes driven. Place one half in its position and level it well before slipping on half of the glands, with screwed ends pointing upwards. Set up the remaining glands in about the position they should occupy on the other half sill, and drop this half into place, fixing it over the scarf with the plates. If from wear, etc., the glands do not all fit tightly, tighten them up with wedges. Prop all the bars of this sill, taking care to collar the props and drive brobs in at both top and bottom. The back props, which have up till now been supporting the bars, may be taken out.

(To be continued.)

CONTENTS OF THIS ISSUE.

SEWAGE TREATMENT IN SASKATCHEWAN.

The Bureau of Public Health of the Province of Saskatchewan will shortly issue a number of official suggestions respecting the design of sewage treatment works for municipalities of that province. In issuing the bulletin the Commissioner of Public Health places before the people of Saskatchewan an interim outline of the more important considerations in the design of plants for the treatment of sewage. It will be found of vital and immediate importance in the conservation of the purity of water, and will doubtless be followed by others, in an aim to supply the municipal engineers of the province with a knowledge of the records and data which experimental plants on this continent and in Europe are contributing.

These suggestions, appearing on another page of this issue, are being submitted without intention of limiting in any way tendencies toward originality of design or of discouraging the incorporation of new features. To avoid mis-interpretation in this respect Dr. Seymour is making it plain that, under certain conditions, sewage treatment works designed at variance with the suggestions which are being presented, may be approved of by him, and conversely, that sewage treatment works designed strictly in accordance with these suggestions may not be approved of. It may be necessary to make such modifications as the requirements of local conditions justify.

EFFECT OF TAR ON ROAD SURFACES UPON FISH AND PLANT LIFE.

From a late reference to the subject in the London Financial News one would infer that the conclusion appears to have been arrived at on the European Continent that the use of coal tar from gasworks for the treatment of road surfaces has a number of drawbacks, not the least of which is that all vegetation in the vicinity of roads which have been tar-sprayed suffers heavily. Another of almost equal importance is that it appears to be impossible for fish to live in those streams which receive, either directly or indirectly, the drainage from their surfaces.

Engineers in America and Great Britain do not agree with the contention, and a number of facts have been tabulated which appear to show that the conclusions have been altogether of too sweeping a character. The "Journal of Austrian Gas and Water Engineers" recently published some information on the subject, and it is interesting to note that M. Griffon, a Parisian engineer, has made careful investigations as to the effect of coal tar on neighboring vegetation, and finds that it has little or no effect, thus upsetting the conclusions of Herr H. F. Fischer in this regard. As an example of this it may be mentioned that in Bordeaux one of the principal streets has been tar-sprayed for a number of years without a single tree suffering. As the point might be raised that the trees in the vicinity might have been of a specially hardy species, he is careful to mention that among them were such varieties as maples, silver poplars, lindens, and walnuts, all of which are known as being of a particularly sensitive character. At Montpellier all the macadam roads have been sprayed with gasworks tar for several years, and the plane trees in the vicinity are in much better condition than was the case before the treatment was adopted, owing to the absence of dust under the improved conditions. At Alexandria, in Egypt, the engineer responsible has found that the treatment of the roads by crude tar has had no effect on the vegetation in the neighborhod, and he gives details of many informative

tests which he had carried out before finally committing himself to that opinion.

As regards the effect on fish life, however, all the evidence obtainable appears to show that there is much in the contention, and it would appear to be advisable to construct all roads of one or other of the tar-macadam systems at present available than to adopt a spraying method, which, after all, can only be considered as a palliative, and so ensure a lasting road surface which will withstand the exigencies of modern vehicular traffic.

CONSULTING ENGINEERS AND CONTRACTORS.

At the annual meeting of the American Institute of Consulting Engineers, Inc., held January 20th, 1914, the following report was made and adopted by the meeting:—

"The committees on Professional Practice and Ethics and Relations held a joint meeting at the Railroad Club on January 2nd, 1914, to discuss the resolution adopted by the executive committee of the General Contractors' Association on August 6th, 1913, which resolution was referred to our two committees at a meeting of the Institute on October 31st, 1913. Your committees have the honor to report to the Institute as follows:

First: In respect to charging a fee for the use of plans, it is our opinion that, when contractors are invited to bid upon any work, the necessary plans should be furnished to them by the engineer without charge. If, however, the work is to be publicly let, there should be some limitations made with regard to the number of plans to be furnished free by the engineer. We believe that in such case the public or advertised invitation for bids should provide that the plans be on view at one or more places where all bidders can conveniently call and examine them. If prospective bidders ask for the use of plans under this last condition, we believe that the engineer should require a deposit for them, which deposit may be in an amount sufficient to insure the return of the plans, and that when such plans are returned to the engineer, after the award is made, the engineer should return the amount of the deposit.

Second: We are of the opinion that a sufficient number of plans for the execution of a contract should be furnished the contractor without charge. As to the number of sets of such plans, we are unable to make any definite recommendation other than that we believe the engineer should furnish sufficient for all reasonable construction purposes, and for any number in excess thereof he should charge the cost of reproduction.

Third: We believe that the engineer employed by a private client should lend his influence against the requirement of a deposit of a certified check by a contractor bidding upon his work.

Fourth: We are of the further opinion that it would be advisable in the interest of all concerned that the subject matter of the General Contractors' resolution be discussed by a joint committee composed of equal representation from:

(a) American Institute of Consulting Engineers, Inc.
(b) American Institute of Architects.
(c) General Contractors' Association.

We therefore recommend that the secretary of the American Institute of Consulting Engineers, Inc., be directed to invite the other two associations in interest to join them in the appointment of a committee which may take up this subject to the mutual benefit and interest of all."

CANADIAN CEMENT PRODUCTION AND CONSUMPTION IN 1913.

The Department of Mines, Canada, has issued a preliminary report compiled by J. McLeish, B.A., chief of the Division of Mineral Resources and Statistics, in which it is officially stated that the financial stringency during 1913 had an immediate effect in the restriction of building operations of all kinds and its results are shown in the statistics of production and consumption of structural materials. In the case of cement, while a very substantial increase in production is shown, this has seemed chiefly to displace imported material, the increase in consumption being only 4 per cent. as against an increased production of 24 per cent. Canadian mills supplied over 97 per cent. of the consumption in 1913 as against 83 per cent. in 1912. The industry has been marked by the extension of old and the completion of new plants, the latter west of the great lakes. The total capacity of completed plants at the end of the year being about 50,000 barrels per day as compared with 36,500 barrels at the end of 1912. New plants were placed in operation at Winnipeg, Marlboro west of Edmonton, Princeton, B.C., and at Tod Inlet, Vancouver Island, B.C. The plants of the Imperial Portland Cement Company at Owen Sound and of the Crown Portland Cement Company were not operated during the year.

The total quantity of Portland cement, including slag cement and natural Portland made in 1913 was 8,880,983 barrels, an increase of 1,739,979 barrels or 24 per cent. over 1912. The quantity of Canadian cement sold or used was 8,658,922 barrels, valued at $11,227,284, or $1.29⅔ per barrel, an increase of 1,526,190 barrels or 22 per cent. and $2,120,728 or 23 per cent. in total value. The total imports of cement were 889,324 cwt., equivalent to 254,092 barrels of 350 pounds each and valued at $409,303, or an average of $1.61 per barrel, as compared with imports of 1,434,413 barrels valued at $1,969,529, or an average of $1.37, in 1912. The total consumption of Portland cement, therefore, neglecting a small export, was 8,913,014 barrels as compared with a consumption of 8,567,145 barrels in 1912, an increase of 345,869 barrels or only 4 per cent.

Detailed statistics of production during each of the past three years are shown in Table I.

Table I.

	Barrels. 1911.	Barrels. 1912.	Barrels. 1913.
Portland cement sold	5,692,915	7,132,732	8,658,922
Portland cement manufactured	5,677,539	7,141,004	8,880,983
Stock on hand Jan. 1	918,965	894,822	866,138
Stock on hand Dec. 31	903,589	903,094	1,088,199
Value of cement sold	$7,644,537	$9,106,556	$11,227,284
Wages paid	2,103,838	2,623,902	....
Men employed	3,010	3,461	....

The average price per barrel at the works in 1913 was $1.29⅔ as compared with $1.28 in 1912 and $1.34 in 1911 and 1910.

The imports of cement in 1913 included 77,356 barrels from Great Britain, 172,298 barrels from the United States, 3,443 barrels from Hong Kong and 995 barrels from other countries. The average price per barrel was $1.61 as against an average of $1.37 on imports in 1912.

Annual Consumption of Portland Cement.—The consumption of Portland cement during each of the past five years was as shown in Table II.

TABLE II.

	—Canadian—		—Imported—		Total.
Year.	Barrels.	%	Barrels.	%	Barrels.
1909	4,067,709	97	142,194	3	4,209,903
1910	4,753,975	93	349,310	7	5,103,285
1911	5,692,915	90	661,916	10	6,354,831
1912	7,132,732	83.3	1,434,413	16.7	8,567,145
1913	8,658,922	97.1	254,092	2.9	8,913,014

SEWAGE TREATMENT WORKS IN SASKATCHEWAN.

THE following suggestions with reference to the design of sewage treatment works are formulated upon principles of sewage treatment which are in accordance with present day practice, and are about to be issued by the Bureau of Public Health of the Province of Saskatchewan to serve as a guide to those preparing schemes for municipalities in the province.

Screening.—(*a*) That where sewage is to be pumped, provision be made for screening, cleaning the screens at regular intervals, and for removing and disposing of screenings.

(*b*) That where works are of a character producing a large quantity of screenings, mechanical means must be provided for their removal.

Grit Chambers.—(*a*) The function of grit chambers (or detritus tanks) being to arrest the heavier mineral particles carried in suspension, the construction of such tanks is, generally speaking, unnecessary in this province, where the majority of sewerage systems are designed on the "separate" principle.

(*b*) That in special cases where sand or other mineral particles cannot be kept out of the sewerage system, it is advisable to introduce grit chambers.

(*c*) That these be constructed in multiple compartments to take care of the varying volume of flow.

(*d*) That a lineal velocity of one foot per second be aimed at, calculated to retain the heavy mineral, but not the organic matters.

Pumping.—(*a*) That where it is necessary to raise the sewage at the works, it is advisable that all machinery be in duplicate with alternative forms of power in case of failure.

(*b*) That appliances for raising sewage be specified with reference to efficiency in dealing with solids.

Sedimentation.—(*a*) That there be at least two sedimentation tanks.

(*b*) That such tanks be so constructed that the precipitated solids are automatically and continuously removed from that portion of the tank in which precipitation takes place, and that a tank or chamber combined with, or separate from, the sedimentation tank, be provided, into which the precipitated solids may pass by gravitation immediately following settlement.

(*c*) That consequent upon the modern requirement of the continuous removal of sludge as above stated, all base slopes of sedimentation tanks be made as near to the perpendicular as is practicable, relative to general construction.

(*d*) That the tank capacity be equal to one-fifth of the dry weather flow in twenty-four hours, or equal to three hours' flow calculated upon the twenty-four hours' dry weather flow taking place in fifteen hours.

(*e*) That the cross sectional area of the tanks provide a velocity of flow of not more than .05 foot per second, while lower velocities are preferable. Flows may be either vertical or horizontal.

(*f*) That consideration be given to the design of the inlets and outlets with a view to ensuring uniformity of flow throughout the breadth of the tank, and the absence of stagnant sections; and that all channels and parts of the tanks apart from the sludge storage area, be so constructed that no solids are retained.

Sludge Storage.—(*a*) That the overall depth of the sludge storage chamber from the surface of sewage in sedimentation tank be generally not less than fifteen feet. Greater depths may be adopted, producing a more concentrated form of sludge.

(*b*) That in deep tanks, wherever possible, provision be made for breaking up the sludge at the inlet to the sludge removal pipe.

(*c*) That the capacity of the sludge storage chamber be equal to at least four months' precipitation of sludge, containing 85 per cent. of water. Greater storage capacity is preferable as septic action is delayed in winter months. The cubic capacity of the sludge storage chamber shall be taken as only that space which is below the level of the deepest point of the sedimentation tank. In general, the average accumulation of sludge may be taken as three and a half cubic yards per million gallons of sewage on the above basis of dilution.

(*d*) That ample provision be made for the escape of gases from the surface of the sludge storage chamber.

(*e*) That pipes for the conveyance of sludge be of an internal diameter of not less than eight inches and that the inclination of such pipes, where the sludge is discharged by gravity, be at least 3 per cent. and preferably 5 per cent.

Biological Filtration.—(*a*) Where a dosing or siphon chamber is constructed to regulate the flow of the sewage over the surface of filter beds, that the capacity of such chamber does not exceed a ratio of two gallons of sewage to each square yard of filter surface. For instance, if the area of the filtering surface be two hundred square yards, the capacity of the dosing chamber should not exceed four hundred gallons, representing a dose of one-half inch depth of sewage over the whole surface of the filter.

(*b*) That the depth of the filter media be not less than four feet and preferably seven feet.

(*c*) That the filter media for effluents from the above form of tank be composed of hard broken stone or other suitable material, broken from one-inch to two-inch cubes.

(*d*) That the surface area of filtering media for domestic sewage be in proportion to the population using the sewers, i.e., in proportion to the amount of oxidizable matter present in the sewage.

Where a high degree of oxidation is required, the ratio of population to surface area of filter media should be approximately 17,500 persons to the acre (or 275 square yards per 1,000 population).

This corresponds to a rate of filtration of 1,750,000 Imperial gallons per acre per day, or 155 Imperial gallons per cubic yard per day (assuming depth of filter media to be seven feet) at a per capita flow of 100 Imperial gallons per day.

The efficiency of filters will not be materially affected by increasing the rate of filtration during periods of storm

to, say, three times the above stated rate, provided that the increase in volume is due to clear water.

In cases where the volume of dilution at the point of final discharge exceeds twenty times the volume of the sewage effluent, higher rates of filtration may be adopted.

(*e*) That the method or apparatus adopted for the distribution of liquid over the filter bed, shall ensure a uniform distribution over the whole surface.

(*f*) That all filter beds be drained at the base by tile pipes or preferably by means of a false floor over the entire base of the filter.

(*g*) That sufficient provision be made for ventilation to allow of oxygen being present at all times and in all parts of the filter bed.

Humus Settling Tanks.—(*a*) That it is generally advisable to provide settling tanks for the removal of the humus which is unloaded by the filter beds from time to time.

(*b*) That such tanks be constructed in every case where disinfection of the final effluent is adopted.

(*c*) That humus tanks have a capacity equal to one forty-fifth of the dry weather flow in twenty-four hours, or equal to twenty minutes' flow calculated upon the twenty-four hours' dry weather flow taking place in fifteen hours.

(*d*) That it is desirable that such tanks have separate storage compartments as in the sedimentation tanks above described.

Disinfection.—(*a*) That where chloride of lime is used for the disinfection of the final effluent, provision be made for weighing, measuring and storing the disinfectant in a dry covered building.

(*b*) That the period of contact between the disinfectant and the sewage be not less than fifteen minutes. An open pond or lagoon will serve this purpose.

Effluent Pipe.—That the effluent from the works be discharged into the watercourse or lake in such a manner as will ensure a maximum amount of dispersion.

Housing of Tanks and Beds.—(*a*) That all parts of the works containing sewage under treatment be housed to conserve the latent heat of the sewage during low temperatures and to prevent fly nuisance in summer.

(*b*) That such covers be designed to enclose the minimum amount of space, at the same time giving room for accessibility and inspection.

(*c*) That with properly designed covers the introduction of artificial heat is unnecessary in sedimentation tanks, and may be obviated in filter beds.

(*d*) That provision be made in all covers for the access of light and for efficient ventilation.

Laboratory.—That wherever the size of a municipality or other circumstance warrants its construction, a small laboratory be provided and equipped in which simple tests may be made of the sewage and effluents.

Laying Out the Surrounding Grounds.—That provision be made in the specifications and estimates for laying out, grading and improving the appearance of the surrounding grounds by terracing and seeding the slopes.

The Sanitation Corporation, 50 Church Street, New York City, has been organized to take over the sewage disposal interests of the T. A. Gillespie Company, the East Jersey Pipe Company, and the D'Olier Centrifugal Pump & Machine Company. The new concern will also control for the United States and Canada certain German sewage apparatus and processes, including the Riensch-Wurl screen. They will specialize in apparatus for the clarification and purification of sewage, the reduction of water content in sewage sludge and the recovery of by-products from sewage sludge.

CONTRACTION AND EXPANSION OF CONCRETE ROADS.

On February 13th, 1914, Mr. R. G. Wig, of the United States Bureau of Standards, as chairman of the committee on the contraction and expansion of concrete roads, of the National Conference on Concrete Road-building, held in Chicago, February 12th to 14th, presented a report which, among other things, brought out clearly that water as well as heat plays a vital part in the varying length of a road. The following is an abstract of the report:—

The effect of contraction may be finally evidenced by cracking and that of expansion by crushing, spalling or buckling. The engineer is interested in this subject only so far as it affects the integrity of the road. The chief causes of expansion and contraction are: (1) Changes in the temperature of the concrete; (2) variation in the moisture content of concrete; (3) variation in the condition and character of the sub-base; (4) excess loading by traffic.

Effect of Temperature Changes in the Concrete.—It is generally considered that the variation in the temperature from season to season tending to cause a change in length, combined with unequal frictional resistance between the concrete and the sub-base, is the primary cause of cracking. The change in the length of concrete due to temperature is free to move ranges from 0.00000805 to 0.000004355 per degree F. per unit length, the accepted value being about 0.000006. Assuming a normal change of temperature of 90° F., the movement which would occur without restraint is about 0.00054 per unit of length.

In practical work, however, several elements enter tending to modify the temperature effect. A reduction in the moisture content of concrete would cause a contraction, while an increase would cause expansion, thus aiding or counteracting the effect of temperature. The friction on the sub-base in the case of a road will always reduce the movement. In some recent experiments made by Henry S. Spackman upon experimental slabs of 1:2:3 concrete 18 in. wide, 6 ft. 6 in. long and 6 in. thick, on a clay sub-soil, a total movement of 0.00017 per unit length was observed under a change in temperature of 65° F. between July and November. The theoretical temperature movement for this range would be 0.000384 per unit of length.

Measurements made on a concrete road by the Bureau of Standards, covering a period from October, 1912, to October, 1913, and others from June to October, 1913, show that the linear change in the concrete is not in accord with the temperature change. These measurements were made by stretching an invar tape, graduated to meters, along the road spanning several slabs and reading every second meter, the figures recorded as slab changes represent changes between the points nearest the ends of the slab. Readings were recorded to hundredths of a millimeter (0.00039 in.) There was an elongation from November to April, when it reached a maximum, followed by a shortening until August, and this is followed by an elongation until October. During this period there was a mean temperature range from 16° to 84° F.

Considerable rain fell during the later part of March and the early part of April. The contraction from April to August is contrary to the condition which should result from a rise in temperature, and this can only be explained by a drying out of the concrete sufficient in amount not only to overcome the expansion due to a temperature increase of 20° F., but also to show a sub-

stantial contraction. From August to October the slab shows expansion, which again can be explained by an increase in moisture content as there is no rise in temperature.

There are no data available to indicate the expansion which might be expected in green concrete due to a rise in temperature brought about by chemical action during setting. Several of the curves of results obtained would indicate that this setting heat might be effective in causing expansion. Temperature measurements have been taken in a number of cases, and the temperature increases were noted to range from 17° F. to 108° F. in less than 18 hours after mixing. Such a great increase in temperature as these, it is believed, would have some effect, but its magnitude can only be determined by further investigation.

A variation in the quality of the concrete may also cause a variation in the thermal co-efficient of expansion, and it will, of course, affect the movement which takes place, as the modulus of elasticity of the concrete does change with a change in the quality.

Effect of Variation in Moisture Content of Concrete.—It has been definitely established that with an increase in moisture content there is an expansion of the concrete and with a decrease in the moisture content a contraction. This phenomena is apparently true for all concretes at all ages. The magnitude of this change is not definitely known, but experiments show:—

(1) Neat cement hardening under water expands +0.15 per cent. by volume, and the increased volume is approximately 0.08 per cent. for a period of from 30 days to five years. The maximum expansion obtained at one year is nearly as great as at five years.

(2) Neat cement hardening in air contracts 0.25 per cent. by volume in from 16 weeks to five years.

(3) Cement-sand mortars change in like manner but to a lesser degree.

Experiments by the University of Michigan show the following results:—

(1) Neat cement hardening in air has an average unit linear contraction of —0.00109 at 7 days; —0.00190 at 28 days; —0.00236 at 6 months; —0.00270 at 1 year; —0.00289 at 2 years; —0.00322 at 4 years.

(2) That neat cement that has been hardened under water for three years will expand 0.0011 per unit of length, and if then exposed to air for 60 days will contract 0.0005 per unit of length less than the initial length, and will, therefore, show a total linear contraction of 0.0016 per unit of length.

(3) That neat cements under water show a linear expansion of from 0.0007 to 0.0015 per unit of length at the end of one year, and after that a very slight additional expansion.

(4) That neat cement alternately exposed to air and water will show results if platted that will form a regular saw-tooth curve.

(5) That 1.3 mortars show linear changes in the same direction as those of neat cement, but to a lesser degree. Submerged bars show a linear expansion in the first few weeks of as much as 0.0005 per unit of length, but decrease slightly after that, and then expand later to a length greater than the maximum expansion of 0.0005. Bars of 1.3 mortar in air shrink in length to an average of 0.0008 per unit of length within three months.

(6) Experiments with sections of a top coat of a cement walk which had been laid 20 years showed that it expanded when immersed 0.0005 per unit of length and contracted the same amount when again dried.

(7) Experiments with a section of stucco two years old, from a brick house showed a linear expansion when immersed of 0.0008 per unit of length in four days, and a return to its original volume when dried.

(8) Experiments with a section of cement walk in which a sample of both the top course and base were bound together showed that upon immersion the base reached its maximum expansion in 15 minutes, while it took the top coat three days to reach the same expansion.

This is interesting, partly because of the evidence of alternate bending stress in the concrete due to the more rapid expansion of the lower layer and partly because of the ultimate agreement in expansion of the top and bottom portion. This cement sidewalk was in good condition after 20 years' service.

The results of experiments made by the Bureau of Standards are shown in Table I.

Table I.—Linear Expansion of Neat Cement Stored in Various Manners.

Test piece (1 in. by 1 in. by 13 ins.) neat cement prisms.

No. of cements.	Manner of storing.	Age of test piece.	Change in length per unit of original length
6	In water	30 days	+0.00095
8	In water	30 to 60 days	+0.00105
4	In water	120 days	+0.00113
20	In water	6 to 9 months	+0.00152
6	In air	30 days	—0.00150
15	In air	30 to 60 days	—0.00167
4	In air	120 days	—0.00211
40	In air	6 to 9 months	—0.00285

It was noted that prisms which had been stored in air, when placed in water at practically any age, began expanding, the expansion proceeding in manner similar to prisms placed directly in water after moulding. Similarly, prisms stored in water contracted when removed and kept in air.

Note.—The original reading was taken on removal from damp closet 24 hours after moulding.

Investigations have not been extensive enough to form final conclusions on the effect of moisture on expansion and contraction, but the following statements may be made, which are in part applicable to concrete roads:—

All of the tests quoted above show expansion of neat cement and of mortar and concrete when the samples are hardened under water. The results show the extent of this expansion to be greater with neat cement and to decrease when the addition of sand or coarse aggregate is made.

These tests also show that neat cement mortar and concrete will contract when hardened in air and that the contraction of neat cement is the greater, while that of mortar or concrete varies with the amount of sand and coarse aggregate used in the mixture.

They show that to an age of 20 years, and possibly for all time, these changes may be looked for in concrete.

They show that the condition which would provide for a decrease in moisture content when the temperature increases and an increase in the moisture content when the temperature decreases would be an ideal one.

All these tests indicate that the effect of moisture content is very much greater than the effect of temperature change, and may be sufficient to cause a stress in the concrete opposite to that which would be caused by a normal temperature change.

A variation in the quality of the concrete will cause a variation in the tendency to expand and contract with change in moisture content, as dense mixtures absorb water less rapidly than porous mixtures.

If concrete of two qualities in a road were exposed to an equal amount of moisture for a short period, the more porous of the two would have a tendency to expand the most and would have the less strength to resist the stresses set up. Assuming only a slight change in temperature and that the frictional resistance on the sub-base was uniform, the more porous concrete would have to move the greater distance, higher tensile stresses would be set up upon drying out, and it would be the more liable to crack.

If 1-course work concrete of two qualities in the same slab in a road were similarly exposed, the same tendency would be exhibited, and this may, in certain cases, be sufficient to cause a separation of the two concretes or may cause a number of small cracks.

If in 2-course work the base is of a more porous concrete than the top, the tendency would be to have unequal expansion and contraction in the slab, due to different moisture content in these mixtures causing the bottom to move more than the top or vice versa. Also, if the concrete road is subject to a heavy rain for a considerable length of time the bottom will be exposed to moisture in the ground for a longer time than the surface and the surface will be more or less dried, due to exposure to the sun, and, consequently, the top would tend to contract while the bottom would still be expanding.

Effect of Variation in Condition and Character of Sub-base.—The condition and character of the sub-base would affect the support of the road; the amount of moisture transmitted to and from the concrete; the action of frost; and the friction on the bottom of the slab. All of these factors affect the expansion and contraction of the concrete.

If the slab of concrete is not uniformly supported, sections may be stressed, causing tension or compression in an amount sufficient to exceed the strength of the concrete, resulting in cracking. A condition illustrating this point may be found where a concrete road is built over an old stone road-bed of less width than that of the concrete slab. The foundation at the sides, which is not so compact as that at the centre, will settle more, causing expansion in the surface of the concrete slab possibly sufficient to cause a crack. While there is no experimental data available definitely establishing this point, it is believed the longitudinal cracks noted in one of the roads under examination may be thus accounted for.

The amount of moisture transmitted to and from the concrete through the sub-base depends upon the porosity and density of the material in the sub-base. The action of frost can only occur in a sub-base containing moisture in localities in which the temperature gets sufficiently low to freeze to a depth of the sub-base. This action is, therefore, dependent upon the porosity and capillarity of the sub-base material and the depth of the water table below the concrete. The effect of freezing and thawing is to place the slab in stress which may cause cracking.

From observations made it would appear that the cracks usually occur during a thaw rather than during a frost, and this may be explained by the fact that the heat may be transmitted more rapidly through the shoulders than through the centre of the road, causing unequal settlement. If the heaving action of frost does cause cracking it is usually due to raising the edge of the road, which will probably crack the lower side, which may not be apparent until the slab returns to its original position, when the crack will appear on the upper surface.

The friction on the bottom of the slab is dependent upon the condition of the sub-base. The effect of this friction is to restrain movement in the concrete; therefore, the tendency to volumetric change due to change in moisture content and thermal change would be restrained. This restraint would set up stresses in the concrete probably proportional to the restraint. This is shown in the experiments made by Mr. Spackman. Referring to these results and considering only the effect of temperature, there should have been a theoretical movement of 0.000384 per unit length, and yet only a movement of 0.00017 per unit length was obtained. An inspection of the movements recorded in Figs. 1 to 3 also shows that the movements were not in accordance with theoretical requirements. The change in moisture content is not known, and most probably had something to do with the discrepancies. Thus, the actual movement observed by Mr. Spackman due to temperature may have been greater or less than that indicated by the figures.

The longitudinal grade of the road would affect the friction on the bottom of the slab. On a 5.2 per cent. grade a slab 30 feet long was observed to have moved down hill, the joint at the upper end of the slab being decidedly open while the lower end of the slab slid upward on the adjoining slab. The joint in this case was not perpendicular to the slab. Measurements also substantiate the above conditions. This sliding may have been assisted by changes in the thermal and moisture content of the concrete.

Effect of Traffic.—The expansion and contraction of concrete is probably the least affected by loads brought upon the road by traffic than by any of the above mentioned causes. The effect is, however, not to be neglected, particularly when it acts in conjunction with an uneven settlement of the sub-base, similar to that heretofore mentioned of a slab being placed over an old stone road of less width than that of the concrete. The result would be cantilever or beam action and the consequent throwing into tension the top of the slab, which may cause cracking.

[Note.—The balance of the report dealing with the application of present knowledge to the prevention of cracks; the value of reinforcement; the effect of joints, and of character and condition of the sub-base on cracking, will follow in next issue.—Editor.]

BELL FILTRATION COMPANY SUES THE EX-MAYOR OF OTTAWA.

The Bell Filtration Company of Canada, Limited, have entered suit against ex-Mayor Ellis, of Ottawa, Ont., for $10,000 damages. Mr. Ellis, who is now an alderman of Ottawa, was defeated in the mayoralty contest early this year by Mayor McVeity.

Alderman Ellis is a strong advocate of the Gatineau Lake water scheme for Ottawa, while Mayor McVeity prefers filtration. Interviews and other matter published in the Ottawa papers tending to have an influence on the plebiscite which was to have been taken March 9th, are the cause of the suit.

The Bell Filtration Company contend that the cost of a filtration plant for Ottawa plus the capitalized cost of operation, is far less than the cost of the Binnie or Gatineau Lake scheme plus the cost of operation. It was in opposing these arguments and urging the people to vote for the Binnie scheme, evidently, that the former Mayor made statements which led to the institution of the suit for damages.

The Cleveland Bridge and Engineering Company has secured from the Argentine Government the contract for the erection of a great new reservoir at Caballio, in connection with the water supply of Buenos Ayres. Leading American, Belgian and German structural engineering firms submitted tenders.

THE CONTROL OF STREAM POLLUTION.*

By Paul Hansen,
Engineer, State Water Survey, Urbana, Ill.

IN uninhabited or even rural districts the evil results of stream pollution are practically negligible, but in urban districts streams are rendered exceedingly foul by the enormous quantities of sewage and industrial wastes poured into them from city sewers. These streams become totally unfit for pleasure purposes, the land along the banks is depreciated in value, and public water supplies drawn from the streams may be grossly contaminated and constitute an extreme danger to public health. An enormous toll in human lives is annually exacted as a result of polluted streams, not to mention the economic loss due to depreciation in property values.

To prevent the evils of stream pollution gaining too great headway, central governmental control backed by an intelligent public opinion is essential. The molding of an intelligent public opinion is, however, a rather difficult matter, for even among persons who have given considerable thought to sanitary subjects, there exist gross misconceptions as to the logical and practicable way to treat the problem of stream pollution. There has been a tendency to permit sentimentality to get the upper hand, and this has resulted in giving wide currency to some extravagant demands that are wholly impracticable. There is, however, a group of sanitary engineers who have come into intimate contact with actual problems relating to the prevention of stream pollution, and among these engineers there has gradually come about a unanimity of opinion regarding certain essential factors relating to the stream pollution problem. It will be the object of this paper to present these opinions, and the statements made will be largely based upon recent careful inquiries among sanitary engineers and others interested in sanitation.

The subject may best be treated by first considering in a broad way what the functions of a stream really are. Having reached a satisfactory conclusion upon this point, it will be possible to consider certain special uses of streams with respect to stream pollution.

General Functions of Streams.—The proper conception of a stream recognizes the dual function of watering and draining the country through which it passes. Some pollution of streams is inevitable; for with increased density of population, increased cultivation of the soil and increased numbers of urban communities, it is practically impossible to prevent the discharge of all deleterious matter into streams. It is only reasonable to require that the pollution of streams be maintained at less than a certain fixed maximum, and this permissible maximum pollution must vary according to the character of the stream, the population along the banks of the stream and the uses to which the waters of the stream are placed.

Streams Used as Sources of Public Water Supplies.—Since streams in the ordinary course of events must receive more or less contamination, it follows that public water supplies drawn from surface streams must of necessity be polluted, and should not be delivered to the consumers unless the water is first adequately purified. One exception may be made to this general rule, namely, in the case of water supplies derived from streams draining comparatively small watersheds. In such cases it is sometimes feasible for the water supply authorities to own the entire watershed and control it in such manner as to make contamination of the water courses impossible. But in general we have this question to contend with: How much pollution may be permitted to enter a stream before the water thereof is polluted to a point beyond redemption by water purification methods? This is a question that taxes the greatest ingenuity of sanitary experts, and it is always necessary for any specific problem to be considered on its particular merits in order to obtain what is the best and most economical solution.

Notwithstanding the great difficulty in defining that degree of pollution which is permissible in streams which are to be used as public water supplies after purification, there would seem to be an advantage in attempting to approximate a general rule for the control of such streams. A rule has been formulated in the light of the present available evidence, but it must be admitted that this rule is not based upon any very scientific data and it can, therefore, only be put forward tentatively, with the expectation that it will be modified from time to time as more and more experience is acquired. This rule may be stated as follows:

The time in hours required for the passage of a particle of water from a sewer outlet to the point of waterworks intake during high water multiplied by the dilution available during low water in cubic feet per second per 1,000 persons tributary to the sewers should equal a constant and this constant should not equal less than 40. This may be expressed mathematically as follows:—

$$T + D = C.$$

In which T = time in hours required for the passage of a particle of water from the sewer outlet to the waterworks intake at high water;

D = dilution available during low water in cubic feet per second per 1,000 persons tributary to the sewers; and

C = constant which it is recommended be not less than 40.

The above formula applies to streams in which there is no appreciable increase in volume of flow between the sewer outlet and the point of waterworks intake. In the case of streams which receive the discharge of large tributaries between the point of sewer outlet and the point of waterworks intake, the formula must, of course, be modified. Generally it will be merely necessary to assign a value of D, which represents the mean of the quantity of water flowing past the sewer outlet and that flowing past the waterworks intake. If the factor of safety proves to be more than 40, purification of the sewage will not be necessary for the protection of the water supply. If the factor of safety is less than 40, some form of purification will be necessary, and this may vary all the way from plain sedimentation to intermittent sand filtration followed by sterilization.

The formula, of course, is intended to be used merely as a rough guide, and it is conceivable that there are instances where it will not apply. Take, for example, the case of a very large stream, where a sufficiently large factor of safety may be obtained with the sewer outlet at a very short distance above the point of waterworks intake, and on the same side of the stream; here it is manifest, due to the impracticability of securing a mixture of the sewage with the entire volume of the stream, that the sewage must receive treatment or the waterworks intake must be extended to a point above or, at

*From a paper read at the 1913 convention of the Illinois Academy of Science.

any rate, beyond the influence of the sewer outlet. As a rough guide, however, such a formula may serve a useful purpose in narrowing down the widely divergent practice of the present time.

Streams for Recreation Purposes.—Of recent years growing importance is attached to the maintenance of our streams for pleasure purposes. Every summer there may be found scattered along the streams within a radius of fifty miles or more of our large cities numerous camps. This form of summer vacation is a comparatively cheap and normally a healthful means of recreation. It ought to be regarded as one of the means of improving the health tone of our urban communities, inasmuch as it is within the means of so great a number of people.

Under this head may be asked how high a degree of purity should be demanded in a stream which is extensively used for recreation purposes, but not for public water supply? Within the last few years much emphasis has properly been placed upon the purification of sewage by dilution, which, after all, is purification by oxygenation in which a natural resource is utilized instead of an artificially constructed purification works. It has generally been held—and in most instances rightly held—that the degree of dilution necessary is merely that which will prevent a nuisance, having reference primarily to unsightly floating matter and bad odors. For most rivers and many of the smaller streams of the country, this requirement as to the cleanness of the waters is all that is necessary.

There is, however, a certain class of streams which, because of the beauty of the country through which they flow and their specially favorable location, become highly prized for camping and recreation purposes. It is a striking circumstance, in fact, that recreation seekers nearly always look for the stream valleys, which illustrates the craving of man for a combination of land and water, by means of which nature presents her most alluring and most picturesque aspects. These streams, as a rule, have no large cities upon their banks, but merely here and there a small town or village. The sewage from such small towns and villages may not be sufficient to produce a visible contamination except possibly throughout a very short distance below the sewer outfalls. Such contamination does offend the esthetic sense, however, and undoubtedly does add some danger to public health, for the reason that, when a stream is used for recreation purposes, it will be used for boating and bathing and as a domestic supply to some extent among campers, though it may not and should not be used for drinking water. It seems to the writer that such streams as these deserve greater protection against contamination than merely to prevent nuisance.

No definite rules to apply to all cases can be laid down, but as a general principle it may be said that if such a stream is not polluted to any material extent by storm water and street wash, such as would obtain in the case of a city of considerable size located upon its banks, it would seem perfectly feasible to purify the sewage to a point where it will give no evidence of its existence even in the vicinity of the outlet. Furthermore, the sewage effluent should be sterilized by the cheap and satisfactory means of using bleaching powder, so as in large measure to guard against dangers to health among vacationists which may result from boating, bathing and domestic uses of the stream other than for drinking.

Fish and Shell Fish.—Many streams are valuable to the community on account of their fish life. It may be said, in general, that there is rarely necessity for so polluting a stream as to endanger fish life, though there are some circumstances where the continuance of certain liquid-waste-producing industries injurious to fish is of so great importance to the general welfare that fish life in certain streams must be sacrificed.

The maintenance of fish life does not necessarily imply an unpolluted stream. It is merely necessary that the alkalinity of the water be maintained and that the pollution be not so great as to absorb the dissolved oxygen in the water to an extent that will suffocate the fish. The fact is that a moderate degree of pollution favors fish life, in that it favors the growth of microscopic aquatic organisms which constitute valuable fish food. Certain difficulties have been encountered in the contamination of fish by polluted water which causes the fish to decay rapidly and become unfit for human consumption. The danger of infection of human beings with specific disease through eating fish taken from polluted streams is almost negligible, for the reason that, in this part of the world, at any rate, fish are not eaten raw. With shell fish, however, the case is quite different, because they are very frequently eaten raw. It has been a common practice along the coast to float oysters in shallow polluted waters, which causes them to become bloated and appear fat. Such an oyster perhaps makes a more delectable morsel of food, but in it may be lurking the germs of typhoid fever or some other waterborne disease. The problem of protecting the shell fish industry is a very complicated one, and all its intricacies have not been worked out. Here, again, the services of experts are needed to study each zone of shell fish pollution in the light of diverse local conditions.

Discharge of Manufacturing Wastes Into Streams.—Many of our important industries, such as paper mills, woolen mills, dye works, starch factories and tanneries require large volumes of water to carry on their industrial operations, and they also produce large volumes of waste which are capable of undergoing offensive putrefaction. The discharge of these wastes into streams often causes unsightly and malodorous conditions; yet, with the exception of tanneries, these waters do not menace the public health, since they do not contain the specific infections of disease. (Tannery wastes may contain anthrax bacilli.) In fact, some of the processes are such that the wastes are quite inimical to the existence of disease germs. In some cases it is practicable to treat the wastes so that offensive conditions in a stream may be in part or wholly relieved, but for certain industries such treatment of the wastes is prohibitively expensive.

Enjoining industries against causing objectionable stream pollution may, and in some instances actually has, necessitated the shutting down of works. It is conceivable, in the case of large industries upon which are dependent a considerable population, that an order to cease stream pollution, which is virtually an order to shut down the works, might result in great hardship without adequate returns accruing from the cleaner conditions of the stream. There may be instances, therefore, where a limited few of the streams of the country may legitimately be turned over to the manufacturing interests. Now that the stream pollution problem has become more acutely an issue and the disadvantages of filthy streams are better understood, it would not seem wise to permit waste-producing industries to be located upon any but very large streams which have an ample volume to dilute the wastes to an inoffensive condition. That is to say, the streams which are now clean should be maintained clean, for the reason that we have an ample number of

large streams which can effectually take care of wastes from waste-producing industrial plants for an indefinite period in the future.

Legal Control Over Stream Pollution.—A discussion of stream pollution would not be complete without some consideration of legal control. As already indicated, the cleanness of streams cannot be conserved unless under a central governmental supervision. If left to individual communities, very little could be expected in the way of results. Communities are not likely to be altruistic enough to spend large sums of money for sewage purification works to protect neighbors on the stream below, unless such altruism is induced by damage suits which render sewage purification the cheapest way out of the difficulty. But law-suits are costly if long drawn out, and the results are often unsatisfactory.

For successful solution it is essential that specific problems relating to stream pollution be placed in the hands of experts. It is, therefore, necessary, or at least strongly advisable, that every state have an expert commission. Among many there is a strong prejudice against commissions, inasmuch as the multiplication of commissions is looked upon as a delegation of legislative and executive powers to others than direct representatives of the people. This need not necessarily be so, however, for a law may be framed requiring in general terms that streams must be maintained in an inoffensive condition and that they shall not be detrimental to health. This leaves to the commission not arbitrary powers, but the simple function of determining points of fact within limits prescribed by prior legislative enactment. That is to say, the commission will determine when a stream is in danger of being made offensive and when it is in danger of being made detrimental to health, and thereupon decide what purification of sewage and industrial wastes is necessary, whether water supplies may or may not be taken from streams and to what extent they must be purified. Such a commission should be supplied with ample appropriations to enable it to obtain all necessary information for its guidance, whether this consists in maintaining laboratories or in carrying on experimental and research work. As even the best of commissions may at times grow arbitrary or become unduly biased in its views, there should always be made provision for ready appeal from the decisions of a commission to an independent special arbitration board of experts, and, of course, there must exist the inalienable right of appeal to the courts.

The Berlin Elevated and Underground Railway, Berlin, Germany, has recently completed, at a cost of over $2,000,000 and has opened for public service, an extension from Wittenbergplatz in Berlin to the fashionable suburb of Dahlem.

One of the most wonderful structures of its kind, and one that is said to be the only large-span bridge in the world designed for four lines of railway traffic, is the Hell Gate steel arch bridge now under construction at New York. The Long Island abutment pier is well under way and the foundation for the Ward's Island pier is complete. Fabricated steel work is already being received and the erection of the arch will probably be under way before the end of the summer. The structure will be notable for the magnitude of its chord sections. Each single section will have a weight equal to twice that of the heaviest erection parts of the great bridges already existing. The weight of the structure will average about 38,000 pounds steel and 53,000 pounds total per lineal foot. The great weight is due to the large live-load capacity provided. When it is in operation there will be a constant succession of the heaviest freight trains passing back and forth over the structure.

THE MINERAL PRODUCTION OF CANADA, 1913.

The preliminary report on mineral production in Canada in 1913, prepared by John McLeish, B.A., Chief of the Division of Mineral Resources and Statistics, shows a total value of production in the year of $144,031,047. Although estimates have been made in some cases where complete returns were not available it is probable that the final record will be a revision upward. The total value of the production in 1912 was $135,048,296 compared with which the 1913 output shows an increase of $8,982,751, or 6.65 per cent. In view of the large increase over all previous years made in mineral production in 1912 and the general trade depression and industrial restriction experienced during the latter part of 1913, the industry would appear to have made in the aggregate very satisfactory progress. The average production per capita in 1913 was $18.57 as against $18.27 in 1912 and $14.93 in 1910.

The record of annual mineral production in Canada since 1886 shows the rapid growth of the industry; not only has the total output increased from a little over $10,000,000 in 1886 to its present output, but the average production per capita has increased from $2.23 per capita to $18.57, or eight times the rate shown by the first record. This is shown in Table I.

Table I.—Annual Mineral Production in Canada Since 1886.

Year.	Value of production.	Value per capita.	Year.	Value of production.	Value per capita.
1886..	$10,221,255	$2.23	1900..	$ 64,420,877	$12.04
1887..	10,321,331	2.23	1901..	65,797,911	12.16
1888..	12,518,894	2.67	1902..	63,231,836	11.36
1889..	14,013,113	2.96	1903..	61,740,513	10.83
1890..	16,763,353	3.50	1904..	60,082,771	10.27
1891..	18,976,616	3.92	1905..	69,078,999	11.49
1892..	16,623,415	3.39	1906..	79,286,697	12.81
1893..	20,035,082	4.04	1907..	86,865,202	13.75
1894..	19,931,158	3.98	1908..	85,557,101	13.16
1895..	20,505,917	4.05	1909..	91,831,441	13.70
1896..	22,474,256	4.38	1910..	106,823,623	14.93
1897..	28,485,023	5.49	1911..	103,220,994	14.42
1898..	38,412,431	7.32	1912..	135,048,296	18.27
1899..	49,234,005	9.27	1913..	144,031,047	18.57

The continuance during 1913 of the labor strike at the mines of the Canadian Collieries (Dunsmuir) Limited, and its extension to the other collieries on Vancouver Island, seriously restricted the coal output from that district. The total value of the metals was also somewhat smaller than it might otherwise have been because of the slightly lower average prices obtained for copper and silver. A restricted demand was also reported during the latter part of the year for brick and other clay products and structural materials. While these are some of the influences that have tended to curtail the mineral output during the year, there have been, on the other hand, important increases in the production of gold, nickel, lead, amongst the metals, in asbestos, natural gas and many of the other lesser valuable non-metal products and in cement, resulting in the net increases already shown.

The production of the metals and minerals of special importance to engineers, contractors and manufacturers of their supplies is shown in Table II., in which the figures are given for the two years 1912 and 1913 in comparative form, and the increase or decrease in value shown.

Of the total production in 1913 a value of $66,127,821 or 45.9 per cent. is credited to the metals and $77,903,226 or 54.1 per cent. to the non-metallic products. The increase over the value for 1912 in metallic products was $4,955,068 or 8.1 per cent. and in non-metallic products $4,027,683 or 5.45 per cent.

Mineral Production by Provinces, 1912 and 1913.—The record of production by provinces given in Table III. shows the relative importance of the several provinces in practically the same order as last year with the exception that Saskatchewan replaces New Brunswick in last position due to a falling off in the coal and structural material production in the former province and an increase in the coal, gypsum and natural gas production in the latter. Ontario has the largest output with a value of $58,697,602, or 40.75 per cent. of the total, a slightly higher proportion than in 1912. British Columbia is second with a value of $28,529,081, or 19.81 per cent. of the total, a relative falling off; Nova Scotia takes third place with a total production of $19,305,545, or 13.4 per cent.; Alberta fourth, with $13,844,622, or 9.6 per cent.; Quebec fifth, with $13,303,649, or 9.24 per cent.

Table II.

	—1912—		—1913—		Increase (+) or decrease (—) in value.
	Quantity.	Value.	Quantity.	Value.	
		$		$	$
Pig iron ....(Short) Tons.	1,014,587	14,550,999	1,128,967	16,540,012	+1,989,013

Clay products	....	10,575,869	....	9,673,067	— 902,802
Lime ....Bush.	8,475,839	1,844,849	7,671,381	1,605,812	— 239,037
Stone	....	4,726,171	....	5,199,204	+ 473,033

There was an increased production of each of the metals except copper and silver, the most important increase being in gold with 28 per cent. Pig iron increased 11.3 per cent. in tonnage, lead 5.3 per cent., and nickel 10.8 per cent. The falling off in copper was only 1.1 per cent. in quantity although 7.6 per cent. in total value, and for silver 0.6 per cent. only in number of ounces and 2.3 per cent. in value, slightly lower average prices having been obtained for these metals.

Amongst non-metallic products increases are shown in all the important products except clays and lime. The largest increase was in natural gas with 41 per cent. in value. The cement output was greater by 21 per cent. in quantity, asbestos 18 per cent., coal 4 per cent., gypsum 10.5 per cent., salt 6.04 per cent. In the case of petroleum there was a falling off of 6 per cent. in quantity but on account of higher prices an increase of nearly 18 per cent. in total value.

The decreases in clay products and lime were respectively 8.5 per cent. and 12.9 per cent.

Table III.

	—1912—		—1913—	
	Value of production.	Per cent. of total.	Value of production.	Per cent. of total.
	$	%	$	%
*Nova Scotia ..	18,922,236	14.01	19,305,545	13.40
New Brunswick.	771,004	0.57	1,049,932	0.73
Quebec	11,656,998	8.63	13,303,649	9.24
Ontario	51,985,876	38.50	58,697,602	40.75
Manitoba	2,463,074	1.83	2,211,159	1.54

Dominion ..	135,048,296	100.00	144,031,047	100.00

*Includes a small production of lime from Prince Edward Island.

Increases are shown in each of the provinces with the exception of Manitoba, Saskatchewan and British Columbia. The largest increase—36 per cent.—is exhibited by New Brunswick. The increases in the other provinces were respectively: Alberta, 14.7 per cent.; Quebec, 14.1 per cent.; Ontario, 12.9 per cent.; Yukon, 4.3 per cent.; Nova Scotia, 2.0 per cent. The decreases were Saskatchewan nearly 23 per cent.; Manitoba 10 per cent., and British Columbia 5 per cent.

It should be remembered in dealing with these comparisons that Nova Scotia in the above record is given no credit on account of the large iron smelting and steel making industries at Sydney, New Glasgow, etc. The pig iron made here is entirely from imported ore and naturally is not credited as a Canadian mine output. The same remark applies to a large percentage of the pig iron production in Ontario as well as to the production of aluminium in Quebec.

A resolution was passed by the Canadian Mining Institute at Montreal on March 6, directing the attention of the Dominion Government to the fact that the iron industry was greatly handicapped because extensive deposits of the same high grade as were found in the United States, Newfoundland and Cuba had not yet been located in Canada, although it was believed that they existed, and that they could be found should endeavours be made. The Institute, therefore, urged the Government to take such means through the proper channels, either by a geological survey or by a special committee of experts, as would determine the extent and value of Canada's iron resources, a procedure which would add immensely to the economic wealth of the Dominion.

Coast to Coast

Edmonton, Alta.—It has been reported at Edmonton that the total deficit in 1913 for the street railway department amounted to $190,000.

Guelph, Ont.—The Fire and Light Committee at Guelph are asking the city council for an appropriation of $31,471, which is in excess of the largest amount ever requested previously.

Halifax, N.S.—At the session of the Nova Scotia government on March 4th, it was announced that during the last fiscal year there had been a total expenditure in the roads division of the department of public works of $408,090.37, the largest expenditure in any year since the organization of roads division.

Halifax, N.S.—The report on provincial railways recently submitted in the Nova Scotia legislature showed that the increase in total earnings of the subsidized railways in the province for the fiscal year 1913 was $126,835.71, or about 8 per cent. over the total earnings of 1912. Except for 2 miles of new railway built by the Dominion Coal Co., Limited, there has been no railway construction during the past year over which the province had jurisdiction.

Winnipeg, Man.—It is estimated, according to a statement presented at a recent meeting of the administration board of the Greater Winnipeg water district, that the sum of $1,332,906.29 will be spent by the end of the year on the scheme to bring Shoal Lake water into the city. The estimated expenditure by months is as follows: To March 1, 1914, $108,799.34; to April 1, $138,046.04; to May 1, $168,816.04; to June 1, $221,026.04; to July 1, $334,110.29; to August 1, $501,580.29; to September 1, $690,395.29; to October 1, $814,815.29; to November 1, $1,057,466.29; to December 1, $1,293,606.29; to January 1, 1915, $1,332,906.29.

Vancouver, B.C.—It is stated that more than 1,000 feet of the "pioneer" bore, being driven by the C.P.R. in connection with the excavation of a 5-mile, double-track tunnel through the heart of the Selkirk range, have been completed. Good progress is also being made with the cross cuts and side drifts leading into the main shaft which has already been started from the east end. Work on the "pioneer" shaft from the west side of Mount Macdonald, will most likely be started at an early date. The right-of-way at the west portal has been completed and 47 per cent. of the excavation has been done from the east side. Work on the trestles and the grading for the lines on each side of the mountain is well advanced.

Edmonton, Alta.—Compilations made by the Edmonton Industrial Association show that at least 3,000 miles of railway will be built in Alberta before the close of 1915. The C.N.R. will construct 1,000 miles, most of which will be in the northern half of the province; though it will also complete its main line in western Alberta. The C.P.R. will continue the Calgary-Edmonton line northward into the Peace River country and other northern and central sections, as soon as a survey is approved. It is stated by the president of the Edmonton, Dunvegan and British Columbia Railway Company that 125 miles of the 283 miles of road from Edmonton to Fort McMurray will be ready for grading early in May. Also work is to begin this year in the three western provinces on a line from the Ness River on the Pacific Coast, to Prince Albert, Sask., by way of Northern Alberta.

Victoria, B.C.—A settlement has been reached with the Canadian Northern Pacific Railway and the Franco-Canadian syndicate for the lease of the six acres required at Cooper's Cove to the Pacific Lock Joint Company for the purpose of drying out the pipe to be used on the waterworks flow line. The company's agents are assembling material and supplies at the Cove and this contract, the largest and most important of those to be carried out in connection with the waterworks, will be under way in a short time. Meanwhile the city is pushing the work on the trestles, which have to be made of a permanent character before the pipe is laid upon them. At present frame structures carry the track across creeks and ravines, except Sooke River, where a steel span is necessary.

Calgary, Alta.—In addition to the plans recently submitted by the City Engineer of Calgary upon the bridge at Centre Street, plans have also been provided for bridges known as Louise Bridge and Mission Bridge. The plans for the former call for a reinforced concrete bridge to replace the present structure, 600 feet long, landing just east of the present structure so that it debouches into 9th Street, at a cost of $167,000; or for a duplicate of present steel bridge, but two feet wider, to be placed directly alongside and coupled up with the present bridge, making a double steel bridge, one for north-bound and the other for south-bound traffic. This is estimated to cost $55,000. The plans for the Mission bridge are for a reinforced concrete structure, with 46-foot roadway and two 8-foot sidewalks, estimated at $77,600; or for a steel lattice girder bridge, with ornamental railing, estimated at $67,000.

Calgary, Alta.—Three separate plans and estimates have been furnished by City Engineer Craig, of Calgary, for a bridge at Centre Street, and these are now being considered by a special committee of the city council. Mr. Craig has arranged all three plans so that the south approach can start from either Centre Street or First Street West. Alternative plans are also provided for the North Hill approach. These will be either through an open cut running back into the hill some distance and bridged over at street crossings by overhead bridges, or else the approach in the north hill can be tunnelled for a short distance through the hill. The difference in cost between the tunnel and the overhead bridges will be about $3,000 in favor of the bridges, according to the engineer's estimates. The plans for all the bridges provide for length of 900 feet. The plans also provide for 40-foot roadways with two 8-foot sidewalks.

Woodstock, N.B.—Preparations for the spring work on the St. John Valley Railway are in progress. It is announced that Messrs. Kennedy and McDonald, who have an option on the section from Centreville to Grand Falls, but which contract has not been let, will have a new 100-ton steam shovel on the work by April 1st, to supplement the smaller shovel which has been used between Woodstock and Centreville. Ballasting south of Woodstock will commence on May 1st. The Dominion Bridge Company is constructing the overhead crossing at Woodstock, which is an 80-foot span, and will soon commence work on the Meduxnakik Creek bridge, which is 380-foot span, and which will probably be finished by the middle of April. The brick station at Woodstock will have a concrete foundation, and will be 140 feet long by 40 feet deep. The tenders are now in and the contract will be given and work commenced as soon as the frost is out of the ground.

Ashcroft, B.C.—One of the most difficult bridges from a construction point of view on the Canadian Northern Pacific Railway in British Columbia is approaching completion. The viaduct spans the Black canyon, a narrow gorge on the Thompson River, a few miles below Ashcroft, and 189 miles east of Port Mann. It had to be built without the aid of false

work; and the fact that the railway entered a 1,300-foot tunnel after spanning the canyon greatly increased the engineering difficulties experienced in its erection. An abutment was built on the tunnel side and the massive steel girders were placed in position by means of a huge derrick, which swung over the gorge. The main span of the bridge is 210 feet long, the total length of the structure being 245 feet. It rests on a pier which is nearly 100 feet down to rock; and it is built of truss girders and of the most substantial type. At low water the railway will cross the canyon at a height of about 80 feet.

Vancouver, B.C.—The preliminary work in connection with the dock upon which construction has commenced for Messrs. McNeill, Welsh and Willson, of Vancouver, consists of the erection of a wharf 308 feet long by 176 feet wide, a roadway approach, and the reclamation of a tract between the proposed dock and the railway bridge. The plans which have been prepared by Messrs. J. R. Matheson and Sons for the sheds and warehouse buildings to be constructed provide for two large structures 204 feet long by 75 feet wide, which will flank a central roadway and "gridiron" landing slip for scows. Additional loading facilities for barges will be provided on the western side of the wharf, and the reclaimed area between the eastern edge of the dock and the railway bridge will be utilized for trackage purposes. A strip 50 feet wide will be filled in, to connect the dock with the bridge. The warehouses will be of substantial construction and covered with galvanized iron. The roadway and the scow landings will also be enclosed. The dock will be approached by a driveway 200 feet long. A feature of the sheds will be the absence of pillars, massive trusses being used to support the roof.

Brandon, Man.—A joint power committee was formed in Brandon on March 5th, and at its session on the following day passed three resolutions, the first proclaiming that the committee recognized the importance to Manitoba of the preservation of the water powers on the Winnipeg River, and that it be represented to the government of this province that it is necessary in the provincial interests that the province vigilantly guard the rights of the province in the matter of the water flow on the said river. The second motion proposed that it be respectfully represented to the government of the province that is is expedient in the interests of this province that the matter of the distribution of electrical energy to the towns and villages, and as far as possible to the rural municipalities of this province, be made the continuous study of those experts in hydraulic and electrical engineering, and that it be represented that the matter may be a fit one upon which to invoke the continuous thought and attention of the engineering branches of the Manitoba university. The third resolution provided for securing an itemized statement of the power used between Portage and Carberry, and the same information regarding Carberry.

Victoria, B.C.—The report of the first year's work of the Water Rights Branch of the Provincial Department of Lands was given recently in the British Columbia Legislature by the Hon. W. R. Ross, Minister of Lands. He stated that a definite order of work was adopted and followed throughout the season in all the water districts into which the Province has been divided on the following basis:—Engineering investigation of old records; systematic and continuous work in stream measurement; a study of the proper duty of water; the prevention of wasteful use of water; the policing of streams; the economic distribution and delivery of water; the inspection of cisterns to determine their efficiency and safety; the determination of storage possibilities; and the investigation of water powers; also the chief draughtsman of the Water Rights Branch reports that a series of standard water rights maps, on a scale of 20 chains to the inch, has been inaugurated, and 228 of these have been drawn in 15 of the new water districts, each showing about 35 square miles, making a total of 8,000 square miles covered. Reports of engineers of the several districts are also submitted together with a series of valuable tables dealing with hydrographic stream measurements and a number of maps and diagrams showing the work of the department.

Montreal, Que.—During last summer about 60 miles of the 132 miles of macadamized road which the Quebec Government is building between Charlemagne and St. Augustin on the north side of the St. Lawrence River was levelled, and this year Mr. H. Beauregard, general contractor for the work, expects to have that district entirely completed. By next fall, it is expected that the completed road will extend as far as Berthier, which will exceed the 30 miles stipulated in the contract by 3½ miles. Mr. Beauregard has sub-let the eastern portion of his contract to Messrs. Massicotte and Gagnon, and is supervising personally the western section, or that which extends from Charlemagne to within 3½ miles of Berthier. The line for the greater part of the distance will be in full view of the St. Lawrence. Generally speaking, the old high roads are utilized, but where the grade is somewhat heavy the line deviates, the land being expropriated by the department having charge of the important work. Hundreds of gullies and ravines have to be crossed, but the statement was made yesterday by Mr. Beauregard himself that the remarkably favorable grade of 2 per cent. would be maintained throughout the entire road except a short distance near the Jacques Cartier River on the lower end of the contract. Besides the 30 miles from Charlemagne or more which the contractor expects to hand over this fall he will also level and additional stretch and everything will be done so as to secure the certainty of a completed road by the fall of 1915, the time specified in the contract.

Victoria, B.C.—The bill giving further aid to the Pacific Great Eastern Railway Company has passed its second reading in the Provincial Legislature. It provides for 30 miles of railway at $35,000 a mile, constituting an additional mileage over the 450 miles named in the original agreement between the Government and the company. This extra mileage is due to the fact that a deviation in the route was made by the engineers in the neighborhood of Clinton, as the route along the Fraser River was found not to be a feasible one, and the new alignment opened up a new section for settlement. It also provides for an increase of $7,000 per mile over the entire mileage of 480 miles, thus raising the guarantee to $42,000 a mile over the entire distance; and for 330 miles at $35,000 a mile into the Peace River country. The average cost of the Pacific Great Eastern is over $58,000 per mile, according to the estimates recently prepared by the engineers. This brings the total cost to about $27,840,000. If the guarantee is raised to $42,000 per mile, it will leave $16,000 a mile to be found by the Pacific Great Eastern, or an aggregate of $7,680,000. The whole length of the line between Vancouver and Clinton is of very heavy construction. The cost from the head of the sound to Clinton, a distance of 164 miles, has been over $61,000 per mile, or a total of something more than $10,000,000. The 44½ miles from Vancouver to the head of Howe Sound has been at the rate of $103,500 per mile, owing to expensive right of way in North Vancouver, and heavy rock excavation along the shores of English Bay and Howe Sound. The balance of the line, from Clinton to Fort George, has been of lighter construction, thereby reducing the average cost to $58,000 per mile.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page 90, a directory of such societies and their chief officials.

DOMINION LAND SURVEYORS.

The eighth annual meeting of the Dominion Land Surveyors was held in the Carnegie Library, Ottawa, March 3rd and 4th. Lectures of a scientific and practical nature were delivered by eminent members of the profession.

First Day.—Morning Session.—The President of the Association, Mr. C. F. Miles, D.L.S., was not present, as he is at present inspecting surveys in Northern Alberta. In his absence, Mr. J. J. McArthur, Assistant Commissioner of Boundary Surveys, acted as chairman.

A paper by H. G. Dixon, D.L.S., on the proposed transfer of natural resources to the western provinces provoked considerable discussion at the morning session. The western provinces having made a move to take over the management of their own natural resources, the Dominion Land Surveyors, in whose hands the work has always been, are afraid that they will lose some of their status—and, in fact, their jobs—if the provincial authorities achieve their desire. A committee was appointed to conserve the Association's interests in this matter.

Land surveying is apparently a healthy occupation. One member is 75 years of age and is still actively engaged in the rigorous duties even during the severe winter months. J. J. McArthur referred to this and pointed out what a healthy profession land surveying proved itself to be.

A paper on Arctic and Antarctic research was read by J. N. Brownlee, D.L.S., of Vancouver.

The report of Secretary-Treasurer Hubbell showed that the Association had made good progress during the year, and has a satisfactory financial balance. There are now 233 members. Motions of condolence were passed on the deaths of two of the members, J. K. McLean, D.L.S., and C. E. Johnston, D.L.S.

Afternoon Session.—A most interesting lecture, illustrated by photos and blackboard diagrams, mathematical formula, etc., was given on Tuesday afternoon. Dr. Otto Klotz, D.L.S., Chief Astronomer of the Dominion Observatory, was the speaker. The subject of the lecture was the "Seismograph" in its relation to earthquakes. While he did not deal with the causes of earthquakes, he expanded upon the results of phenomena. He mentioned an experiment which is being instituted at the Dominion Observatory to determine the physical tides of the earth, Ottawa has been selected, with three or four other points in the world, one in Germany and one in Africa, for the conduction of this experiment. A huge pit was now being dug in which the seismograph would be placed, and the experiments of the future continued. He fully explained the intricate and physical technique of the seismograph.

A useful paper on the transportation problem for survey work in the Canadian North was given by F. C. Herriott. This subject was considered of great importance, and two other papers bearing on this same subject, were read and discussed on the following day. Mr. Herriott gave many suggestions as to the best means of transportation for survey parties operating in the northern sections of Western Canada, many miles from civilization, which makes supplying the commisariat a most difficult problem. In summer there are canoe, and man-packs, while in winter months these give place to the dog-teams, or, in sections where the snow is not too deep, the pack-horse. Mr. C. F. Aylesworth, D.L.S., vice-president, occupied the chair.

Annual Banquet.—The annual banquet of the Association was held at Chateau Laurier in the evening. There were present the Minister of the Interior, Hon. Dr. Roche, Dr. Thompson, M.P., Yukon; M. McNutt, M.P., Saltcoats; H. S. Clements, M.P., Como-Atlin, B.C.; J. D. Taylor, M.P., New Westminster; Senator Casgrain, Dr. King, Director of the Dominion Observatory, and nearly a hundred Dominion land surveyors.

Among the speakers were Hon. Dr. Roche, Dr. Deville, Surveyor-General, and Senator Casgrain. The Senator is an old surveyor, by the way, and brought greetings from the Quebec Land Surveyors' Association. He was glad, he said, to have had some of his reward for his land surveying by his elevation to a body that went on for ever, and one that nothing could alter—the Canadian Senate.

Mr. George Mountain, Chief Engineer of the Railway Commission, told of his saving the Senator's life while in the wilds of Northern Quebec in a surveying party, sharing his small residue of food, when otherwise there would be no Senator Casgrain. Other interesting speeches were given during the evening by Dr. Otto Klotz, Messrs. Taylor, McNutt and Clements.

Second Day.—The attendance on Wednesday was even better than the first, a large number of the employees of the Topographical Surveys Branch, who are nearly all surveyors or assistants, were present, and the hall was again filled to overflowing.

The first paper was, "Goedetic Results and their Practical Meaning," by Mr. William Tobey, Dominion Topographical Surveyor. Another interesting paper was, "The Survey of River Lots in Manitoba," by Mr. Wm. Pearce, D.L.S. These papers elicited a lot of discussion by Mr. Thomas Shanks, Assistant Surveyor-General, Mr. A. E. Aylesworth, Mr. E. W. Hubbell Dr. Deville and others.

Several excellent papers were delivered later in the day. A paper on "Chaining," by Mr. A. H. Hawkins elicited much interest. Mr. Hawkins preferred the four-chain tape and the lighter tapes rather than the heavier. He impressed upon the surveyors present the vital importance of good chaining, and threw out many hints and suggestions for its further improvement. Several papers on "Pack Trains" had been prepared, two of which were read, one by Mr. J. M. Aitkens, D.L.S., and another by Mr. Hawkins. Transportation is one of the most important features of the surveyor's work, as he is often forced to work as much as 200 miles from railway and steamboat terminals depending on pack ponies, dog-trains, canoes and packers for the transport of the food supplies and paraphernalia. There was a lot of discussion. Messrs. J. E. Dodge, A. Milliken, Chas. Ways, Dr. Deville, E. W. Hubbell, Thomas Shanks, A. H. Hawkins, and others, participating. The laboratory for testing of chains and other surveying instruments, at Ottawa, in charge of the Topographical Surveys Branch, was described by Mr. Ways, Mr. Milliken described how the accuracy of azimuth and precise chaining was arrived at by calculation in the Topographical Surveys office.

Mr. Speight, O.L.S., brought greetings from the Ontario Land Surveyors' Association, and also described the work of base-line surveying in Northern Ontario.

The closing session in the evening was, by the kind invitation of Dr. King, held at the Royal Astronomical Observatory, when Mr. N. J. Ogilvie, D.L.S., delivered an address on "South Eastern Alaska Boundary." The surveyors had the privilege of bringing their lady friends to this meeting which they gladly accepted. All were cordially invited to inspect the instruments in use at the observatory. This was the most pleasant session of the series. The election of officers resulted as follows:—Honorary president, Dr. King; president, Mr. C. F. Aylesworth; vice-president, A. H. Hawkins, secretary-treasurer, E. W. Hubbell, Chief Inspector of Surveys, Ottawa. Executive committee: Messrs. D. H. Robertson, E. M. Dennis, A. H. Nelles, J. H. Wallace, and D. H. Dennis.

TORONTO BRANCH, CANADIAN SOCIETY OF CIVIL ENGINEERS.

The luncheon which the Toronto Branch of the Canadian Society held on Thursday, March 12th, was attended by over 100 members and friends. The chief speaker was Mr. Geo. G. Powell, Deputy City Engineer of Toronto, who gave a short address on "The Municipal Engineer," outlining the responsibilities associated with that official's work, his relation to the municipality as compared with the relation of the consulting engineer to his client, the difficulties to be surmounted in municipal service, etc. His address concluded with an optimistic plea to the young engineer, to investigate the possibilities that lie before him in the field of municipal engineering, claiming that it gives greater opportunity owing to the diversity of work within its scope, than does any other engineering field. The growing immensity of problems connected with water supply, pavements, railways and sewerage work and sewerage disposal, etc., were of such a nature as to demand a diligent search by municipal corporations for men with an up-to-date technical knowledge and experience that would qualify him as an expert in such work.

After the address had been tendered a hearty vote of thanks, the ensuing discussion involved the status of the student member among professional men in the Society, and it was generally felt that more recognition and greater opportunity for meeting those on a higher professional plane than he should be tendered him.

Mr. Hugh Lumsden, of the Transcontinental Railway, and Mr. A. L. Hertzberg, Division Engineer of the Canadian Pacific Railway, were the guests of the Branch. Prof. P. Gillespie occupied the chair in the absence of Mr. A. F. Stewart.

UNIVERSITY OF TORONTO ENGINEERING SOCIETY.

The University of Toronto Engineering Society held its annual elections on March 13th. The officers for the ensuing year are as follows:—President, E. D. Gray; Vice-President, F. T. MacPherson; Chairman of Civil Club, C. R. McCort; Chairman of Mining Club, J. M. Muir; Chairman of Mechanical and Electrical Club, K. O. Jefferson; Chairman of Architectural Club, T. Stewart Graham; Chairman of Chemical Club, J. E. Breithaupt; Fourth Year Representative, W. R. McCaffrey; Third Year Representative, J. H. Eastwood; Second Year Representative, Mr Honeywell; Treasurer, H. A. Babcock; Corresponding Secretary, R. W. Downie; Recording Secretary, T. W. McLelland; Curator, R. S. Bothwell.

The annual event had associated with it a change in the constitution of the Society whereby, for the better representation of the various branches of engineering followed at the university, the three sections; viz., electrical and mechanical, civil and architectural; chemical and mining are superseded by five clubs. This will facilitate the problem of a more suitable classification of the student membership of the Society in the presentation of technical papers.

MINING SECTION, CANADIAN SOCIETY OF CIVIL ENGINEERING.

The mining section of the Canadian Society of Civil Engineers met in Montreal on Thursday, March 12th. A paper of unusual interested entitled, "The Electrical Driving of Winding Engines and Rolling Mills," prepared by Mr. C. A. Ablett, A.M.I.C.E., and H. M. Lyons, A.M.I.E.E., was read by Mr. Ablett. The paper was an interesting description of numerous electrical installations at various mining and milling centres in different countries. It was illustrated by numerous lantern views showing Canadian, English and South African installations.

Mr. R. A. Ross, Vice-President of the Society, presided at the meeting.

THE AMERICAN PEAT SOCIETY.

It is announced that the American Peat Society will hold its 8th annual meeting at Duluth, Minn., on August 20th, 21st and 22nd, 1914. The address of the Secretary is 17 Battery Place, New York.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Deven, 47 Slate Street, Troy, N.Y.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-Treasurer. University of Pennsylvania, Philadelphia, P.A.

AMERICAN PEAT SOCIETY.—Eights Annual Meeting will be held in Duluth, Minn., on August 20, 21 and 22, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9-13, 1914. J. E. Pennybacker, Secretary, Colorado Building, Washington, D.C.

PERSONALS.

JAMES SHEPPARD, of Queenston, was recently appointed good roads superintendent of Welland County.

WARD CURLEE has been appointed City Engineer of Swift Current, Sask., to succeed Geo. D. Mackie, now of Moose Jaw. Mr. Curlee was previously assistant engineer to Mr. Mackie.

J. L. G. STUART, B.A.Sc., of the City of Toronto Roadways Department, is contemplating an extended trip through Europe for the purpose of studying transportation facilities of

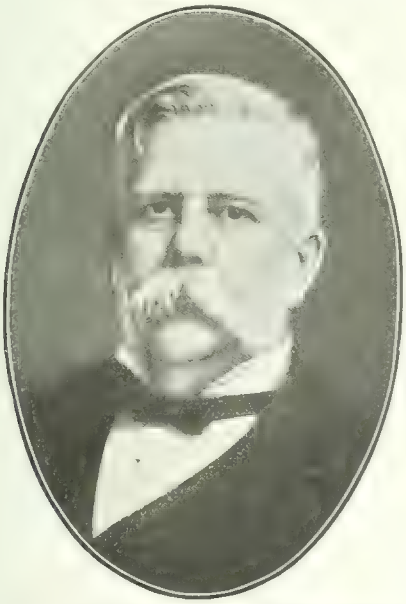
the principal cities and towns, and general municipal engineering practice. Mr. Stuart will leave about May 1st, going by way of the Mediterranean, and north through Greece and Hungary. Three months will be spent on the study of European municipal methods.

J. H. LARMONTH, who for some time has been engaged in private practice as a consulting engineer in Toronto, has been appointed superintendent of the Edmonton street railway, to succeed Mr. W. T. Woodroofe, resigned, on April 1st. Mr. Larmonth is a graduate of McGill University. He has had considerable previous experience in electric railway construction and operation, having had charge of the construction of, and later the management of, the Peterborough street railway. He was general manager of the Electric Power Company before opening an office as consulting engineer.

OBITUARY.

The death is announced of MR. GEORGE WESTINGHOUSE, engineer and inventor, who expired from heart disease at his New York residence on March 12th.

Mr. Westinghouse, whose inventions have for many years had a world-wide reputation and use, was himself the son of an inventor. He was born in 1864 in the State of New York. Before he was 15 he had invented and constructed a rotary engine, and at an early age he became an assistant engineer in the U.S.N. In 1865 he invented a device for replacing railway cars upon the track.



The Late Mr. Geo. Westinghouse.

The Westinghouse air brake, for which he is famous, is the product of a series of improvements upon what was first intended to be an automatic brake attached to the couplers. This was found unsatisfactory. The application of steam also proved unsuccessful, but was followed in 1869 by the use of compressed air and immediate success leading to manufacture. The many changes and improvements which have been made since that time have been practically all the result of Mr. Westinghouse's own investigation.

In 1880 his interest was directed toward the operation of railway signals and switches by compressed air, and the development and patenting of a system followed shortly.

In 1886 the company for the manufacture of electric lighting apparatus was organized, and in 1891 became the Westinghouse Electric and Manufacturing Company, which now employs over 22,000 people.

In connection with turbine development Mr. Westinghouse brought out the mechanical reduction gear for reducing the inherently high speed of a turbine to the slow speed of a ship propeller or d.c. generator. In other important phases of power development, such as alternating current transmission; use of natural gas; electric railway apparatus, etc., Mr. Westinghouse has played an important part. Owing to his many achievements he has been the recipient of numerous honorable distinctions, among which might be mentioned, the Scott medal of the Franklin Institute, the Edison gold medal, and the Grashof gold medal of the Society of German Engineers.

We regret to record the death of MR. ALEC. J. McMILLAN, of Victoria, B.C. Mr. McMillan, formerly a native of Pictou, N.S., has been engaged for a number of years in railway construction in Canada and the Western States. At the time of his death he was Chief Engineer of Construction for the British Columbia Mills and Timber Company, Vancouver, B.C.

The death is announced in England of MR. JOHN SCOTT, chief electrical engineer of the Commercial Cable Company, and one of the pioneer submarine telegraph engineers.

The death is announced at Boston, Mass., of MR. CHARLES MARSH CLAY, who for some time was engaged in Civil Engineering in Manitoba and the Canadian West. Mr. Clay was connected with early railroad construction in Western Canada.

PRIZES FOR HIGHWAY STUDY.

To encourage investigation of methods and materials for road and street construction and to interest engineering students in highway problems, the Barber Asphalt Paving Company has offered prizes of $100 for the best paper written by a member of the graduating classes of the leading engineering schools.

The title suggested is "Asphaltic Materials for Highway Construction." The paper and its conclusions may be based upon service tests and the lessons of experience; the physical qualities or chemistry of asphalt; or it may combine any two of these lines of investigation. The length of the paper is limited to 3,000 words and all manuscripts must be received not later than June 1, 1914.

The purpose of this prize offer is to turn the attention of engineering students to street and road construction as a field of work in which there is great need and great opportunity for trained men.

BACK COPIES WANTED.

Copies of July 21st, 1910, and November 3rd, 1910, issues of *The Canadian Engineer*, are required to complete a volume for binding. Any subscriber who has one or both of these copies for sale will please communicate with the Editor.

One of our subscribers, anxious to bind his copies of *The Canadian Engineer*, is minus the following copies: July 21st, 1910; November 17th, 1910; May 11th, 1911; May 3rd, 1912, and August 1st, 1912, and would be glad to pay 25 cents per copy for any of them. Will subscribers who happen to have these copies, and who do not care to keep them, kindly send them to this office, and we will see to it that they are put into the hands of the party interested.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21442—March 4—Relieving, for the present, G.T.R. from providing further protection at Goodwillin's crossing, 1¾ miles west of Georgetown, Ontario.

21443—March 3—Directing that Kootenay and Alberta Ry. Co., grade west approach to bridge, in Sec. 7, Tp. 6, R. 1, W. 5 M., Alta., for a distance of about 300 ft., and extend guard rail for a distance of about 150 ft.; work to be completed by June 15th, 1914.

21444—March 4—Directing that, within 60 days from date of this Order C.P.R. install improved types of automatic bells at crossing of Kyle and Queen Sts., city of Port Moody, B.C., and thereafter maintain bells at own expense. 2. 20% of cost of installing each of bells be paid out of "The Rly. Grade Crossing Fund," and remainder be borne by Railway Company.

21445—March 4—Authorizing Municipality of Tp. of Nepean, at its own expense, to construct highway crossing over C.P.R. where same intersects Second Avenue, said Twp. of Nepean, County of Carleton, Ontario.

21446—March 5—Approving and authorizing clearance, as shown on C.P.R. plan, between Co.'s standard coal sheds and rail of its side tracks.

21447—March 6—Amending Order No. 17264, dated August 21st, 1912, by striking out word "South" before word "Half" where it occurs in recital and operative parts of Order, and substituting therefor word "East."

21448—March 6—Authorizing C.P.R. to construct Swift Current Northeasterly Branch Line across highway between Secs. 5 and 6-23-27, W. 3 M., Sask., at mileage 98.47.

21449—March 5—Approving revised location of C.P.R. Bassano Easterly Branch Line, from a point of its main line in Sec. 17-21-18, W. 4 M., at mileage 0.0, thence in an easterly direction to a point in Sec. 21-22-8, W. 4 M., Alta., at mileage 72.07.

21450—March 7—Authorizing G.T.R. to reconstruct bridge No. 49, mileage 123.75 from Black Rock, 20th Dist., over public road between Lots 5 and 6, Con. 1, Tp. Fullarton, Co. Perth, Ontario.

21451—March 6—Directing that the G.T.P. Ry. forthwith appoint a regular station agent at Cudworth Station, Sask.

21452—March 9—Authorizing Rural Municipality of Usborne, No. 310, Sask., to open up crossing over C.P.R. Pheasant Hills Branch at mileage 260.8, on East Boundary, S.E. ¼ Sec. 34-33-23, W. 2 M., Sask.

21453—March 9—Declaring that the land applied for (at Tappen, B.C., in Little Shuswap Indian Reserve, No. 5), is required by C.P.R. for railway purposes, and is land which, were it the property of a private owner, could be taken without consent of owner.

21454—March 9—Authorizing C.P.R. to reconstruct bridge 37.6 over Saugeen River, on Walkerton Subdivision, Ont. Division, Ont. And rescinding Order No. 20604, dated September 25th, 1912.

21455—March 9—Approving location C.P.R. station at Cadillac, in N.W. ¼ of Sec. 8-9-13, W. 3 M., Sask., on Co.'s Weyburn-Stirling Branch.

[illegible]456—March [illegible]—Authorizing G.T.R. to use and operate two (2) bridges—namely, No. 12, mileage 48.98, 30th Dist., P.Q., and No. 13, mileage 49.20, 30th Dist., Quebec.

21457—March 9—Authorizing C.P.R. to use and operate four (4) bridges—namely, No. 24.1, Eastern Div., St. Guil[illegible] Eastern Div., Newport Subdivision, No. 32.6, Eastern Div., Ottawa Subdivision, Ont., and No. 44.7, Eastern Div., Ottawa Subdivision, Ontario.

21458—March 9—Authorizing the C.P.R. to construct spur for T. W. Murray across gravel road and part lots 1, Con. 7, West of Yonge St., Twp. Vaughan, Ont.

21459—March 10—Approving location C.P.R. station at Shaunavon, Weyburn-Sterling Branch, Sask.

21460—March 9—Approving revised location of portion of Kootenay Central Ry. from mileage 91.85 to mileage 94.81, and authorizing applicant to cross with tracks of said line of railway Laurier St. and Borden St., in town-site of Athalmer, B.C.

21461—March 9—Directing C.P.R. forthwith to re-open station at Dunkirk, Sask., and re-appoint a station agent at that point.

21462—March 9—Relieving for the present the Pere Marquette R. from providing further protection at its crossing over public road just west of Renwick Station, Ont.

21463—March 10—Authorizing the V.V. and E. and Nav. Co. to construct a spur to the premises of the British Columbia Milk Condensing Co., Limited, at Guichon, B.C.

21464—March 9—Authorizing the C.P.R. to construct its Weyburn-Sterling Branch across highways between mileage 232.523 and 253.34 (23).

21465—March 10—Approving revision of grades and alignment between certain points on the Webbwood Subdivision and Algoma Subdivision of the Lake Superior Div. of the C.P.R.

21466—March 9—Ordering the C.P.R. within ninety days from date of this Order, to install improved type of automatic bell where its railway crosses the highway known as the White Lake Road, in the Village of Pakenham, Ont., and that all switching movements on the sidings be flagged over said crossing by a member of the train crew.

21467—March 11—Authorizing the Lake Erie and Northern Ry. to operate its trains, temporarily, for a period of ninety days from date of this Order, for the purpose of construction only, across the tracks of the Grand Valley Ry. Co. at station 372.60, near Paris, Ont.

21468—March 12—Amending Order 21345 by striking out the word "reconstruct" in the recital and operative parts of the said Order, and substituting therefor the word "construct."

21469—March 12—Approving locations of C.P.R. stations Notukeu and Pontiex on its line of railway in the Province of Saskatchewan.

21470—March 10—Extending the time within which to complete siding to and into the premises of Messrs. Whiteside and Arnold, on Lots 2 and 3, south of Tiffin St., in the town of Barrie, Ont., for a period of ninety days from date of this Order.

21471—March 12—Authorizing the G.T.R. to use and operate its trains over the bridge 168 across the Thames River, immediately west of London, Ont., at mileage 121.24 on the 17th Dist. of its line of railway.

21472—March 11—Authorizing the G.T.R. to use and operate the bridge carrying its line of railway across Elgin St., in city of Brantford, at mileage [illegible] on the 20th Dist. of its line of railway.

21473—March 12—Authorizing the G.T.R. to use and operate bridge No. 30, at mileage 83.60, 20th Dist., crossing River St., Paris, Ont.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

THE FIELD WORK OF THE LETHBRIDGE VIADUCT

With some Notes on the Construction of the Substructure

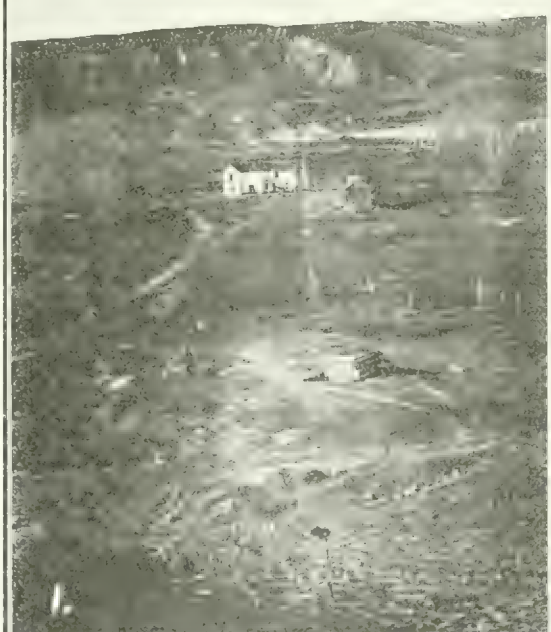
By B. RIPLEY, M. Can. Soc. C.E., M. Am. Soc. C.E.
Engineer of Grade Separation, Canadian Pacific Railway, Toronto.

IN the issue for September 17th, 1909, of *The Canadian Engineer* in an article entitled "Great Engineering Works on the Canadian Pacific Railway," the late J. E. Schwitzer, then Assistant Chief Engineer of C.P.R., western lines, dealt briefly on the construction of the Lethbridge viaduct and the spiral tunnels between Field and Hector. Subsequently, shortly after the opening of the Lethbridge viaduct for traffic, a most interesting and valuable paper was read before the Canadian Society of Civil Engineers by C. N. Monsarrat, Esq., a member of that society, now chairman of the Board of Engineers for the Quebec Bridge. This latter paper dealt chiefly with the design of the viaduct and its erection, touching briefly on the laying out of the substructure.

The author will endeavor to describe fully, the procedure adopted in connection with the laying out of the work, and the manner in which it was carried out in the field; also to describe some features of interest in connection with the construction of the foundations.

Up till 1894, the City of Lethbridge was the western terminus of a narrow gauge railway between that city and Dunmore Junction on the C.P.R. main line near Medicine Hat, then operated by the Alberta Railway and Coal Company, who, if the author remembers correctly, held the original charter for the building of the Crow's Nest Pass Railway. The Alberta Railway and Coal Company, also, before being taken over by the Canadian Pacific Railway, made extensive surveys to effect a crossing over the Belly River in the neighborhood of where the Lethbridge viaduct now stands.

The narrow gauge railway between Dunmore Jct. and Lethbridge was finally bought out by the C.P.R. and standardized, and the Crow's Nest Pass branch was built by them during 1897 and 1898, connecting Medicine Hat, on the main line, with Kootenay Landing, on the south end of Kootenay Lake. The Lethbridge-Macleod cut-off is a portion, approximately 31¾ mi. long, of the Crow's Nest Pass Branch of the Canadian Pacific Railway which was opened for traffic on November 1st, 1909.



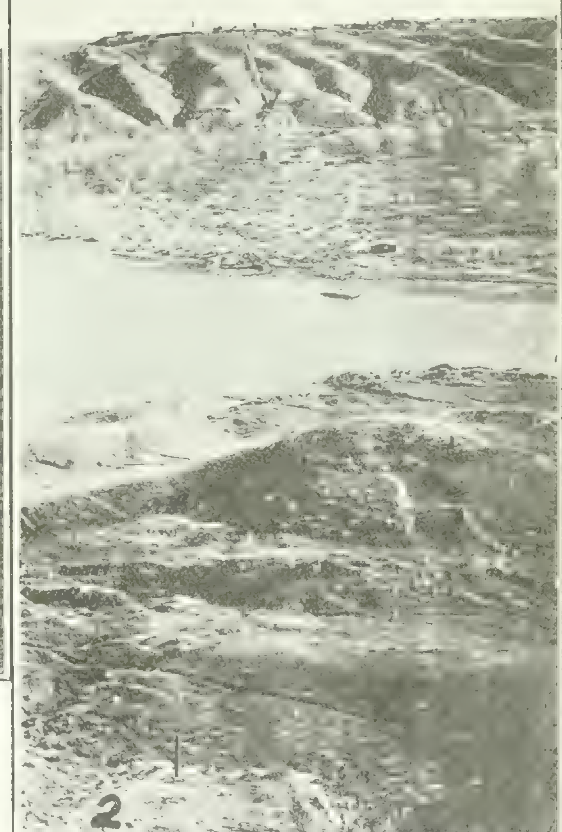


Fig. 1.—Site of the Viaduct Looking West.

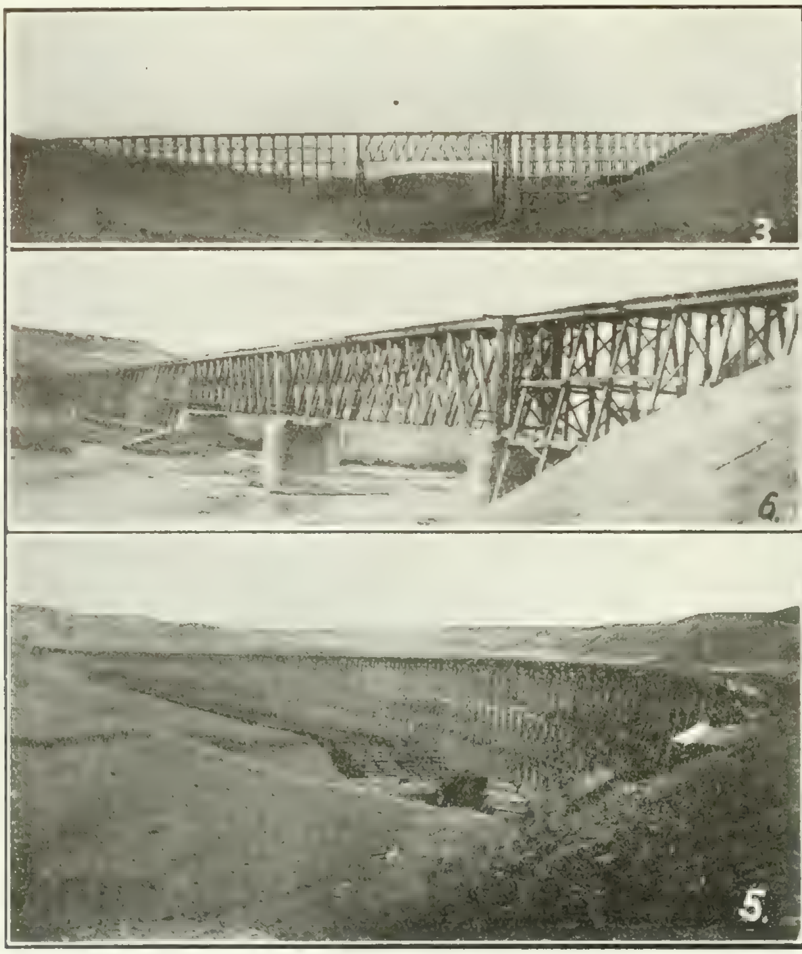
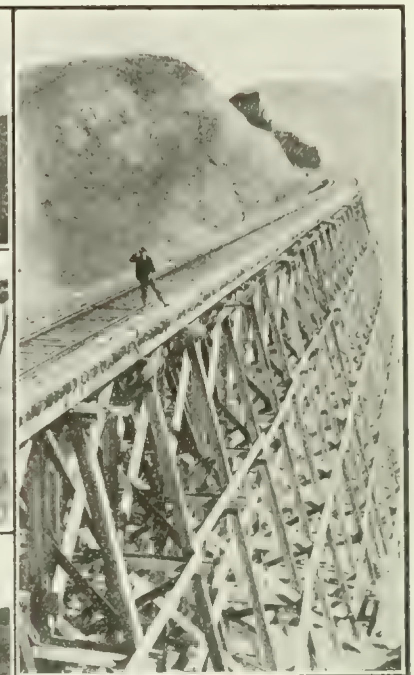
Fig. 2.—Site Looking East.

The old line between Lethbridge and Macleod, which was built during 1897 and 1898, was approximately 37 mi. long and included, besides very heavy earthwork, the construction of some 20 trestles and bridges, containing approximately 15,000,000 ft. B.M. of timber. Only two streams were crossed, and these with low-level crossings,

but in getting down to the adopted level for these, it was necessary to build other 18 trestles and trestle bridges across the mouths of deep coulees or valleys, which were tributary to the main valley or gorge. Some idea of these coulees and of the main gorge can be had from in the majority of cases the problem of complete renewal was presenting itself. Contemplating the event of such a condition, the management of the company had extensive surveys made, covering several years, to determine whether any advantage could be had by the con-

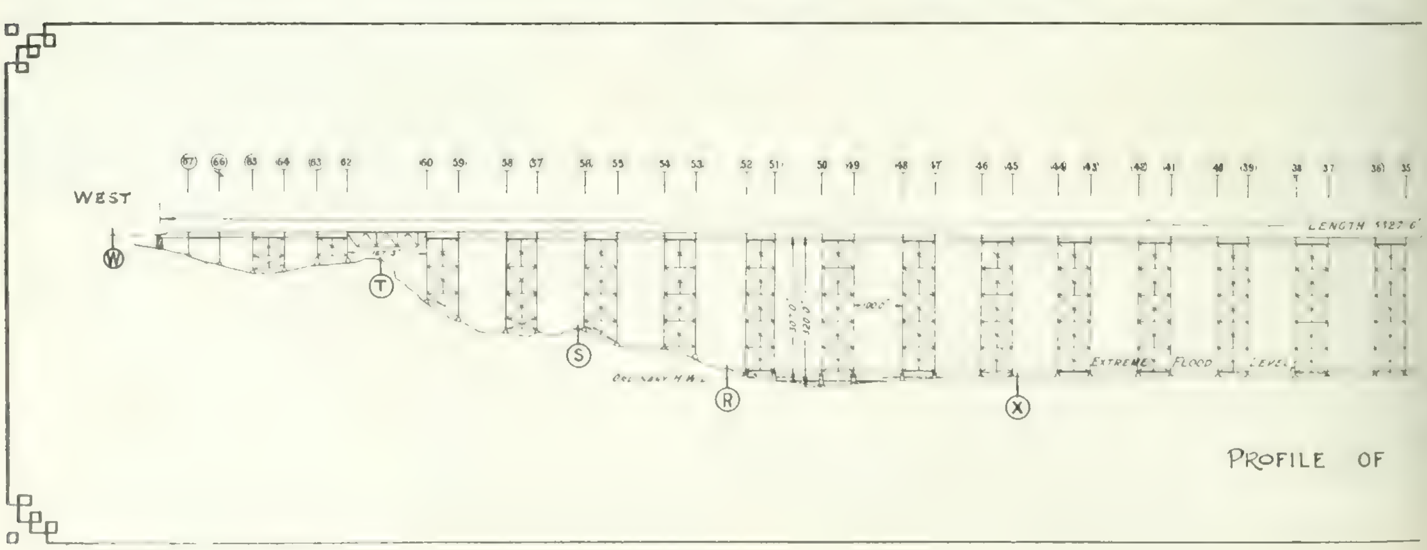




Figs. 3. and 4.—Trestles and Span Bridge over deep coulees. Figs. 5 and 6.—St. Mary's River Bridge, taken from west and east ends respectively. Piles 100 to 120 feet in length were used.

Figs. 1 and 2, and of the trestles and bridges which were built from Figs. 3, 4, 5 and 6, the two last mentioned showing the crossing of the St. Mary's River, about twelve miles above Lethbridge.

Operating expenses on the old line were very heavy. The life of a great many of the old structures had almost expired, making the maintenance of these excessive; and struction of any possible alternative line, and finally one located by F. M. Young, Esq., M.Can.Soc.C.E., now engineer in charge of construction on the Kootenay Central Railway, approximately 31¾ mi. long, with a gradient of 0.4 per cent., was chosen. On this line were two heavy high-level crossings—one over the Belly River at Lethbridge, and the other over the Old Man



River near Macleod. The first-mentioned crossing required a structure 5,327 ft. long and 300 ft. high, and it was decided to erect a steel viaduct with 67-ft. deck girder spans on towers and 100-ft. similar girders spanning the openings between the towers. The second of these two crossings was over the Old Man River near Macleod. This required a structure 1,890 ft. long and 150 ft. high, and it was decided to erect a steel viaduct with 45-ft. deck girder spans on towers and 60-ft. deck girders between the towers. Plate 7 shows a profile of the Lethbridge viaduct.

On the centre line, which was tangent throughout, permanent hubs were established at *W* and *F* (Plate 7), which were points near enough to the ends of the viaduct to be of value throughout the building of the bridge, but far enough from the structure that they would not be disturbed during construction. Holes, similar to post holes, were dug to a depth of between four and five feet,* and pieces of 8 x 8-in. timber were inserted in these, so that about two inches projected above the surface of the ground, which had been carefully levelled off. These were firmly tamped around with concrete, and after being centered, constituted the hubs from which the true centre line was established.

These were securely fenced, leaving a sufficient space within the enclosure to permit the setting up of a transit, and by a special arrangement, shown in Plate 8, a sighting rod was always left standing over the centre on these hubs, which was established on a small brass brad. These sighting arrangements saved considerable time, as otherwise it would have been necessary to have sent a picket man to the hubs every time they were used. As it was, the sighting rods were inspected from time to time to see that they were in true position, and were always carefully replaced after having been removed for a transit set-up.

After having carefully adjusted the transit, it was set up on *F*. Hubs *E*, *C* and *X* were established by using *W* as a foresight, then *T*, *S* and *R* were established from the west end of the line, using *F* as the foresight. Needless to say, all hubs were established in a manner similar to that of *W* and *F*, just described.

It will be noticed from the profile that in centering these points there would often be a great difference between elevations; and, in addition to having the lining hair of the transit truly vertical, and the standards carefully adjusted so that a vertical plane would be followed in depressing or elevating the telescope, double centering was used to further eliminate errors.

After having these main hubs or stations set up at the most commanding or useful points, Station *X* was chosen as the starting point for all measurements. There were several reasons for this. From *X* there was an excellent opportunity to get a sufficiently long base line for triangulation. More of the centre line could be seen from this than from any other point. At it, also, the triangulation base could be laid out at right angles to the centre line of the bridge, making it equally valuable for work in the direction of *W* as in the direction of *F*. The ground was fairly level, affording a good opportunity of measuring and checking the base line, and as it was of most importance to have the river work started first, Hub *X* would be close at hand and no delay would be had in laying out excavations for the river piers, the contractors for the substructure being already on the ground.

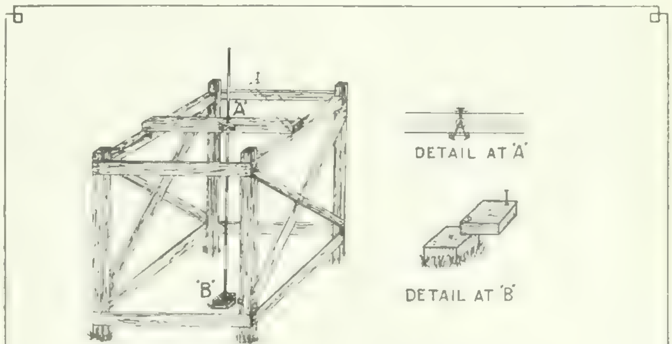


PLATE 8.

Although the centre line of the bridge had been measured both by the location engineer and the engineer making the preliminary survey from which the bridge was designed, no measurement across the gorge was made with sufficient accuracy for the construction of the foundations. It might be noted here that during the winter of 1906 and 1907, a special party was put into the field to make a preliminary survey of the site just referred to, and although extreme care was used, the final measurement, made with a steel tape, was slightly over three feet in error, as was found when the ultimate measurement was decided upon.

The banks of the gorge were very steep and irregular in places, and it was decided to start measurements in both directions from *X*, so that any error in the

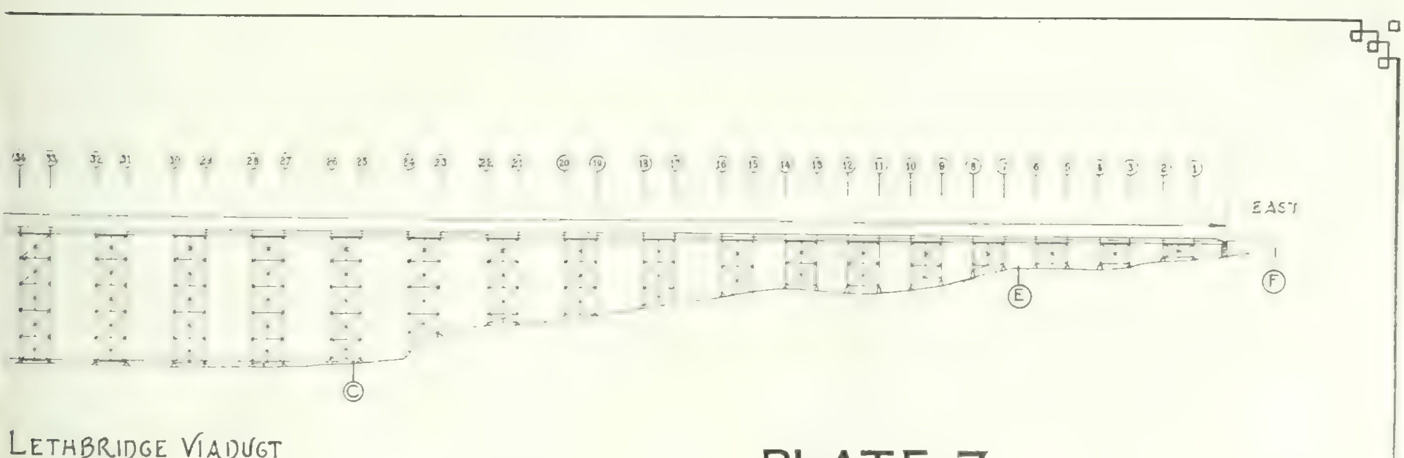

PLATE 7.

measurement of the centre line would be distributed on both banks, instead of being thrown upon one.

It might be mentioned that the actual work in connection with the laying out of the substructure was commenced during September, 1907, and at that time no detailed plans of the structure were available. Therefore, it was not safe to figure on any small errors in the total length of the viaduct being taken up by the erection of steel. It was therefore decided that nothing would be left undone in the matter of securing a correct chainage throughout the whole length of the bridge, and that nothing in the way of laying out of the different piers or bents should be done until this length was finally decided upon.

A method of measuring was then to be adopted. An unsupported steel tape was considered of little value on account of the prevalent high winds. (It should be mentioned here that the laying out of the work was commenced during a windy period which lasted till late the following April.) Neither was it considered advisable to use a supported tape for the reason that this method was not considered practicable. Therefore, on account of the wind and fluctuations in temperature, something less sensitive to both was required, and a graduated wooden rod was chosen.

A well-seasoned piece of cedar, 16 ft. long, 2 x 4-in. in section was obtained, and dressed to 1⅛ x 3 in. A supply of brass plates 2½ in. long, 1 in. wide and about 3/32 of an inch in thickness, bevelled on one long side, were made and set into the rod to receive graduations. About three inches from the end of the rod, the first one of these was placed so that the bevelled edge projected about 1/32 of an inch, and so that the surface of the plate was flush with the surface of the rod. See Plate 9 for details. This was marked with a very fine scratched line terminating at the bevelled edge, and designated zero. A plate was then put on at the 12-ft. mark, and from this point to the end of the rod, plates were put on at intervals so as to receive graduations at every tenth of a foot from the 12-ft. mark to the end of the rod.

A 100-ft. steel tape was procured, and compared with the standard of the company. Supported throughout its entire length at a temperature of 70 deg., with a 10-pd. pull, it was found to be 100.025 ft. in length. From this it was desired to establish a 90-ft. base from which to graduate the measuring rod for 15-ft. measurements. A suitable piece of ground was found, and a heavy 12 x 12-in. post about six feet long, was set into the ground about five feet, and so the top projected 12 in. above the ground, and a similar one was placed at the 90-ft. mark. Between these, other smaller stakes were firmly fixed, and on these 2 x 4-in. scantlings were nailed so that a straight line could be run on the level surface. The scantlings were left free from the 12 x 12-in. end posts so that any contraction or expansion caused by differences of humidity would not affect the main hubs on which the 90-ft. standard base was made. See Plate 10. A fine brass tack or brad, similar to those used by a shoemaker, was placed in the first post and a fine scratch made across its face. This was the zero of the standard 90-ft. base. The 90-ft. tack was set after having the tape stretched with the proper tension, calculation having been made for error in tape, also for difference of temperature, and marked as was the zero end by making a very fine scratch across the tack. Tacks were then lined in on the scantling edge that had previously been used to support the tape, and at 15-ft. intervals.

The 15-ft. mark was made very lightly on the proper plate on the measuring rod, as accurately as could be done with the steel tape. The measurement of the 90-ft. base was then attempted with the rod, and the 15-ft. graduation changed till six lengths of the rod exactly reached the 90-ft. mark on the standard base. When this was accomplished, the rod was considered correct at its 15-ft. length. The other graduations were put on by use of the common engineers' boxwood scale. The intention in measuring the length of the bridge was to place stakes at 15-ft. intervals, thereby using the 15-ft. graduation, as it was considered the more accurate of the graduations. Stakes were placed at other intervals from 12 feet to 15.5 feet only when it was impossible to place the regular 15-ft. stakes. The rod was also fitted with a reliable level bubble.

The measurement of X to C was then attempted, and the ground being fairly even and level, it was possible to measure horizontally, and without the use of a plumb-bob with one or two exceptions. Stakes were carefully lined in, stationed at 15-ft. centres, and levelled at the same time. After about five hundred feet of the

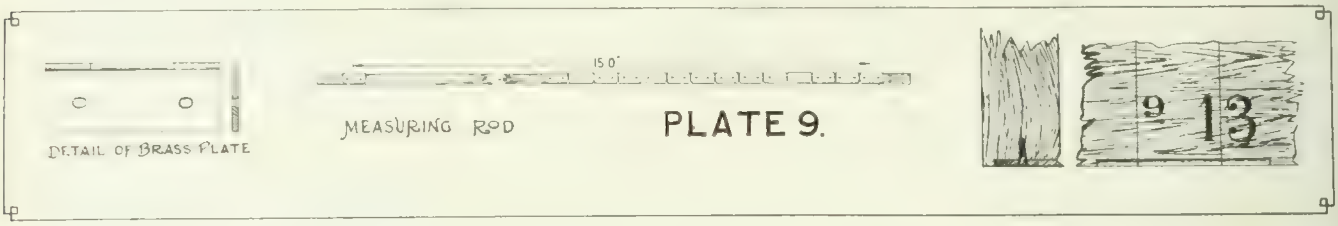

PLATE 9.

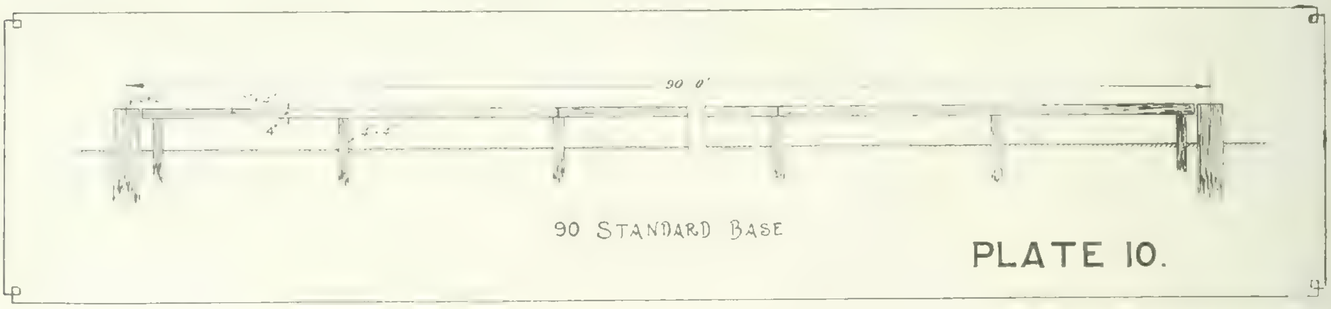

PLATE 10.

15-ft. stations were set, it was found necessary to start a new level of stakes about two feet lower than the first set, as the ground was found to be falling slightly in the direction of *C*. It was also found necessary, after this level of stations had been set for about six hundred feet, to raise the balance of the distance to a higher level. Measurement was carried from one level to another by using a fine plumb-bob protected by a canvas wind shield. See plumbing arrangement, Plate 11.

The method of measurement was as follows: Hub *X*, being the initial point, was set in concrete deeply planted in the ground as a safeguard against its being shifted, and a fine tack with a scratch across its face was made to indicate its chainage. The first set of level stations was measured after two transit points had been taken on the head of each stake, and these joined by a pencil line. This was in order that the transit need not be used while measuring was being done, so that the transitman could keep notes carefully and watch the work. With the zero end of the rod at the starting point, a tack was placed in the first station so that the 15-ft. distance would come upon its head, a fine scratch in the form of a sharp arrow was made on the tack with a small blade of a pocket knife, and this was checked to see that the 15-ft. graduation on the rod exactly coincided with the point of the arrow on the tack. To avoid confusion, no two marks were made on the same tack. The rod was then moved ahead to the second pair of stakes, and so on until a portion of the line was measured, but in no case was this distance too great to be checked three times the same day. Measurements were recorded by the transitman. The man at the zero end of the rod was then moved to the front end, the front end man being moved back to take the rear end, and the measurement checked carefully through. If any discrepancy was found, the recorder took one end of the rod and both rodmen jointly took the other end. When any differences were found, new tacks were used to receive the scratches. After a chainage was decided upon, the measuring rod was again checked into the standard 90-ft. base, and if found to be correct, the chainage previously agreed upon was allowed to stand.

After a final measurement had been agreed upon as far as hub *C*, a triangulation base was laid off south of, and at 90 degrees to the centre line from hub *X*, and this was carefully measured—759.270 feet in length, and from triangulation *X-C* was found to be 1639.115 as against 1639.110 measured with the measuring rod. See triangulation chart, Plate 12.

From *C* to *E* a great deal of steep and irregular ground was encountered, and on account of the small distance measured each time, and of the frequent uses of the plumb-bob as well as the winds, it was decided that no horizontal measurements should be taken. Some of the ground was as steep as 1 to 1½, and it would not have been practicable to have shielded the plumb line each time a measurement was taken. Slope measurements were taken in all cases, careful levels were taken over the stations and the horizontal measurements calculated. (See sample of notes, Fig. 13.) Wherever it was possible with some little grading to get two or more stations on the same slope, this was done. This simplified calculations, also reduced liability of error. On some slopes that were somewhat uniform, by a little grading it was possible to get as many as five or six stations on the same slope. The tops of these stakes were carefully lined in to the uniform slope by using a level and target rod. Wherever a change was made from one slope to another, the station where the change took place was called a "change," and this was written on the stake so that when levels were taken for the calculation of the horizontal measurements, the respective elevations of the changes only were required. The measured chainage of this portion of the bridge length was 1421.790 feet, as compared with 1421.805 feet which was computed from triangulation.

From *E* to *F*, the distance measured with the measuring rod was 547.834 feet, compared with 547.740 feet from triangulation. The west end of the work which was in the direction of *X-W*, was measured and triangulated in a similar way to the way in which the east end was done, the only difference being that point *W* was not visible from either *X* or *A*, and for this reason, a secondary base line had to be established by triangula

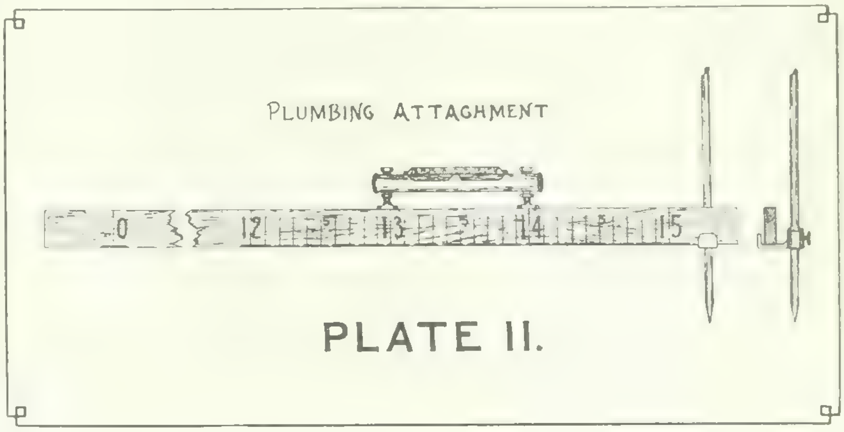

PLATE 11.

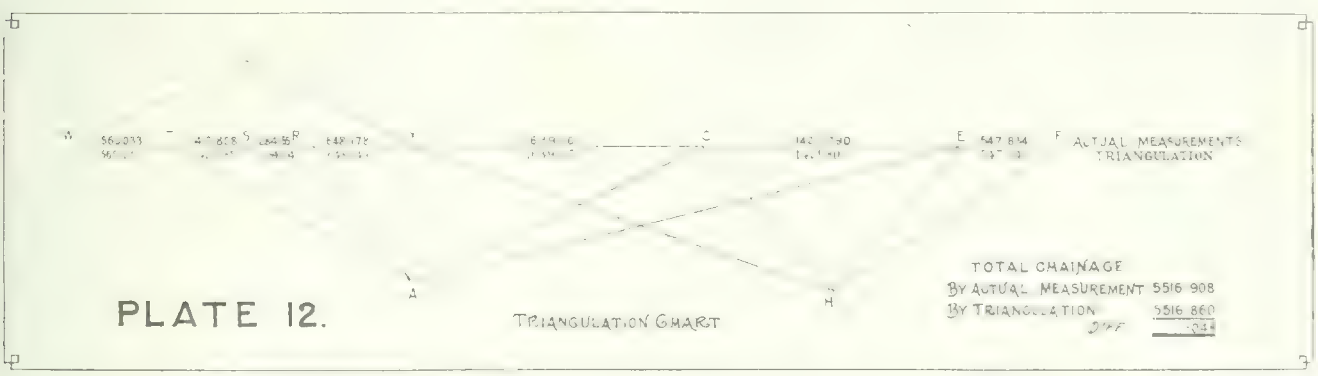

PLATE 12.

tion, and from this secondary base, the distance from T to W was had. The fact that W was not accessible from X will perhaps explain the discrepancy of .079 feet between the actual and triangulated distance between T and W, as a very slight error in the alignment of T which was accessible, would account for the difference.

Actual measurements were relied upon for the laying out of the work, and the triangulation was simply used as a means of detecting any large and appreciable errors that might possibly have come into the actual measurements, so small a measuring standard being used. Actual distance measured with the rod was 5516.908 feet, which compared favorably with the triangulated distance, which was 5516.860 feet, the difference being .048 foot, or about ½ an inch. The measuring of the centre line was considered the most difficult part of the work, and the actual measuring of the length of the bridge, slightly over a mile in length, took about six weeks of very trying time, especially on account of high winds.

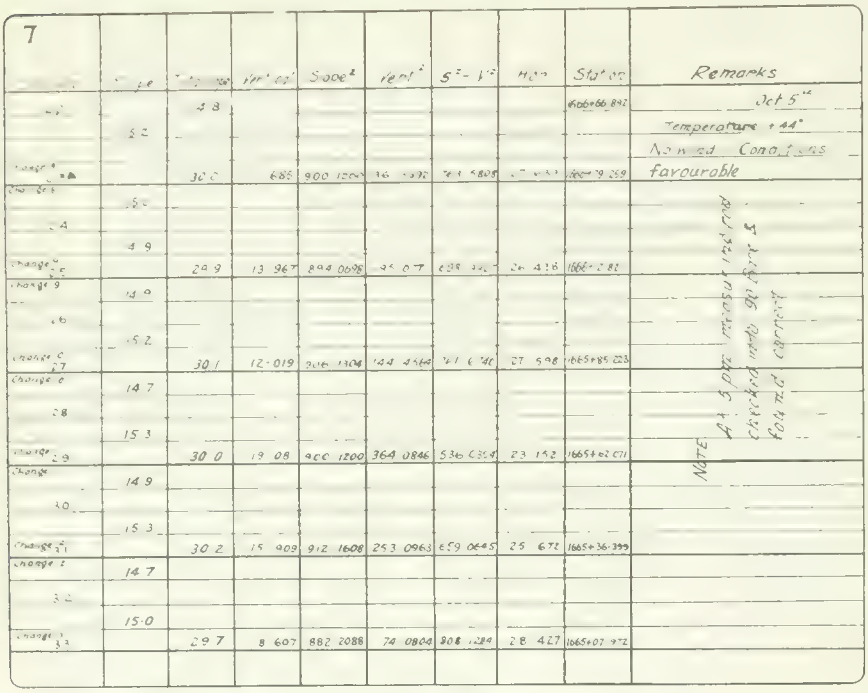

Fig. 13.—Sample Page from Field Book.

As it was necessary to proceed at once with the excavations, a great many of these were laid out immediately. The "bent" hubs were established by laying off the proper distances from the "change" stakes, the chainages of which had already been established as per notes in Fig. 13. Owing to the number of haulage roads that were to have been opened, and the number of sightseers constantly walking about, it was decided to have all bent hubs protected by a railing on four good posts set firmly into the ground, and enclosing a space sufficiently large to allow the setting up of a transit inside, and all intermediate stakes pulled out so as to avoid confusion, and to give the workmen, teams, etc., an opportunity of working without disturbing stakes. The preservation of permanent stakes and hubs was an important question on this work, and a great deal of pains was taken to protect them. The "bent" hubs were also referenced by means of other hubs set out at considerable distances, and approximately at right angles to the centre line. It will not be necessary to describe fully the actual laying out of the foundations, but it might be said that it was only necessary to turn off an angle of 90° 00″ from the centre line, and to measure out the given distance to the centre of the particular foundation. This was done by the tape on fairly level ground, but the measuring rod, and plumbing arrangement was used on irregular ground. This was generally done before the ground had been disturbed, and by setting up the transit over the centre of the foundations and turning off other angles of 90° 00″, four hubs were set that were sufficient for the contractors to carry out the work. When the ice was out of the river, the river piers were located by triangulation, which scarcely need be described. When it was possible to lay out piers from the ice, this was done in a similar way to that in which the land piers were laid out.

The initial bench mark was established from preliminary location bench marks, and inside the enclosure at hub X a hole similar to one which would have been dug for a telephone post, was made. Into this, a ⅝ inch steel rod was driven so that the top of it would be slightly below the original ground. Then concrete was dumped into the hole around the steel rod. The hole was then filled in with earth, and the bar carefully referenced, so that no unnecessary digging would have to be done in finding the rod. After the concrete had firmly set, the rod was examined to see that it had a well-defined top, on which a bench mark was established. Other bench marks were established at convenient points, from which, with one "turn," elevations could be given for the finishing of a pedestal near same. It was so arranged that it was never necessary to make more than one turn from any bench mark in setting elevations for the finishing of the tops of any of the pedestals.

In levelling to establish a system of benches, difficulty was had in the getting of fine calm days, and it was rarely possible to get two good days in succession. A Gurley level and sliding target rod were used. The levelman, after reading the rod, directed the rodman to set the target. This was then read again by the leveller, and if correct, both rodmen were instructed to read the target as a check on the leveller himself. As another precaution, after taking the final reading on the rod, the leveller was instructed to see that the bubble of the level was in the centre, and that in focusing, no jarring was done to the level. The level was always tested for adjustment every time before using, twice a day.

The levels were checked from one side of the gorge to the other several times, and although the writer is not in possession of the original notes at the present time, as far as he can remember, a check was had as close as .025 of one foot, which, considering the nature of the ground and the weather that was contended with, seems rather to have justified the care taken. The writer considers, for similar work, that a one-piece target rod is superior to the two-piece one that was used. With one of these there would be no danger of the slipping that has to be guarded against with the two-piece rod. Constant use also has a tendency to wear the mechanism of the two-piece rod, thereby making it less accurate for careful work. The sun being fairly dull at this time of the season, no sun shade was used. One precaution that was taken was that the leveling rod was, as far as possible,

kept in a place where the atmosphere was almost constant as to humidity.

Owing to the design of the steel work, it was necessary to have a precision of 1/8 inch in the finishing of the tops of the piers. Points were set for the forms, and after considerable concrete had been put in, points were set with fine nails for the finishing of the top of the pier.

The transit used was a Gurley light mountain transit that was used by the author on the harbor work of the G.T.P. at Prince Rupert, B.C., and afterwards remodelled to suit the conditions at Lethbridge. The horizontal limb and verniers were graduated to read to 20 seconds, and attached to the standards were special magnifiers for reading both limbs. These were attached to the standards by means of universal three-joint arms, allowing the lens to be placed over any point on either vernier. To further facilitate the determining of the angles required in triangulation, the process of "repetition" was used so as to distribute any inaccuracies of the graduations of the horizontal limbs, over several readings. After setting the vernier at zero, the telescope was sighted on the first point. The alidade was unclamped and swung over the necessary arc, and the telescope sighted carefully on the other point and the alidade clamped. Without reading the vernier, the limb was unclamped and the telescope carefully sighted on the first point and the limb clamped. The alidade was again unclamped and swung through the arc, and the telescope carefully sighted again on the second point and the alidade clamped. The vernier has now travelled twice over the arc, and the value of the angle is therefore one-half of the reading. This was done until the vernier indicated six times the actual value of the reading, and of course, this reading divided by six gave the value of the angles used in the computations. The angles were also read from both verniers, and in case of any difference, the mean was used. Errors due to angular distance between the verniers and to eccentricity of the graduated limb were largely eliminated by this method.

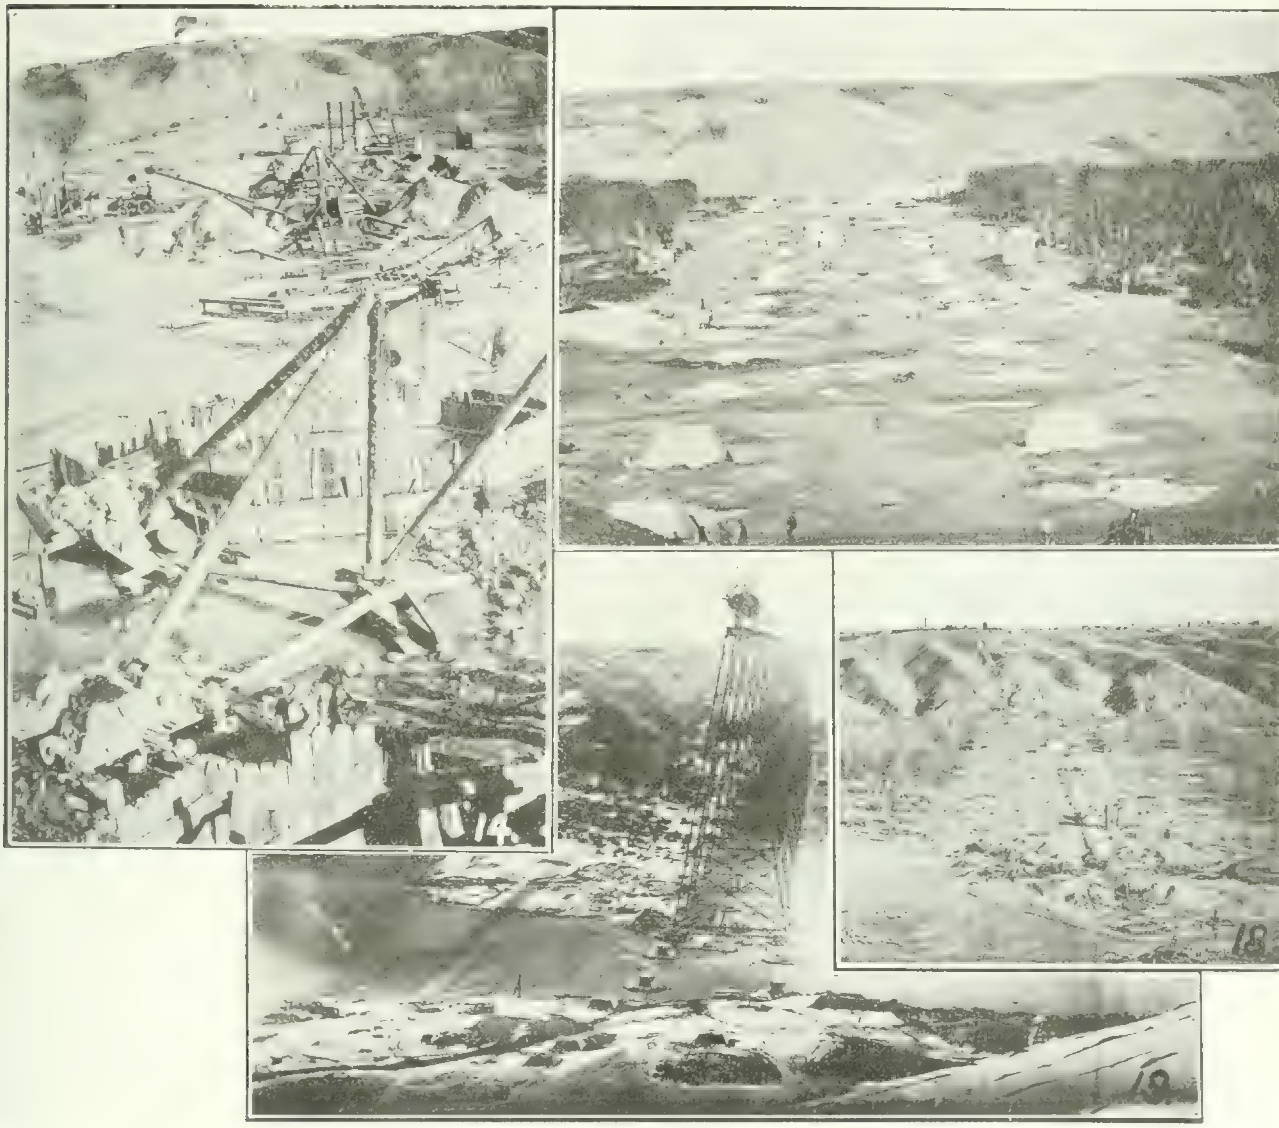

Fig. 14.—River work being carried on during winter of 1907-08. Fig. 15.—Pedestals complete on river bottom with work on west bank in progress. Fig. 18.—Looking eastward, showing sub-structure in progress. Fig. 19.—Erection of steel-work. Bent 47 just completed.

The plant used by the contractors for the substructure was as follows: 2 orange peel dredges, 1 clam shell dredge, 1 drag line dredge or excavator, 3 stiff leg

derricks, three 6-inch submerged centrifugal pumps, one 8-inch suction centrifugal pump, 3 traction engines, for steaming and driving pumps; 2 traction engines, to furnish steam for thawing out the bottoms of frozen excavations during the winter; 2 hoisting engines for handling concrete, 2 Raymond concrete pile drivers, 1 crusher with elevated bin, 2 Smith mixers, 1 Ransome mixer, and a great deal of smaller plant.

The first few feet of almost all of the land excavations were taken out by teams and scrapers, and the balance by pick and shovel. After this was done, the excavations were staked out, ready for piles, which were driven by the Raymond Concrete Pile Co. of Canada. It might be as well to describe briefly the Raymond concrete pile. A thin casing of sheet steel is made to fit a collapsible tapering core which is driven into the ground after it has received the sheet steel casing, by a heavy steam hammer. After the core with its casing has been driven to the required resistance, the core, which is made in three sections, and expanded by toggle joints before having received the casing, is collapsed and pulled out again. The casing remains in the ground, and concrete of a 1:2:4 mixture is poured into the casing, forming the concrete pile. These piles were chosen as the most suitable for the work, and gave excellent satisfaction.

bolted at the corners. The footings were filled neat to the ground wherever it was found possible to take out the excavation to the size required by the plans. On account of the formation it was rarely ever necessary to shore or timber any of the land excavations; the material invariably being stiff clay, and sometimes almost marl.

The river work, of course, was somewhat different. At the first pier, a clam shell dredge was set to work to clear off the gravel and sand from a bed of shale, which lay about 20 feet below the water, so that an open caisson when sunk would fit close to the surface of the shale. A solid 10-inch by 10-inch timber caisson was then sunk

Fig. 16.—River Piers as seen from Bent 52; cutting of west bank in progress. Height at top of the bank indicated. There is another bank not shown. Fig. 17.—Excavation for pedestals of Bent 61 in progress.

As soon as the piles were driven, any loose earth in the bottom of the excavations was taken out, and after the piles had set sufficiently, they were cut off with heavy cold chisels to allow one foot of the pile to remain in the footing of the piers. Forms were then put into place, and concrete operations commenced. The land piers being all of the same widths, and of various lengths, the forms were made so that they could be used over and over until worn out. In order that these could be readily moved about, they were made lighter than is usually the case. Good quality British Columbia flooring, ⅞ inch by 4-inch, was nailed to scantlings 2-inch by 6-inch, spaced at 18-inch centres. After the forms were placed in position, walings 6-inch by 8-inch, or 8-inch by 8-inch, were spaced around about the forms at sufficient intervals to keep the forms from bulging, and ½ inch iron tie rods were run through these and tightened up. After this, any loose scantlings or ribs were wedged so that all had a bearing on the walings. The walings were also

into place and weighted down with old rails. In making this caisson, caulking was done by tacking a strip of folded cotton to each layer of timber before putting on each successive layer of timber. Soundings with an iron rod showed up points at which the caisson was any considerable distance from the shale, and at these, light sheet piles were driven so as to scribe the shale, and in a way prevent leaks. Puddling was then done around about the bottom of the caisson, with gravel and clay. The caisson was then pumped out with two 6-inch pumps, and after making the necessary borings the footing was prepared for the placing of concrete. Before the placing of concrete was commenced, a trough was placed about one foot from the inner edge of the caisson, and caulked, and the pumping was confined to this area, so that nothing would be pumped out of the concrete.

On one or two of the other piers, another method was used. A skeleton was first made of successive rows of walings securely fastened together, conforming to the

shape of the pier to be built. These walings were placed at intervals to suit the pressure. The skeleton was then sunk into place and weighted down with steel rails. The walings referred to served a dual purpose; first as a guide to the sheet piling which was driven around them, and to receive the struts which were put in as pumping proceeded. Before any pumping was started, however, a second row of sheet piling was driven from four to five feet outside of the first row, and the intervening space was puddled.

Fig. 20.—Erection Traveller Placing the Last Girder.

From Fig. 14 a partly sunk skeleton is shown, and completed dams are shown on other parts of the work with both rows of piling driven, and one of the dams pumped out.

A third method was used where it was known to be impossible to pump out a cofferdam. Dredging was resorted to and continued until nothing further could be taken out by this method. An open caisson was then sunk into place, and as close to the shale as possible, and weighted down with old rails. Further preparation of the footing was made by divers. After a few feet of concrete had been placed in the bottom by bottom dumping buckets, the mass was allowed to set for a few days, and then pumping was resorted to. In the winter weather, steam was blown into the water near the bottom of the dam from boilers nearby, and this accelerated the setting up of the concrete. Little difficulty was found in pumping out any of the dams attempted in this manner, and after a dam was pumped out, it was a simple matter to place concrete.

The cement used was Buffalo Brand, made near Calgary, and the Exshaw Brand, made at Exshaw, Alberta. These cements were used and gave excellent satisfaction. One of the redeeming features of both brands was that they would set up fairly quickly, relieving to a great extent the pressure on the forms. When concrete was placed under water by means of bottom dumping buckets, a 1:2:4 mixture was used, and when water was not to be contended with, the concrete was of a 1:3:6 mixture.

A great deal of the gravel used came from the excavations along the river bottom proper, and was found with the proper proportion of sand, so that no screening was necessary. This proved to be very profitable for the contractors, and in one of the river piers, sufficient coal was taken from one of the excavations to feed the boilers furnishing steam for several river piers. Fig. 15 shows the pedestals at the bottom of the valley, also work proceeding on the west bank.

The large house in the centre of the picture was perhaps one of the first houses of any importance built in the North-west. It was built previous to the North-west Rebellion of 1885, and occupied by Mr. E. T. Galt, the first president of the North Western Coal and Navigation Co., which was later the Alberta Railway and Coal Co. This is the same house that is shown on Figs. 1 and 2.

Fig. 16 shows river piers for bent No. 52, with the grading of the west bank in progress.

Fig. 17 shows the excavation for foundations at piers No. 60. The necessity for the exceptional depth for these foundations was to get clear of some sliding ground indicated by cracks shown in the photograph.

Fig. 14 shows the river work in progress during the winter of 1907. A cofferdam is seen at the bottom of the picture, being pumped out. This is the excavation from which the coal was taken out. The next cofferdam above has been sheet piled, ready for pumping. Beyond this, two of the skeletons previously referred to are shown; one has been sunk into place, and the other is being sunk.

Fig. 18 shows the east bank at the Lethbridge end of the viaduct. The pedestals on the side hill are shown completed, and one row on the river bottom partly completed.

Fig. 21.—Cantilever Arm of Traveller. Note the erection cage suspended at the top of the tower.

The erection traveller has been so fully described in Mr. Monsarrat's paper, that nothing further can be said. Fig. 19, however, shows the traveller, which is also shown on Figs. 20 and 21.

This was certainly a very elaborate traveller, and so complete that the Canadian Bridge Company, who erected it, could have done nothing further to manufacture a machine for handling the steel, and provide safety for

their men. The working of the traveller need not be explained, but can be seen from Figs. 19, 20 and 21.

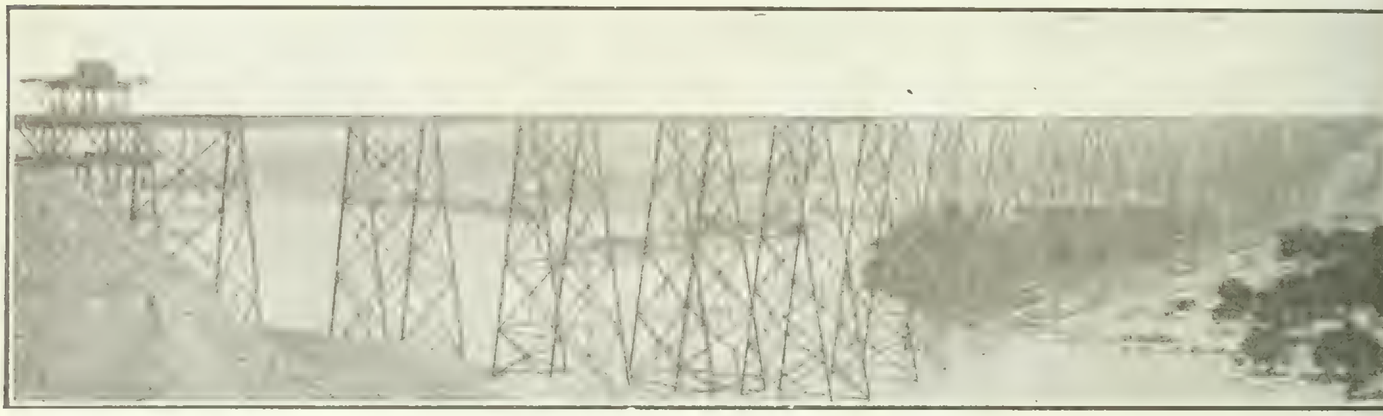
The whole work was carried out with very few accidents. One of the Canadian Bridge Company's workmen fell from the traveller, near bent No. 45 and, of course, was instantly killed, and two more men lost their lives by asphyxiation in a test hole that was sunk into the workings of an old coal mine on the east bank of the river.

The actual construction of the substructure started during September, 1907, and the bridge was opened for traffic on the 1st of November, 1909. Something like about 300 working days were required for the erection of the steel.

The bridge was designed by C. N. Monsarrat, Esq., M.Can.Soc.C.E., with Mr. C. C. Schneider, M.Can.Soc. C.E., consulting engineer. The work was handled from the office of the assistant chief engineer, Mr. J. E. Schwitzer, at Winnipeg, with Mr. F. St.C. Farran as engineer in charge of construction. The writer was assistant to Mr. Farran, and had immediate charge of the field work, in which he was ably assisted by Mr. A. F. MacDonald, now resident engineer of Bear River bridge, Dominion Atlantic Railway, and Mr. J. R. Middleton, resident engineer of Pitt River bridge, near Vancouver.

The contractors for the substructure were Messrs. John Gunn and Sons, of whom the writer cannot speak too highly in reference to the manner in which they carried out the work. This remark would apply to both the Canadian Bridge Company, who carried out the erection of the steel work, and the Raymond Concrete Pile Company, who drove the concrete piles.

Everything in connection with the work went along smoothly, and Fig. 20 shows the last girder being placed. The girder, of course, exactly reached the mark that had been set by the field party on the bridge seat of the west abutment, which was finished during the spring of 1908.



General View of Viaduct. The Riveting Traveller is seen over the Span between Bents 60 and 62.

PRODUCTION OF IRON IN CANADA IN 1913.

The iron ore shipments from Canadian mines during 1913 amounted to 307,634 short tons, valued at $629,843. These shipments included 92,386 tons of hematite and roasted siderite, 209,886 tons of magnetite and concentrates and 5,362 tons of titaniferous ore. The total ore shipments in 1912 were 215,883 short tons, valued at $523,315, and included 128,912 tons classed as magnetite and 86,971 as hematite.

Exports of iron ore from Canada during 1913 were recorded by the Customs Department as 126,124 tons, valued at $426,681. These were from Ontario, New Brunswick, Nova Scotia and Quebec. Imports, according to Customs records, in 1913 were 1,942,325 tons, valued at $3,877,824.

Shipments from the Wabana mines, Newfoundland, in 1913 by the two Canadian mines operating there were 1,605,920 short tons, of which 1,048,432 tons were shipped to Sydney and 557,488 tons to the United States and Europe.

The total production of pig iron in Canadian blast furnaces in 1913 was 1,128,967 tons of 2,000 pounds, valued at approximately $16,540,012 as compared with 1,014,587 tons, valued at $14,550,990, in 1912. Of the total production of 1913, 23,696 tons were made with charcoal as fuel and 1,105,271 tons with coke.

The classification of the production according to the purposes for which it was intended was as follows: Bessemer 265,685 tons, basic 614,845 tons, foundry and miscellaneous 248,437 tons. The amount of Canadian ore used during 1913 was 139,436 tons, imported ore 2,110,828 tons, mill cinder, etc., 33,583 tons.

The amount of coke used during the year was 1,417,148 tons, comprising 710,260 tons from Canadian coal and 706,888 tons of imported coke or coke made from imported coal. There were also used 2,206,191 bushels of charcoal. Limestone flux used amounted to 630,119 tons.

In connection with blast furnace operations there were employed 1,589 men and $1,149,345 were paid in wages.

The production of pig iron by provinces in 1912 and 1913 was as follows:—

	1912.			1913.		
	Tons.	Value. $	Value per Ton. $	Tons.	Value $	Value per Ton. $
Nova Scotia	424,994	6,374,910	15.00	480,068	7,201,020	15.00
Ontario	589,593	8,176,089	13.87	648,899	9,338,992	14.39

There was also a production in 1913 in electric furnaces of 8,075 tons of ferro alloys, valued at $493,018, compared with 7,834 tons, valued at $465,225, in 1912.

The exports of pig iron during the year are reported as 6,326 tons, valued at $351,646, an average of $55.58 per ton. Probably the greater part of this is ferro-phosphorous, produced at Buckingham, and ferro-silicon and ferro-manganese, produced at Welland.

There were imported during the year 253,843 tons of pig iron, valued at $3,234,877, charcoal pig iron 926 tons, valued at $12,528 and ferro-manganese, ferrosilicon, etc., 30,355 tons valued at $940,443.

ORGANIZATION AND METHODS OF STREET CLEANING DEPARTMENTS.*

By William H. Connell,
Chief, Bureau of Highways and Street Cleaning, Philadelphia.

(Continued from last issue.)

THE general methods of street cleaning in this country and abroad come under the following headings:—

1. Cleaning by gangs, consisting of 10 or 12 men equipped with hand brooms and the necessary appliances to clean the streets from curb to curb.

2. The blockman or patrol system in which each man is equipped with a bag or can carrier, a supply of cans or bags, broom, hand scraper or pan, sprinkler can, fire plug wrench, etc.

3. Cleaning with rotary machine brooms.

4. Flushing with squeegees which carry a tank through which water is sprinkled on the pavement and by the use of a rubber broom scraper cleanses the street.

5. Flushing with pressure flushers through which the water strikes the pavement under a pressure of 30 to 40 lbs.

6. Flushing with hose with the necessary pressure to thoroughly cleanse the pavements.

Methods of Cleaning.—In some of the larger cities in this country the method of doing this work during the past year was as follows:—

In New York the street cleaning force in the Borough of Manhattan, Bronx and Brooklyn, consisted of approximately 500 officers and 7,300 men. Each Borough was divided into districts supervised by a district superintendent and these districts sub-divided into sections supervised by section foremen. Manhattan had 13 districts and 60 sections; the Bronx 2 districts and 8 sections; Brooklyn 8 districts and 40 sections. The district superintendent covered his district in a buggy, and the section foremen used bicycles. Each district had a stable which was also the headquarters of the district superintendent, and each section had a section station, which was the office of the foreman, and where the equipment of the sweepers was stored. At 6.30 a.m. each day the sweepers, averaging about 2,875, assembled at the various section stations for roll call. They were uniformed in white suits and wore helmets in the summer time and caps in the winter. After roll call each sweeper, equipped with a can carrier and cans for the deposit of the sweepings, a scraper, broom and shovel proceeded to his designated route and covered the territory assigned to him. These routes varied in area from 5,384 square yards on the average in Manhattan, to 12,916 in Brooklyn. The sweeper first picked up the litter, then cleaned the gutters, and then swept from the centre of the street to the gutter. All the material gathered was placed in the cans, which were put on the sidewalk at the curb to await the arrival of the ash cart for their removal. In the purely business districts, as well as in the congested tenement districts, the work was done at night by cleaning gangs instead of blockmen. The method of machine broom cleaning, preceded by a sprinkling cart, was used as was also flushing by squeegees, pressure flushing machines and hose.

In New York City the ashes are collected daily except Sunday, one-horse metal carts with a capacity of 1½ cubic yards being used for the purpose.

Rubbish is called for when a sign is displayed in a window or other prominent place notifying the collector that rubbish is on the premises. The wagons used for this purpose are wooden carts with a capacity of 7½ cubic yards.

The department does not collect any trade waste or ashes from either office buildings or factories.

In the Borough of Manhattan the material is dumped on scows and transported to the low-lands where it is used for filling purposes. In the Borough of the Bronx, some of the material is dumped on scows and transported to the low-lands and in other cases it is hauled directly to meadows and vacant lots. In Brooklyn the material is transported by scows and also hauled by railroad to the low-lands and used for fill.

When the material is dumped on the scows it is heaped up and for transportation purposes it is necessary to trim the load so it will ride properly. During this trimming it is possible to reclaim a lot of saleable material such as paper, bottles, rubber, leather and miscellaneous junk. So valuable is this part of the work that the department sells the privilege and the contractor to whom the work is let furnishes all the labor free, and in addition pays an amount of money which brings the payment in labor and money up to approximately $300,000 per annum, according to E. H. Very, sanitary engineer, formerly of the New York Street Cleaning Department.

The garbage is collected daily except Sunday, one-horse metal carts of 1½ cubic yards capacity being used. It is loaded on scows and transported to a reduction plant at Barren Island, where it is put through the usual process of this method for the purpose of extracting the marketable products, such as grease, which is used for the manufacture of glycerine, cold creams, etc., and the tankage which is used for the filler in fertilizer.

Snow Removal.—In New York City snow is removed more extensively than in any other city in this country or probably in the world. The snow is hauled to the river front, vacant lots, etc., and the removal is paid for on the cubic yard basis.

All collections and street cleaning work in New York City are by municipal labor, the only contracts being those for the final disposal of rubbish, ashes and garbage.

City of Washington.—Street cleaning in the City of Washington is under the Street Department and is done by municipal labor. Only the blockmen are in uniform, wearing white suits and white canvas hats. The work is subdivided as follows:—

1. Hand patrol.
2. Machine broom cleaning.
3. Squeegeeing.
4. Flushing.
5. Alley cleaning.
6. Suburban cleaning.

The hand patrol or blockmen area covers approximately 2,750,000 square yards or 55% of the area of the city, and includes the entire business section, the downtown residential section and a great deal of the better class of residential suburbs. The entire area is cleaned daily by blockmen, and 219 men are employed for this purpose. In addition, a large portion of it is either squeegeed or flushed about twice each week. This area is divided into six sections, each section having a foreman, 2 or 3 wagons, and from 19 to 49 men, the areas ranging from 308,000 to 523,000 square yards. Each

---

*Lecture delivered by Mr. William H. Connell before the Graduate Students in Highway Engineering at Columbia University on January 15th, 1914.

foreman is given absolute control over the forces under him and is directly responsible to the superintendent for the condition of the streets in his section.

The equipment used in hand patrol work consists of hand machines, bag carriers, burlap sacks, push brooms, hand scrapers, sprinkling cans and shovels. The dirt collected is placed in sacks and left at convenient points to be collected by special wagons and taken to the dump in sacks, these being returned by the drivers. Sacks are used in preference to cans because of the weight, bulk and noisiness of the latter.

After all the hard material has been removed from the streets by the blockmen, a hand machine broom is used, which picks up all the fine dust and loose droppings. In other words, the machine broom is used to polish the street and if properly used does away with the necessity for using horse-drawn machine brooms.

Machine Broom Cleaning.—The area swept with machine brooms consists of 2,220,000 square yards, or 45% of the paved area of the city, being almost entirely residential and each street being swept every other day. The force employed consists of 4 gangs, each composed of 1 sprinkler, 3 machines, 4 carts, and from 4 to 7 broomers, depending upon the conditions in the particular sections.

Streets are always swept from the centre toward the curb, the machines following one another and overlapping slightly. If the street is too broad to be swept solid in one operation, the machines turn in rotation, each taking a block, as may be required.

Squeegee Cleaning.—The area included in squeegee cleaning comprises a large portion of the smoothly paved streets in the white wing or patrol sections, amounting to about 1,786,000 square yards or 64% of the total white wing area. At the present time the method of operation is 1 sprinkler, followed by 3 machines. The sprinkler precedes the squeegees some slight distance, which allows the baked dirt to be softened by absorption, the sprinkler throwing as much water as possible without flooding the pavement. The squeegees brush the dirt to the curb, after which it is swept into piles by the white wings and hauled away.

Street Flushing.—Flushing machines are used on poorly paved streets and block pavements in the white wing area, each street being flushed about twice weekly by a high-pressure flushing machine.

Alley Cleaning.—The majority of the alleys in Washington are wide enough to be cleaned by a one-horse street sweeping machine, cleaning a 5-foot swath. Alleys are cleaned about once each week. Alleys too narrow to permit of the use of machine brooms are cleaned by hand gangs, usually consisting of a foreman and 6 men. These alleys are cleaned once per week and at stated periods are flushed with a hose.

Suburban Cleaning.—The cleaning of the suburban streets consists in keeping the gutters clear, removing all trash, loose stones and leaves.

Collection and Disposal of Ashes, Rubbish and Garbage.—The collection and disposal of ashes, rubbish and garbage in the City of Washington is done by contract. The ashes are collected semi-weekly between November 1st and April 15th, and weekly during the rest of the year, within the thickly populated districts; the remainder of the city receives weekly collections from residences, boarding houses, apartment houses containing not more than 4 families, etc. Two-horse wooden wagons of about 4 cubic yards capacity, with canvas covers, are provided for this purpose. All ashes are hauled to the authorized dumps, mostly low-lands.

Waste is collected weekly throughout the city. Single horse wagons with latticed sides, holding about 7½ cubic yards, are used for the collections. The waste is hauled to the reclamation station maintained by the contractor, where the saleable products are sorted and the balance incinerated. The paper is sorted and baled; bottles separated and crated; the other materials reclaimed are leather, rubber, tin cans and metal scraps.

Garbage is collected daily except Sundays between May 15th and October 16th, in all sections of the city within the thickly populated districts. Between October 15th and May 15th, the garbage is collected but three times a week. Outside the thickly populated sections, collections are made three times each week, both winter and summer. Hotels, hospitals, market houses, etc., are given daily service, including Sundays, throughout the year. The wagons used are one-horse metal-bodied wagons, water-tight, and with a capacity of approximately 1½ cubic yards. Garbage is disposed of by the reduction method.

Philadelphia.—Street cleaning in the City of Philadelphia is done under annual contracts, the city being divided into 8 districts and the work in under the supervision of the district engineers of the Highway Bureau and their corps of inspectors.

The specifications provide for the removal of ashes, waste and rubbish at least once each week from all buildings, and for the cleaning of all streets 6 ft. 6 in. in width or over, either by machine brooms, squeegees or flushers, in accordance with the schedule. All equipment to be operated in accordance with a schedule which specifies the streets in the order in which they are to be cleaned with the various types of equipment. Squeegee machines, high-pressure flushing machines and sprinklers are not used when the temperature conditions are such as to make their use undesirable, due to causing slippery streets in freezing weather. During the winter when this work cannot be done, additional machine brooms and gangmen must be provided to clean the streets with the frequency called for.

The total amount of yardage cleaned every day is 1,354,364 yds.; cleaned every two days, 9,898,918 yds.; cleaned every three days, 5,380,711 yds.; and cleaned once per week, 425,552 yds.; which makes an average cleaned per day of 8,134,987 yds. The total yardage of streets to be cleaned in this manner is 17,059,545. In addition to this the specifications provide for the cleaning of all alleys from one to six times per week, depending upon the necessity. There are approximately 12,000 alleys in the city under 6 ft. 6 in. in width.

The specifications also stipulate that the contractor must furnish a certain number of blockmen for each district, fully equipped with the necessary bags and bag carriers, scrapers, brooms, sprinklers, etc. The number of blockmen ranges from 57 to 140 per district. A certain number of hand machine brooms, squeegees, and flushers are also specified for each street cleaning district.

All blockmen and gangmen wear white uniforms with white helmet in the summer months and white caps in the winter months. All drivers and helpers wear khaki uniforms with khaki canvas hats in the summer and caps in the winter. Superintendents and foremen wear dark gray uniforms and caps. Inlet gangs are uniformed in khaki with hats in the summer and caps in the winter.

The following is a description of the methods of handling this work, which is divided as follows:—

1. Hand patrol.
2. Machine broom cleaning.
3. Squeegeeing.
4. Flushing.
5. Alley cleaning.

Hand Patrol.—The blockmen are assigned to sections designated by the chief of the Bureau of Highways and Street Cleaning, the area to be covered depending upon the character and amount of traffic. The duties of the blockmen consist of patrolling these areas, gathering all paper or other refuse, and sweeping street dirt as fast as it accumulates and placing it in dust-proof bags or metal cans, after which these bags or cans are collected and loaded into special wagons and hauled to a collection station or dump.

The equipment used in the hand patrol work consists of hand machines, bag carriers, burlap sacks, push brooms, pan scrapers, sprinkling cans and shovels. The dirt collected is placed in sacks and left at convenient points to be collected by special wagons and taken to the dump in sacks, these being returned by the drivers. Sacks are used in preference to cans because of the weight, bulk and noisiness of the latter.

Machine Broom Cleaning.—All machine broom cleaning is done in batteries of two or three, preceded by sprinklers, the number of brooms in each battery depending upon the width and character of the streets to be cleaned, the average gang consisting of two machine brooms, one sprinkler, four to seven broomers, and a sufficient supply of carts or wagons to remove the sweepings, the number depending upon the haul to the dumps and the season of the year, together with the amount and character of traffic.

Squeegee Cleaning.—Squeegee cleaning is used on smooth pavements. The operation consists of batteries of two and three squeegee machines preceded by sprinklers to soften and loosen the material on the streets, the sprinklers using as much water as possible without flooding the pavement; the squeegees using just enough water to create a wash. The idea of sprinkling is to soften the surface and enable the squeegees to cleanse the streets of all slime as well as the coarser materials. The squeegees are followed by two men, who immediately sweep up the winddrows of dirt into piles, and a sufficient number of carts follow to remove the dirt from the streets.

Flushing.—Flushing machines are used only on the poorly paved streets and block pavements. The high-pressure flushing machines are usually operated singly, as most of the districts have but one flusher.

Alley Cleaning.—All alleys and streets whose width between curbs is too narrow to permit the use of machine brooms, are cleaned once each week with a hose. When such streets or alleys are required by schedule to be cleaned more than once a week, the additional cleaning is done by hand brooms.

All inlets on paved streets and alleys are cleaned as often as necessary to keep them at all times free from obstructions, this work being done by special inlet gangs consisting of three men and a sufficient number of carts.

Collection of Ashes.—The collection of ashes in the City of Philadelphia is done by contract, as is also the collection of rubbish and garbage.

Ashes from household fires are removed once each week from all buildings, two-horse wooden wagons of about 4 cu. yds. capacity being used for this purpose, and provided with canvas covers. All ashes are hauled to authorized dumps, mostly low-lands and streets requiring filling.

Waste is collected weekly throughout the entire city when a card is displayed in the window or some conspicuous place notifying the contractor that waste is on the premises. Two-horse wagons with latticed sides, holding 7½ cu. yds., are used for this purpose. The waste is hauled to dumps.

Collection of Garbage.—Collections are made daily, except Sunday, in all sections of the city, from residences. Garbage from retail groceries and fish dealers is collected daily in quantities not exceeding one bushel from each store or stand. Dead animals are also removed by the garbage contractor. The wagons used for the collection of garbage are one- and two-horse metal-bodied wagons, water-tight, and of a capacity of 1½ to 2½ cu. yds. The garbage is hauled to the plant of the contractor and disposed of by the reduction method.

Snow Removal.—The street cleaning specifications also provide, in case of snow, for the entire force of the contractor not engaged in the collection of ashes and rubbish, to be used in removing the snow, when and where directed. In order to remove the snow quickly from the central and business portion of the city, separate contracts are also entered into, in which removal of snow is paid for on the cubic yard basis and in most cases it is dumped into sewer manholes at convenient locations or in the rivers.

The following is a description of the equipment used in street cleaning work in Philadelphia:—

Hand Machine Broom.—A revolving broom encased in a sheet iron box, so constructed as to receive the materials swept up by the machine. The broom is approximately three feet in length.

Squeegee Machines.—These consist of a tank for water with a capacity of 500 gallons, a cleaning roller set obliquely, geared or chain-belted to the rear axle, having a steel axis and rubber spiral fins.

High-Pressure Flushing Machines.—A machine having a tank for water with a capacity of 500 to 700 gallons, with a gasoline pump by which the water is discharged from the nozzles, with a pressure of at least 35 pounds per square inch. The nozzles are elongated and so constructed that their direction may be readily changed and adjusted as required.

Machine Brooms.—Machine brooms consist of a roller set obliquely and geared or chain-belted to the rear axle, the roller having a wooden axis and split bamboo bristles, whose length when new shall not exceed fourteen inches from the axis. These machines are provided with dust and mud guards.

Sprinkling Machines.—Consist of a tank for water with a capacity of 500 to 700 gallons, with adjustable valves, the water being delivered by gravity pressure.

There are other appliances, such as mechanical pick-up sweepers, which, however, are not in general use. The methods of cleaning and the equipment in use today are more or less crude and capable of very great improvement, and there is ample opportunity for engineers to show their ingenuity and initiative in devising improvements over the present methods used in this country and abroad, as street cleaning is still in the experimental stage.

The following comparison closely approximates the cost of street cleaning, collection of ashes, rubbish and garbage in Philadelphia, New York and Chicago for the year 1912:—

	Area, sq. miles.	Area, sq. yds. pavements.	Population.	Total cost.	Cost per capita.
Philadelphia	129.5	17,080,545	1,610,000	$1,812,310	$1,125
New York	....134.1	26,454,553	4,743,771	8,[illegible],845	1,[illegible]4
Chicago	....191.5	18,618,155	2,307,638	2,795,077	1,211

It is very important that street cleaning work should be effective, but it should be carried on efficiently and economically as well. We must not lose sight of the fact that this work, as well as any other branch of municipal work can be overdone as well as underdone. The methods, cost, and character of cleaning in the different cities vary so much at the present time that it would appear to be desirable to carry on a country-wide investigation, with a view to determining upon more or less standard methods and degrees of cleanliness for the different characters of streets and types of pavement. The cost, in each case, would always vary with the kind and amount of traffic and labor conditions in different localities, and in making comparisons these allowances should be made. This investigation should also go into the question of the collection and disposal of garbage, ashes and rubbish, taking into consideration the proper number of collections to insure carrying on the work not only in a sanitary but an efficient and economical manner.

The following schedules of collections in some of the municipalities indicate that there is considerable diversity of opinion at the present time as to the frequency with which collections should be made:—

	Ashes.	Rubbish.	Garbage.
New York	Daily	Daily	Daily
Philadelphia	Weekly	Weekly	Daily
Chicago	3 times per week		
Washington	Weekly and semi-weekly		
Boston	3 times per week		

A great many of the methods in our cities in connection with the disposal of ashes, garbage and refuse are both crude and unsanitary, and show the lack of scientific research in connection with these matters. The present status of street cleaning work, including the collection of ashes, garbage and rubbish throughout this country is not entirely due, as has often been stated, to the newness of the problem, but to the fact that the work has been more generally under the control of men who have not had any particular qualifications for the job, and have not been in office a sufficient length of time to familiarize themselves with the work, or carry on constructive studies with a view to improving conditions. If the work is put more generally under permanent engineering organizations, much greater advance will be made within the next twenty years than has been in the past twenty years. This was illustrated by the complete change in personnel, methods and character of work inaugurated in the New York Street Cleaning Department by Col. Waring, who might well be termed "the Father of Modern Street Cleaning Methods in this Country."

Sir William Willcocks, supervising engineer of the Assouan dam, has chosen Hugh L. Cooper, the engineer who constructed the Keokuk power dam across the Mississippi, as a consulting engineer for the Egyptian Government in the construction of a new hydro-electric dam across the Nile. Mr. Cooper has specialized in the direction of long dams of small heads; and this is the problem of the engineers who are seeking to control the waters of the Nile.

THE RELATION BETWEEN THE MELTING POINT AND THE VISCOSITY OF REFINED TARS.*

By Philip P. Sharples,
Chief Chemist, Barrett Manufacturing Company,
Boston, Mass.

THE rough dependence of the viscosity of refined tars, as determined by any of the standard instruments and their melting point, has been long recognized. Many discrepancies have, however, been noted, and apparently little thought has been given to the relation between the two in making specifications.

Table I. shows a series of samples taken from refined tars made on a manufacturing scale from the same raw tars. The methods used in analysis are those described by S. R. Church in the Journal of Industrial and Engineering Chemistry, Vol. 3, No. 4, April, 1911, and Vol. 5, No. 3, March, 1913.

The melting point is the half-inch cube method in water, starting, however, at 40 deg. F. instead of 60 deg. F.

The Schutte penetrometer is, strictly speaking, not a penetrometer, but a modified melting point. An arbitrary melting point is assigned, and the time taken at the assumed melting point to force out under constant pressure a plug of the material cooled to 40 deg. F. is noted. The arbitrary melting point is so chosen on a 10 deg. F. scale that the number of seconds is as near as possible 100 deg.

The float test is the New York Testing Laboratory test. The plug was cooled to 41 deg. F. before floating. The Engler test is made under standard conditions with the exception that 100 c.c. were run off instead of 200 c.c. The reduction of the number of cubic centimeters with viscous materials allows more concordant results to be obtained and gives lower figures.

A comparison of the three melting points and the Schutte penetrometer figures show that they advance quite reguarly together. Other experiments have shown this same relation to hold true, provided the free carbon content is very nearly the same. Samples 7 and 8 may then be included in our further examination of the results without introducing undue error.

An examination of the float test shows an increasing interval between samples as we ascend in the series. Between 7 and 8 the interval is 20 sec., while between 10 and 11 the interval is 60 sec.

The results with the Engler viscosimeter show the same tendency much more accentuated. The interval between the samples 7 and 8 is 32 sec., while between samples 10 and 11 it is 96 sec. It is interesting to note that the ratio is the same as in the float test.

A more careful consideration of temperature in testing tar materials with viscosimeters would seem to be indicated. The tars are more sensitive to temperature changes than oils or asphalts, and not enough attention has been paid to viscosity changes with temperature.

The work in Table II. was undertaken to show that, although a specification was rather closely drawn for the Engler reading at 60 deg. C., it yet failed in its object in that it admitted all mixtures of tar H and tar D from 40 per cent. H to 80 per cent. H. Testing the same mixtures at 50 deg. C. shows that the same limit in the upper part of the table would confine the mixture to

*Presented before Section D of the American Association for the Advancement of Science at the Atlanta Meeting, December, 1913.

within 20 per cent., while at 40 deg. C. the same limit would confine it to within 15 per cent.

The table also illustrates again the rapid increase in the time interval as the temperature of the determination of the viscosity approaches the melting point. Thus under 60 deg. C. the space interval is 4.6 for the 50 per cent. H mixture, but this is increased to 25.6 for the 80 per cent. H mixture at 40 deg. C.

The examples that have been cited have been in series of tars of nearly uniform composition. An illustration of the effect of free carbon on the relation between the melting point and the viscosity is given in Table III. The effect of the free carbon is very marked. In the Schutte and float test the times are markedly increased. With the Engler the results are more irregular, but show a marked increase with the high carbon tar. From a physical standpoint, the increase of free carbon might be expected to have this effect. It impedes the flow of the material with increase of temperature, and in that way up to the point at which the free carbon tends to weaken the binding and lasting qualities of the tar would seem to be a desirable addition.

The inclusion of both the melting point and the viscosity in a physical examination of refined tars to be used as binders would seem to be warranted. The viscosity at 100 deg. C. compared with the melting point would give an indication of the behaviour of the tar with uniform distributors, and also an indication of its resistance to temperature changes when used on the road.

In conclusion, first, the viscosity of tars of the same composition varies with the melting point, but not in direct ratio; second, the viscosity of tars of the same melting point but of different carbon content increased with the carbon content.

TABLE I.

A Series of Samples of Refined Tar Made from Same Raw Tar.

Sample No.	Free Carbon.	Distillation. Total to 315 C.	Melting Point.	Schutte Penetrometer.	Viscosity, Engler. 100 c.c. at 100° C.	Float Test at 50 C.
5	12.1	21.8	....	29 sec. at 40° F.	94 sec.	34 sec.
7	12.0	19.2	....	108 " at 40° F.	127 "	38 "
8	14.0	16.4	....	114 " at 50° F.	159 "	58 "

Refined Tars—Relation of Viscosity to Carbon Content.

Sample.	Free Carbon.	Melting Point.	Schutte Penetrometer at 80° F.	Engler, 100 c.c. at 212° F.	Float Test at 212° F.
1	1.4	110° F.	42.2 sec.	302 sec.	158 sec.
2	14.5	109° F.	80.1 "	298 "	192 "
3	39.6	112° F.	144.9 "	739 "	337 "

The prevention of corrosion of iron in acid waters with an electrolytic method is proposed by the United States Bureau of Mines, which has made experiments with iron submerged in sulphuric-acid solutions. The metal structure to be protected is to be made the cathode of the circuit; that is, current flows from the water to it. The current density and the actual current required for protection can be calculated from experimental data on the loss in weight of the metal when unprotected under the given conditions reproduced as near as possible. This loss in weight per hour per unit area, divided by the electrochemical equivalent (weight dissolved or deposited per ampere-hour) gives the current density to be employed.. This multiplied by the actual area to be protected gives the actual current needed. For good protection, the anodes should be distributed so that the current may not return to the protected structure at one point only.

Interest is being shown at Washington in the great water power possibilities of the St. John River, running between the State of Maine and the Dominion of Canada. Oscar Fellows of Bangor, an official of the St. John River Commission, created by the United States Congress some years ago, but now defunct, told the International Joint Commission at Washington last December that the St. John River ranked close to the Niagara River for its power possibilities. The commission is consequently interested in the question whether or not the river may not be added to its jurisdiction. However, the Webster-Ashburton treaty of the 50's provided that no obstruction should be placed in the St. John River on either side. That prevents power development on the river. But it is expected that in due season Great Britain will be asked to negotiate a new treaty; since Maine and also New Brunswick would benefit from the power developed.

EUROPEAN TUNNELS.

The following is a list of the principal railway tunnels in Europe, compiled by the "Engineer," London:—

Long Tunnels in Europe.

Name	Country	Length miles	Length yds.	Summit level ft.	Opened for traffic
Simplon	Switzerland-Italy	12	458	2,313	1906
St. Gothard	Switzerland-Italy	9	564	[illegible]	1882

*Single line tunnel. †One metre gauge railway.

It is reported that no less than 40,000 h.p. will be available from the new power site reserve in Boulder Canon, 2 miles east of Las Vegas, Nev., which the Federal Government of the United States has approved.

The Madrid Ministry of Commerce has ordered plans drawn for a standard gauge railroad of double-track from the French frontier to Madrid. It is calculated to reduce the time occupied in travelling this distance from 13 hours to 7, and from Paris to Madrid from 27½ to 20 hours. It will also be the first European trunk railroad to be operated solely by electricity, and will be state-owned.

Plans for an automobile speedway at Chicago, to cost $750,000, and to rival the one at Indianapolis, have been announced; and a 500-acre tract 27 miles from Chicago, near Joliet, has been purchased. At the head of the syndicate, which purposes undertaking this construction, is J. H. Palmer of the J. H. Palmer Steel and Iron Company. A track will be built 2 miles in length and so banked at the turns as [illegible] speed of [illegible] stand of reinforced concrete will be constructed, which will seat at least 100,000 [illegible].

FUEL SUPPLY FOR THE NAVY OBTAINED FROM CANADIAN OIL SHALES.

In his report, after making a close study of the oil shale fields of Newfoundland and Eastern Canada, in which the Royal Commission appointed by the British Government is interested, Mr. Harold C. E. Spence, says: "Having regard to the importance attaching to the obtaining of large supplies of oil fuel for the navy from sources under the British flag and the comparatively few localities where such sources exist, it is considered of great national importance to preserve for the Empire, such areas of oil shales as are found to contain sufficient volatile matter to prove workable on a commercial scale; and a powerful group of financiers have associated themselves together in London to provide the necessary capital to develop such fields as Sir Boverton Redwood, the technical adviser to the Commission, passes upon.

"The Admiralty have made permanent contracts with the oil shale companies of Scotland to an extent which has caused them to increase the capacity of their plants. These Scotch shales have been worked for 50 years and produce about 60,000,000 gallons of oil per annum with valuable by-products of sulphate of ammonia, etc. The value of oil shales compared with oil wells, is on account of the assured permanency of the output, as on account of the deposits lying almost identically in the manner of coal deposits. The tonnage can be measured approximately and the contents gauged by a system of bore holes, whereas in oil wells there is no way of arriving at the permanency of the flow, some wells and fields becoming exhausted in a few months. In Newfoundland and other places in Eastern Canada, some billions of tons of payable oil shales are assured; and some hundreds of millions of tons are known to contain a far greater percentage of oil to the ton than the successful Scotch fields. There is, therefore, a reasonable hope of a very important industry being inaugurated in the extraction and the refining of oil and the by-products from these shales in the near future."

METHODS OF CHECKING THE ANEROID.

An aneroid barometer is the fastest and most easily portable device for determining elevations. But even during constant weather conditions, it is subjected to changes in pressure equivalent to 50 or 100 feet of elevation, the pressure becoming lowest in the afternoon. It is subject also to the more irregular changes caused by the passage of the cyclonic and anticyclonic pressure areas. (Econ. Geol., October, 1913.) These discrepancies are partly overcome by checking at intervals over points of known elevation, by having a second observer record the readings of another instrument kept fixed, and by keeping the instrument fixed occasionally for short periods of time and noting the rate of change of the readings. A much neater and more satisfactory method of correcting is to use the barograph or recording barometer. This is made in easily portable form and gives an accurate paper record of pressure changes. The instrument can be left at headquarters when a day's work is begun. By noting the times of all readings taken with the field barometer and comparing them with the barograph record for the time in question, the proper correction due to atmospheric changes can be obtained.

Messrs. Ross and Macdonald, architects, have moved their western office from 928 Union Bank Building, to 506 Tribune Building, Winnipeg.

The construction of tank cars, specially equipped for fire fighting, is a new departure on the part of the C.P.R. They are, in general, of the standard construction. They have been built to the designs of the company by the American Car Company; and the idea is to operate them in pairs. Apart from the end arrangement of the auxiliary equipment, they are of identical construction. Each car carries a tank of 8,438 imperial gallons, and on the end of each car there is a 20 by 10 inch duplex fire pump, using steam from the locomotive boiler. The corresponding end of the other car has a rack construction on which can be carried 6,000 feet of fire hose. The car is designed for weight capacity of 100,000 pounds, so standard 50-ton trucks are employed. These tank cars have done good service in the United States.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of
CIVIL, STRUCTURAL, RAILROAD, MINING, MECHANICAL, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

THE CAUSE OF RAIL CORRUGATION.

The corrugation of rails has become a rather serious problem in the operation of electric traction. There is considerable doubt as to whether the rail of to-day is sufficiently hard and tough in quality for its work. Investigations organized by numerous associations in various countries have not discovered a solution of the trouble and opinions differ widely as to its cause. Whether modern methods of manufacture, involving as they do the use of large ingots, rapid rolling at high temperature, and consequent absence of homogeneity are not themselves to blame to a large extent for the trouble which the electric railway engineer experiences in the matter of rail corrugation is a question. Of course, experience may have some part to play and it is possible that the railway engineer, after many years of steam railway experience, fails to some extent to grasp the fact that conditions of electric traction differ widely from those which are obtained in ordinary railway work.

In a paper which he read recently before the Institution of Civil Engineers of Great Britain, Mr. S. P. W. Sellon gave it as his opinion that the steel rail now used was not hard enough or tough enough for its work. The use of wheels of small diameter was evidently severe on the rails, but the conditions of electric traction forbade alteration, and the alternative was to find the material which would not yield to the action of the wheels which served to cause corrugation. He expressed his belief that rails with a high percentage of carbon are essential and that they resist corrugating effects as well as ordinary wear.

In his description of the general character of corrugation, Mr. Sellon states that the crests which develop have the appearance of planished or cold-rolled steel and that they are relatively hard and refractory to acid, while the hollows were dull and showed lateral detrusion and pitting. He drew the conclusion that the crests were cold-rolled and the hollows consisted of surface which had been crushed due to the vertical loads imposed by the wheels oscillating about the elastic limit of the steel in compression. It was pointed out that at ordinary speed the usual pitch of the corrugations corresponded with a frequency of about 100 feet per second.

Investigation seemed to show that a comparatively small increase in the compressive strength of the steel would prevent the particular kind of wear which created corrugation in the rail. Mr. Sellon, therefore, suggested that steel with an ultimate strength of 50 or 60 tons per square inch should be used to successfully resist the destructive stresses, the steel at the same time to be devoid of a high degree of ductility. The British Standard prescribes an ultimate tensile strength of 40 tons per square inch, while the actual wear of rails is apparently somewhat in excess of this strength.

The minimum pressure required to produce surface crushing and flowing is apparently in need of early determination. Clauses in rail specifications governing mechanical qualities should obviously bear a direct relation to the stresses which the rail will be called upon to resist. They should be clearly defined to ascertain what portion of rail corrugation is due to abrasion caused by the slip and what to the relative movement between the areas of contact of the wheel-tread and the rail-table in producing a grinding effect. More knowledge on these subjects will assist in finding a rail material that will withstand the actions producing the above defect.

NEW GOVERNMENTAL DEFINITION OF "ENGINEER" IN BRITISH COLUMBIA.

The British Columbia members of the Canadian Society of Civil Engineers have recently shown considerable activity in endeavoring to get the status of the Engineer recognized by the Provincial Government, and, in view of much new legislation involving large engineering projects, several influential deputations of the members, headed by Mr. F. C. Gamble, Chief Engineer of the Department of Railways, and Mr. G. R. G. Conway, Chief Engineer of the British Columbia Electric Railway Company, Limited, the respective chairmen of the Victoria and Vancouver Branches, met the Premier, Sir Richard McBride and the Executive Council and laid before them very strongly the views of the Western members.

It was pointed out that in numerous Acts of Parliament the definition of an Engineer was extremely unsatisfactory. One example given was quoted from the "Ditches and Water Courses Act, 1907," where an Engineer is defined as follows:—

"Engineer means Civil Engineer, Provincial Land Surveyor, or such a person as any municipality may deem competent and appoint to carry out the provisions of this Act."

The effect of this definition in one instance in British Columbia was the temporary appointment by resolution of the Municipal Council of a small contractor to sign plans, and the deputation pointed out to the Ministers that there was nothing in the Act to prevent a Municipal Council from appointing a gardener, blacksmith or carpenter to carry out the duties of the Act as Engineer.

The deputation were accorded a very sympathetic hearing from the members of the Government, and many private members supported their proposals.

Subsequent to the interviews with the Government, a petition was sent to the Premier, signed by every leading Engineer in the Province, asking that the word "Engineer" should be defined in the new Water Act as follows:—

"Engineer means an Engineer of the Water District, who shall be a Civil Engineer who is a member of the Canadian Society of Civil Engineers, or a member of the Institutions of Civil Engineers of Great Britain or of Ireland, or a member of a Civil Engineering Society of equal rank in the British Empire or any foreign country."

This definition was accepted by the Minister of Lands, Hon. W. R. Ross, who, however, felt that while entirely recognizing the principle of the definition, and expressing himself in hearty accord with the objections of the members of the Canadian Society, that special circumstances might arise in which he might be hampered by too strict an observance of the definition. He, therefore, suggested the addition of the following words, which was mutually agreed upon, and now, together with the foregoing, forms part of the Water Act of 1914:—

"But the foregoing definition shall not limit the power of the Lieutenant-Governor-in-Council or the Minister to appoint to any position created under this Act, any person who is, in his opinion, competent to fill such position."

The Western members feel that they are to be congratulated upon the success of their efforts, and hope during the next session to have a similar definition incorporated in the Municipal Act, the Railway Act, and other Acts dealing with engineering undertakings.

LETTER TO THE EDITOR.

Jointing of Water and Gas Mains.

THE spigot and faucet, or the hub and spigot joint, is universally adopted for jointing water and gas mains, and the old method of caulking the joints with spun yarn and lead is still in use everywhere on the globe. The lead melting pot still holds the field.

The reasons for sticking, the world over, to the old approved hub and spigot joint, are various: The easy method of laying; the standardization of fittings, etc., etc.; and last, but not least, the adaptability of the joint to absorb, to a sufficient extent, the contractions and expansions occurring in the mains. There can be little doubt that the hub and spigot joint is, so far, the best joint for municipal gas and waterworks, where the pressure does not exceed 200 lbs. per square inch, provided that the socket and spigot are made strong enough to allow the yarn and lead to be driven home in a proper way; and here lies the weak point about which many complaints are received.

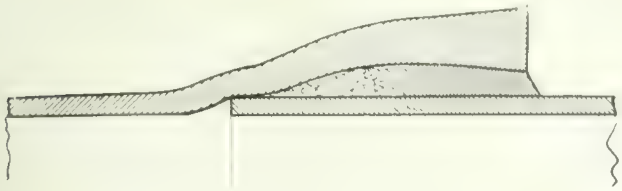
In the case of cast iron pipes, the material is brittle and liable to breakages, i.e., the caulker must not try to strike the lead ring too hard, or else he runs the risk of breaking the socket. The caulking of cast iron pipes requires careful handling, and skilled labor, which is not always at hand in this country.

In the case of steel pipes, the socket is commonly formed by expanding the pipe end. It is quite patent that this is not a very satisfactory process, as the pipe wall is reduced in thickness when expanded, with the result that that part of the pipe which should be strongest, becomes weakest. Manufacturers have been trying to overcome this difficulty by doubling the end of the socket, or by having an iron band shrunk on to the socket end. However, this method of reinforcing has proved to be insufficient, as—especially in the case of the smaller sized pipes—the socket will vibrate during the caulking process; or is liable to deforming, or even splitting, thus causing unreliable or even leaky joints right from the start. Sockets of this kind have given very little satisfaction, and the many complaints have caused manufacturers of steel pipes to look for improvements in this direction.

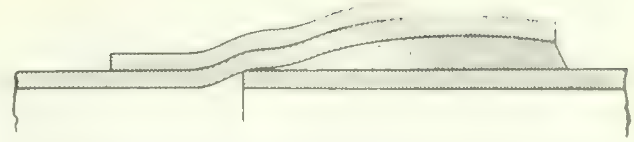
One of the latest proposals is to weld the sockets by the oxy-acetylene process. This experiment, however, cannot be looked upon, seriously, as solving the problem. This idea, which provides for continuous mains, would do away with the principal reason for using hub and spigot joints; i.e., it would not allow of expansion and contraction; and, as iron or steel mains are liable to these movements, something would have to go, no matter how good the joints might be. Furthermore, the welding would be a very big item in the laying expenses, and requires an elaborate outfit, quite apart from the fact the welding of the joints will be very difficult in places. This experiment, therefore, can be discarded as being not practicable.

A strong and solid socket, which requires no delicate handling, and allows of driving home the yarn and lead in such a manner as to make sure of a tight and lasting joint, remains the only solution; i.e., the socket should be reinforced in such a way as to make vibration or deforming and splitting impossible; and the packing space must be of ample depth and sufficient width. The writer inspected, last year, pipes used by the British Columbia Electric Railway Company (Vancouver Gas Company),

which were of a peculiar design. The smaller sizes had a socket reinforced as illustrated hereunder:—



On the larger sizes the sockets were reinforced by a shrunken-on ring, covering the whole length of the socket, and part of the pipe, as follows:—



These sockets looked assuringly strong and well designed, and the writer understands that the joints have given satisfactory results.

HYDRAULIC ENGINEER.

Montreal, March 21st, 1914.

C.N.O.R. BRIDGE OVER EAST STURGEON RIVER.

THE bridge across the East Sturgeon River, at mileage 250 from Ottawa, on the Ottawa-Capreol line of the Canadian Northern Ontario Railway, has just been completed. The accompanying drawings, showing the bridge in plan and elevation, together with the photographs, give some idea of its general design and methods of erection.

The deep and swift current which the river possesses at this point, together with the fact that it is subject to a rapid rise of several feet, rendered the construction of this crossing somewhat difficult. Accessory to these conditions the bridge is built at an angle of 60° with the centre line of flow of the stream.

Foundation work was rendered difficult owing to the presence of huge boulders and rock in deep water. In order to avoid, as far as possible, the necessity of constructing costly falsework for a truss, it was decided to use long deck plate girder spans. The crossing comprises four of them, two 130-ft. deck plate girder spans across the stream and one 80-ft. span of similar type at each end. After the contract had been awarded, however, the Canadian Bridge Company decided that it would be preferable to construct falsework over the stream, notwithstanding the fact that the contract had been awarded for the long spans with the expectation that only a small amount of falsework would be necessary.

The method of erection adopted was to unload the girders on blocking near the site and to completely rivet each pair before lowering them to the line of track. Two additional rails had been laid about 12 in. outside of the standard gauge rail, which gave a sufficiently wide and satisfactory base. Five bolsters of 14-in. x 14-in. timber, with steel shoe plates, were attached to the underside of the girders resting upon the rails, the latter being well lubricated. In this way a set of girders was moved through a distance of about 600 ft. over the approach

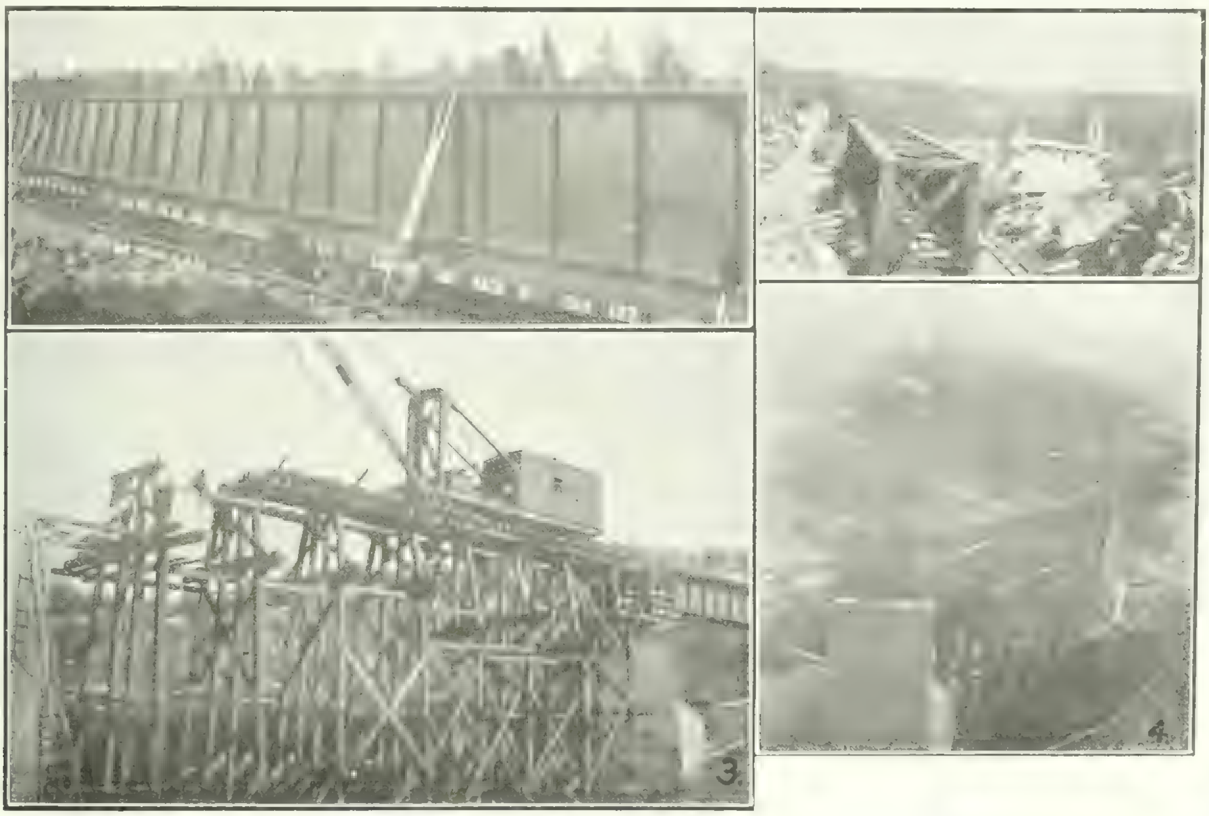


Fig. 1.—A 130-ft. Girder on Cars. Fig. 2.—Span (130 ft.) assembled.
Fig. 3.—Construction of Falsework. Fig. 4.—A 130-ft. Span being moved into position over piers.

and falsework in the stream, and into position over the piers. The power used for moving the girders over the falsework was obtained from a derrick car engine, a three-quarter-inch cable with two sheave blocks being used for the purpose. The girders were moved about 100 ft.

Fig. 5.—One of the 130-ft. Deck Plate Girder Spans Resting on Blocking on Piers, over Falsework.

without adjusting the blocking and cable, the whole operation of moving these over 600 ft. taking about one and one-half days. The high blocking over the piers, being at a height of about 35 ft. above water level, made the process of lowering the girders somewhat slow. To prevent any undue stress being brought on any of the parts of girders a harness was made of timber, which served the purpose quite well. One end was lowered 14 inches at a time, the lowering being accomplished by the use of four 40-ton jacks. The weight of each 130-ft. span is approximately 280,000 lbs. The 130-ft. girders are spaced 9 ft. centre to centre with ties 10 in. x 12 in. x 14 ft. The bridge is designed for Class "Heavy" Loading, Dominion Government Specifications, 1908. The total weight of the steel in the crossing is 745,000 lbs. The total amount of concrete used in the substructure was 1,725 cu. yds.

The complete structure cost in the neighborhood of $70,000. The Canadian Bridge Company, Walkerville,

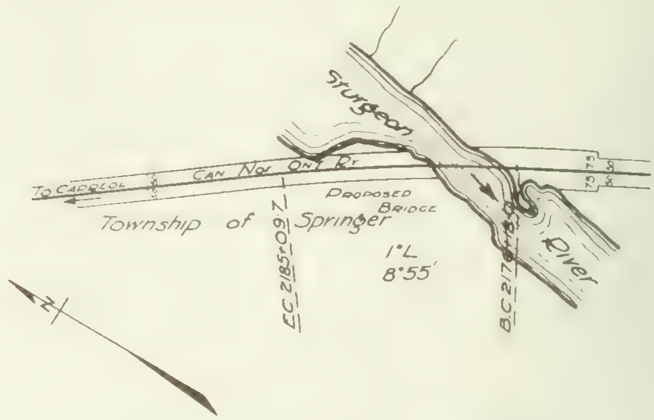

Fig. 7.—Showing Bridge Location.

was awarded the contract for the furnishing and erecting of the superstructure, which was delivered and erected without mishap, despite the difficulties which the site presented. The substructure was built by R. S. and J. H. Henderson, sub-contractors under The Angus Sinclair Company. Mr. J. C. Smith had charge of the erection for the Canadian Bridge Company. The work was carried out under the direction of A. F. Stewart, Chief Engineer, Canadian Northern Ontario Railway, and W. P. Chapman, Engineer of Bridges, Mackenzie, Mann & Company, Limited. We are indebted to the latter for the description of this work and the photos accompanying it.

HISTORY OF THE CONSTRUCTION OF BROKEN STONE ROADS.*

By R. L. Morrison,
Graduate Student in Highway Engineering, Columbia University, New York City.

THE first broken stone roads were built in France in 1764 by Pierre Marie Jerome Treseguet, who was then Chief Engineer of the District of Limonges. Previous to that time there were few improved roads in France. The Corps de Ponts et Chaussees had been organized in 1716, the year of Treseguet's birth, but most of the roads, according to a writer of the time, were in a "state of nature or worse." Where road improvement was attempted at all it was done by what was known as the Roman method. An excavation was made, forming a flat sub-grade, and on this was placed the foundation of the road, which consisted of two or more layers of large, flat stones. This foundation was eighteen feet wide and about ten inches deep, and was covered with a layer of small stones, which were spread and then beaten down and broken in place with hammers. The surface was finished with a thin layer of stones smaller than the underlying material and consolidated by traffic. The total thickness of the road was usually 18 to 20 inches at the centre and about 12 inches at the sides. While these roads, when completed, contained more or less broken stone, it was not an essential feature of their construction.

The large amount of material used made these roads very expensive to build, and, owing to the lack of proper maintenance, they were soon cut by deep ruts. All road work was done by means of the corvee, a system of compulsory labor, which was available only twice a year, so that when repairs were made, large quantities of stone were required.

In the District of Limonges the corvee was abolished in 1764, so cheaper methods of construction and maintenance became necessary, and this necessity was met by Treseguet with the broken stone road. His method of construction was a modification of the Roman method, and is described by the originator as follows: "The bottom of the foundation is to be made parallel to the surface of the road. The first bed on the foundation is to be placed on edge, and not on the flat, in the form of a rough pavement, and consolidated by beating with a large hammer, but it is unnecessary that the stones should be even, one with another. The second bed is to be likewise arranged by hand, layer by layer, and beaten and broken coarsely with a large hammer, so that the stones may wedge together and no empty space may remain. The last bed, three inches in thickness, is to be broken to about the size of a walnut, with a small hammer, on one side of a sort of anvil, and thrown upon the road with a shovel to form the curved surface. Great attention must be given to choose the hardest stone for the last bed, even if one is required to go to more distant quarries than those which furnish stone for the body of the road; the solidity of the road depending on this latter bed, one cannot be too scrupulous as to the quality of materials which are used for it."

Treseguet was also the first to propose a system of continuous maintenance, and fought with energy the old method of intermittent repairs.

In 1775 he was made Inspecteur General des Ponts et Chaussees. In the same year the corvee was abolished in all of France, and the following year Treseguet's method of construction was officially adopted.

England failed to profit by Treseguet's invention, and at the beginning of the nineteenth century the methods of road improvement and repair were similar to those discarded in France a generation before. In building a road a trench was dug and large masses of stone put into it. Over this foundation were spread thick layers of broken stone, and the surface was finished with an extremely high crown, approaching a semi-circle in form. This crown was composed of earth, rushes, stones and various other materials, and was covered over with a small quantity of gravel. As a result all traffic was forced to keep to the centre of the road, the sides being dangerous.

Deep ruts were formed, which retained water and mud, and the road soon became impassable. On account of robbers and the bad state of the roads wills were always made previous to undertaking a long journey by stage-coach.

The man whose skill as a road builder changed this deplorable state of affairs, and whose name has been generally applied all over the world, in the form of noun, adjective and verb in connection with broken stone road construction, was John Loudon McAdam, who was born at Ayr, Scotland, in 1756. Much of his youth was passed in the United States but he returned to Scotland in 1783 and became road trustee and manager of a district in Ayrshire.

Between the years 1798 and 1814 McAdam travelled about 30,000 miles over the roads of Great Britain making investigations, and during this time he originated the system of road-making now known by his name. In 1815 he was appointed surveyor of roads in Bristol, and there his system of construction and repairing reached its highest development.

This system was founded upon the theory, as stated by McAdam, that "The roads can never be rendered perfectly secure until the following principles be fully understood, admitted, and acted upon, namely, that it is the native soil which really supports the weight of traffic; that while it is preserved in a dry state, it will carry any weight without sinking, and that it does, in fact, carry the road, and the carriages also; that this native soil must previously be made quite dry, and a covering, impenetrable to rain, must then be placed over it, to preserve it in that dry state; that the thickness of a road should only be regulated by the quantity of material necessary to form such impervious covering, and never by any reference to its *own* power of carrying weight."

He severely condemned the use of large stones under any circumstances, in any part of the road, and said that every stone exceeding one inch in any dimension was mischievous.

Regarding the body of the road, the report of a special committee of parliament in 1823 says: "It appears that Mr. McAdam first directed the public attention to this important fact, that angular fragments of hard materials, sufficiently reduced in size, will coalesce or bind, without other mixture, into a compacted mass of stone nearly impenetrable to water, which, being laid almost flat, so as to allow of carriages passing freely upon all parts of the road, will wear evenly throughout, not exhibiting the appearance of ruts or of any other inequalities."

McAdam wrote several essays and reports on highways, and gave the following directions for road-building: "The first operation in making a road should be

*Presented before Section D of the American Association for the Advancement of Science at the Atlanta Meeting, Dec., 1913.

the reverse of digging a trench. The road should not be sunk below, but rather raised above, the ordinary level of the adjacent ground; care should at any rate be taken that there be sufficient fall to take off the water, so that it should always be some inches below the level of the ground upon which the road is intended to be placed; this must be done, either by making drains to lower ground, or if that be not practicable, from the nature of the country, then the soil upon which the road is proposed to be laid must be raised by addition, so as to be some inches above the level of the water.

"Having secured the soil from *under* water the road-maker is next to secure it from rain water, by a solid road, made of clean, dry stone, or flint, so selected, prepared, and laid, as to be perfectly impervious to water; and this cannot be effected unless the greatest care be taken, that no earth, clay, chalk, or other matter, that will hold or conduct water, be mixed with the broken stone; which must be so prepared and laid, as to unite by its own angles into a firm, compact, impenetrable body. Nothing is to be laid on the clean stone on pretence of *binding*."

As a rule the metal on McAdam's roads was 16 feet wide, with 6-foot shoulders of softer materials. The depth of the metal was from 7 to 10 inches, and the roads were usually built in three layers. The crown was 3 inches for a width of 18 feet.

The sizes of broken stone used he described as being of six ounces weight, and he always made his surveyors carry a pair of scales in their pockets to use in testing the sizes.

McAdam sometimes used gravel instead of broken stone, but it appears that this was done usually in cases where local conditions, including legal restrictions, made the use of broken stone impracticable. In his directions for road work, in 1811, he said: "Every road is to be made of broken stone," and in testimony before a committee of parliament in 1819 he said: "Now the principle of road-making I think the most valuable, is to put broken stone upon a road, which shall unite by its own angles, so as to form a solid, hard surface; and, therefore, it follows, that when that material is laid upon the road, it must remain in the situation in which it is placed without ever being moved again; and what I find fault with putting quantities of gravel on the road is, that before it becomes useful it must move its situation and be in constant motion.

"In digging the gravel near London, and places where there are vast quantities of loam, and that loam adhering to every particle of the gravel, however small, I should recommend to leave the very small or fine part of the gravel in the pits, and to make use of the larger part, which can be broken, for the double purpose of having the gravel laid on the road in an angular shape, and that the operation of breaking it is the most effectual operation for beating off the loam that adheres to the pieces of gravel."

It is obvious that this "gravel in angular shape" was really broken stone, and it is possible that in other cases where McAdam referred to gravel he meant broken gravel.

Where the substratum was unsound the usual custom was to cover it first with a layer of faggots and brush. On this was placed a layer of large, flat stones, then a layer of smaller stones, and finally eight or ten inches of broken stone. In such cases McAdam, however, used no faggots, large stones, or other special foundation, and he said that he would actually prefer a soft sub-grade, or even a bog, for his ordinary roads. He claimed that a road on a hard foundation was quickly worn out, but that on the softest ground the foundation never sank.

Methods of repairing roads were carefully studied by McAdam, and he gives the following directions for this work:—

"No addition of materials is to be brought upon a road, unless in any part of it be found that there is not a quantity of clean stone equal to ten inches in thickness.

"The stone already in the road is to be loosened up and broken, so as no piece shall exceed six ounces in weight.

" . . . The stones when loosened in the road are to be gathered off by means of a strong, heavy rake, with teeth two and a half inches in length, to the side of the road, and there broken, and on no account are the stones to be broken on the road.

"When the great stones have been removed, and none left in the road exceeding six ounces, the road is to be put in shape and a rake employed to smooth the surface, which will at the same time bring to the surface the remaining stone, and will allow the dirt to go down.

"When the road is so prepared, the stone that has been broken by the side of the road is then to be carefully spread on it; this is rather a nice operation, and the future quality of the road will greatly depend on the manner in which it is prepared. The stone must not be laid on in shovels full, but scattered over the surface, one shovel full following another and spreading over a considerable space.

" . . . The object to be aimed at is to keep the natural soil dry, and this must be done both by defending it from ground water, and from that which falls from above. In the knowledge of the measures requisite to effect those objects consists the whole science of road-making."

McAdam turned his attention not only to methods of construction and maintenance, but to questions of road administration, legislation, and finance. He was engaged as general surveyor by many of the road trusts of England and Scotland, and his system proved so beneficial that he built up a world-wide reputation. In 1820 his work began to attract attention in France, and in 1830 his system was officially adopted in that country. He died in 1836.

It is very probable that McAdam was not actually the inventor of the method of construction he employed. The Westminster Review in 1825 states that this system had long been in use in Sweden, Switzerland and other countries, and in his testimony before the Parliamentary Committee in 1819 one John Cripps, Esq., said: "I had an opportunity of observing in Sweden that the roads were more beautiful than any I ever beheld; they are formed in the same manner as by Mr. McAdam, the materials broken extremely small. The material is the best in the world, as it is rocks of granite; and so well do they understand the necessity of breaking them small, that you never behold, throughout Sweden, a fragment of granite larger than the size of a walnut, for the purposes of the road. To the eye the roads appear perfectly flat; but upon trial by the spirit level there is a slight degree of convexity."

Another road builder, whose fame is exceeded only by that of his contemporary, McAdam, was Thomas Telford. He also was a Scotchman; he was born one year after McAdam and died two years earlier (1757-1834). He received the rudiments of an education in the parish school of Westerkirk, learned the trade of a mason, and later studied architecture in Edinburgh and London. It was as a bridge builder that he first became widely known. In 1787 he was appointed Surveyor of Public

Works in Shropshire, where he built many fine bridges and excellent roads. His greatest work was in the Highlands of Scotland, where he was sent by the Government in 1802 to report on the best means of developing the country. He recommended an extensive road system, and under his direction nearly a thousand miles of gravel road were built and more than a thousand bridges. This work extended over a period of eighteen years and cost 2¼ million dollars. Telford's specifications for these roads are given by Aitken, and they include minute details of parapet walls, drains, etc.

Apparently the first broken stone road built by Telford was that between Glasgow and Carlisle. This work was done in 1816, and involved extensive reconstruction of the old road. The distance was reduced from 102 miles to 93 miles, which necessitated the entire reconstruction of 69 miles of the road and the building of fifteen new bridges. The maximum gradient of the new road was 1 in 30. The cost, exclusive of bridges, was $5,000 a mile.

It was specified that "the breadth was to be 34 feet between the fences, 18 of which were to be metalled, and the remaining 8 feet on each side to be covered with gravel.

" . . . The metalling to consist of two beds or layers, viz., a bottom course of stones, each 7 inches in depth, to be carefully set by hand, with broadest end downwards, all cross-bonded or jointed, and no stone to be more than 3 inches wide on the top. These stones to be either good whinstone, limestone, or hard freestone; the vacuities between to be carefully filled with smaller stones packed by hand, so as to bring the whole to an even and firm surface.

"The top course or bed to be 7 inches in depth, to consist of properly broken stones, none to exceed 6 ounces in weight, and each to pass through a circular ring 2½ inches in diameter in their largest dimension. These to be of hard whinstone, the quality of both bottom and top metal to be determined by the inspector. In every 100 yards in length on each side of the road, upon an average, there was to be a small drain from the bed of the bottom layer to the outside ditch, as directed by the inspector. When the height of the embankments exceeded 3 feet, they were to stand from 1 to 3 months, in proportion as they increased in depth, as determined by the inspector. Over the upper bed, or course, of metal to be a binding of gravel of 1 inch in thickness upon an average; the cross-section of the finished roadway to have a curvature of 6 inches; in the middle 18 feet, and from that on each side a declivity at the rate of half an inch in a foot, to within 18 inches of the fences; the remaining space of 18 inches to have a curvature of 3 inches, making, in all, about 9 inches on each side below the finished roadway."

Cross-drains, nine to every mile, were to be placed under the road, and were to be 18 inches wide and from 16 to 22 inches high. The manner of contructing these drains was carefully specified.

The principal difference between Telford's form of construction and that of Treseguet was that Treseguet made his sub-grade parallel to the finished surface of the roadway, while Telford used a flat sub-grade. McAdam differed from both in omitting the large foundation stones.

On a portion of the Highgate Archway Road Telford used a 6-inch concrete foundation, composed of one part Roman cement to eight parts of washed gravel and sand. Transverse channels were cut in the surface four inches apart, and inclined toward the sides. These channels were for drainage, and also served to keep the broken stone in place on the concrete.

This road was a great success, and on another road a similar foundation of a 1 to 4 lime and gravel mixture was used. This was covered with 6 inches of broken stone, built in two layers. Wherever used this method was successful, and ten years after Telford's first experiment in 1828, Thomas Hughes wrote: "I am decidedly of opinion that this material, if generally adopted as a foundation for roads, will effect one of the greatest improvements that has for many years been presented to the notice of the public."

Most of the stone-breaking for the McAdam and Telford roads was done by women, old men, and boys.

Edgeworth wrote in 1817: "Attempts have been made some years ago to break limestone for roads by the force of horses, wind, and water. Stampers, shod with iron, and raised by proper millwork, were employed, and they were let to fall upon blocks of whinstones. These mills . . . crushed the stone to dust rather than to fragments if lighter stampers were employed, they frequently failed to break the stone. Feeding the mill was also found difficult and dangerous."

Successful experiments with a steam-driven roller crusher were made previous to 1844.

Quarrying was done with crowbars and picks until about 1840, when blasting began to be used.

The spirit level was first used on highway work in 1790, and the later roads were often carefully surveyed.

In 1817 Philip Clay invented "a harrow which is intended to scarify the uneven part of the road." Little improvement was made in scarifiers until comparatively recent years.

Road templets were in use in 1838.

The machine which has had the greatest influence upon methods of road construction is the roller. In 1619 one John Shotebolte wrote of using "land stearnes, scowrers, trundlers, and other strong and massy engines," but the first practical horse-roller was made in France in 1787. Thirty years later the roller was introduced into England, but it was not widely used in that country until 1843, when Sir John Burgoyne wrote a pamphlet on the subject of road-rolling.

The first steam roller was invented in France in 1859, and their use soon spread to other countries.

France has always been the leader in road-building, and the French method of construction, as described in 1843, contained most of the essential elements of the modern road. These roads were from 4 inches to 8 inches in thickness, and when over 4 or 5 inches thick were built in two layers. The road was thoroughly watered and rolled, first with an empty roller weighing 3 tons, then with the cylinder filled to weigh 6 tons, and finally with the roller loaded to a weight of about 10 tons.

The stone was broken to a maximum size of 2½ inches. The smallest *debris* of broken stone was saved and spread on top, with water, at intervals during the rolling.

English writers a generation later had few improvements to suggest, and gave the above as the best practice known, except for minor changes due to the introduction of the steam roller and the improvement of other road machinery.

In fact, an attempt to trace the history of further development of construction methods would be more properly classed as a discussion of modern practice.

No allusion has been made to American roads, because, during the period covered, the improved roads of

this country were very much like the famous snakes of Ireland—noted for their absence. Two events may be mentioned, however, as being of special importance in the history of broken stone roads in the United States. They are the building of the first road of this type, the Lancaster Turnpike, in 1792, which for several years was simply a gravel road; and the granting of the first patent for a steam roller in 1873.

COST OF LOS ANGELES AQUEDUCT.

An article dealing with the completion and operation of the Los Angeles aqueduct was published in *The Canadian Engineer* for January 9th, 1913. Recently some interesting figures have been published in the last annual report of the aqueduct organization and appear below. It would appear that the undertaking has been completed none too soon as the report describes the rapid increase in territory served by the city plant and the difficulties which the municipalities taken in have had in supplying themselves.

The report gives all the items of the cost as follows:

The first issue of Aqueduct bonds, expended in preliminary surveys, purchase of lands in and above Owens Valley, water rights, rights of way, etc. ....$	1,500,000.00
The second issue, $23,000,000, expended in construction of aqueduct, minus $61,000 on hand and $700,000 of salvage	22,239,000,00
Aqueduct liabilities unpaid as hereinbefore set forth	490,000.00
	$24,229,000.00
Paid out of Water Revenue Fund as follows:	
One-half of Mr. Mulholland's salary during period of construction of aqueduct..$	52,500.00
Purchase price of San Fernando Reservoir site	126,000.00
Cost of San Fernando dam to date	319,785.73
Interest on Aqueduct bonds paid by tax moneys, up to May 12, 1913	3,110,057.93
Making total cost of the aqueduct ....$	27,837,343.66

The original estimates, represented by the $24,500,000, have been exceeded some 3⅓ million dollars, including the payments of interest. Work not included in those original estimates includes about a million dollars spent in additional cover over the aqueduct, and the San Fernando reservoir work in the table, in all some $1,500,000.

TREATMENT OF TITANIFEROUS ORES.

Many deposits of titaniferous magnetite, some of them very large, have attracted considerable attention as possible sources of iron. With present furnace practice, however, reduction of ores carrying more than a small percentage of titanium is difficult and expensive, and consequently such ores are refused by the furnaces. In its endeavor to bring about the utilization of undeveloped mineral resources in the United States, the Bureau of Mines completed an investigation in relation to the treatment of titaniferous iron ores by magnetic concentration. The results of this investigation, which was conducted by J. T. Singewald, Jr., have been transmitted for publication in bulletin form.

An investigation of the possibility of utilizing titaniferous magnetites in the electric furnace for the direct manufacture of iron-titanium alloys, such as being used in making special grades of steel, is to be undertaken by the bureau.

MUNICIPAL ELECTRIC POWER STATIONS IN THE UNITED STATES.

Preliminary figures of the forthcoming report on the municipal central electric light and power stations of the United States have been given out by Director Harris of the Bureau of the Census, Department of Commerce Municipal stations are those operated under the ownership of municipalities or other local governments. They do not include electric plants that were idle or in course of construction.

As a rule, no cash income is derived by municipal stations for electrical energy used for lighting streets and public buildings, and in order that the income shown may approximate the total consumption and sale of electric current by these stations the schedule required that the income for service of this character should be estimated on the basis of what would have been charged for similar service by commercial companies in nearby localities. The number of persons employed may fall short of the total number actually engaged in work in connection with the operation of the electric stations, because the services of employees for the electrical work often are not required for long or continued service, and they are reported with that branch of municipal work with which they are chiefly employed.

The figures as presented for the United States show substantial gains for the decade 1902-1912. The number of stations increased from 815 in 1902 to 1,562 in 1912, or 92%; the total income for 1912 amounted to $23,218,989 as compared with $6,965,105 in 1902, or an increase of 233%; the total expenses for 1912 amounted to $16,917,165 as compared with $5,245,987 in 1902, or an increase of 222%. The total number of persons employed numbered 7,940 in 1912 as compared with 3,417 in 1902, or an increase of 132%; the total horse-power of the power plants was 559,328 in 1912 as compared with 160,028 in 1902, or an increase of 249%; the horse-power of the water wheels increased from 11,218 in 1902 to 130,261 in 1912, or 1,061%; the output of stations in 1912 was 537,526,730 kw. hours as compared with 195,904,439 in 1902, or an increase of 174%. The estimated number of arc lamps wired for service was 91,851 in 1912 as compared with 50,795 in 1902, or an increase of 81%; all other varieties of lamps wired for service, numbered 7,057,849 in 1912 as compared with 1,577,451 in 1902, or an increase of 347%; the horse-power capacity of the stationary motors served with electric current was 164,291 in 1912 as compared with 3,324 in 1902, or an increase of 4,843%.

There was an increase of 310 stations in 1912 as compared with 1907, accounted for as follows: New stations, 301; from commercial to municipal stations, 106; from municipal to commercial, 80; and 17 stations reported in 1907 that were out of business or not in operation in 1912.

A comparison of the C.P.R. tunnel at Roger's Pass through the Selkirk with other tunnels of world-wide fame is interesting. The greatest tunnel in the world is the Simplon Pass tunnel, which is 13 miles long. Then comes the St. Gothard and the Mont Cenis. The longest tunnel in the United States is the Hoosac, which is 4 miles long. The C.P.R. tunnel in the mountains will be the biggest thing on this continent and the most difficult accomplishment. The C.P.R. has one great advantage over any other system in respect of the operating of the trains through the tunnel. It will make its own power from the electric energy stored in the heart of the mountains.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

CONTENTS.

BOOK REVIEWS.

Village Electrical Installations.—By W. T. Wardale. Published by Whittaker and Company, London and New York. 80 pages and 12 illustrations; 5⅛ x 7½ in.; cloth. Price, 58 cents net.

This book is written in very simple, non-technical language, and would no doubt prove interesting and useful to the members of a village council who wished to get a general idea as to what might be done in the way of providing electric lighting in their district.

The author rightly insists on the services of an engineer being requisitioned before proceeding with any particular scheme. On the whole, the book would not be of much use in this country owing to the entirely different practices obtaining here in electrical work as compared with England. The illustrations are good and the information given is, so far as it goes, accurate.

The "Mechanical World" Pocket Diary and Year Book for 1914.—Published by Emmott and Company, Limited, 65 King Street, Manchester, Eng. Norman and Remington, 108 North Charles Street, Baltimore, U.S.A., American selling agents. Price, 25 cents.

It speaks well for the popularity of this book that it is now in its twenty-seventh year of publication. Although no doubt somewhat more useful in Great Britain than on this side of the Atlantic, it will be found a handy reference book even here, as it contains a great deal of useful and reliable information.

Apparently since last year arrangements have been made for its sale on this continent as indicated above, and its low price is greatly in its favor.

Each year this little work is kept up to date by the rewriting of some sections and the addition of much new matter.

For 1914 the section on Steam Turbines has been rewritten; new sections added are those on Milling and Gear-cutting on the Milling Machine and on Grinding, while among other things tables of American Screw Threads have been inserted. The publishers invite suggestions, hints and corrections.

The "Mechanical World" Electrical Pocket Book for 1914.—By the same publishers. Price 25 cents.

This is a publication on exactly similar lines at the same price as the "Mechanical World" Pocket Diary. Like its older companion, it is revised and brought up to date each year, the new features in the present issue including sections on Telephones, the Electrical Equipment of Ships, Lifting Magnets, Dry Batteries, etc.

Practical Pattern Making.—Second edition.—By F. W. Barrows. Published by Norman W. Henley Publishing Company, 132 Nassau Street, New York. 331 pages; 5 tables; 160 illustrations; 5 x 7 in.; cloth. Price, $2.00.

That practical knowledge and sound common sense are possessed by the author of this book is evident all the way through. The style, for it has a style of its own, is chatty without being vapid, and a great deal of useful information is imparted without our being aware of it.

Youths learning their trade could peruse the book with much profit, especially if they would take to heart the little bits of worldly wisdom which are peppered over the pages here and there, as well as merely the items which deal with the avowed subject-matter of the book; older heads will not be likely, of course, to gain so much, but as there are generally more ways of killing a pig than by hanging it, even they may find described some other, and perhaps better, method of doing a certain piece of work than their own. Information is given on Materials and Tools used in Pattern-making, as well as how best to utilize and handle them.

Examples, many of them clearly illustrated, of various kinds of wood and metal patterns, together with gating, plate work and plaster work, are given. The book closes with a section on the cost, marking and recording of patterns; depreciation tables showing the value in any given year, with a certain assumed life, are here included.

The author is not without a sense of humor, which crops up every now and then, as, for instance, where he tells us that when there are only two boards to choose from it is sometimes a difficult matter to decide which to use, for, "sometimes, it must be confessed, it seems as though each one of the two was a little worse than the other."

Electro Thermal Methods of Iron and Steel Production.—By J. B. C. Kershaw, F.I.C. Published by Constable and Company, London. 233 pages; 100 illustrations; 50 tables; 6 x 9 in.; cloth. Price, $2.25.

Reviewed by T. R. Loudon, of James, Loudon and Hertzberg.

In the preface of this book it is pointed out that there has been a long-felt desire for a practical work on electric furnace iron and steel production. The point of this statement, of course, lies in the exact definition of the word "practical." It is well recognized by iron and steel men that, unfortunately, a great deal of the published material relating to electric furnaces is hardly unbiased, and that the results given are not what one might call practical from a commercial standpoint. It was evidently the author's intention to publish merely the data that was authentic and of a practical nature. The author states that he is not connected in any way with any of the patentees of the furnaces described.

The first chapter is purely introductory. Chapter II. is devoted to general principles and methods. The principles as outlined are well stated, but are necessarily fragmentary owing to limited space. It is emphatically pointed out that the function of the electric current is purely to give heat.

This, of course, is well understood by those experienced in metallurgical work, but, unfortunately, is not always sufficiently emphasized, with the result that in many cases a misapprehension often arises as to the effect of the electric current on the resultant metal itself.

Chapter III. deals with smelting furnaces. A description of the early attempts at smelting is given, together with the reported cost data of the various experiments. This is followed by descriptions of the Grönwall furnaces in Sweden and the smelting operations at Shosta, California. These descriptions and results are mostly taken from published articles which are very familiar to anyone interested in this question. There are also descriptions of the Frick and Chaplet furnaces. The Heroult steel refining furnace is described in Chapter IV., various installations which are well known being discussed. In the same way, Chapters V. and VI. deal with the Girod and Stassano furnaces, respectively. It is unfortunate that the Kjellin and Röechling-Rodenhauser furnaces have been described in the same chapter. As is well known, the latter furnace is not a true induction furnace, while the Kjellin is a perfect example of the much-debated induction furnace.

In Chapters VIII. to X. various furnaces, such as the Keller, and a number of furnaces not very well known, are described. The author describes the Colby furnace among this latter group, using, by the way, the same old familiar cut as an illustration. This furnace might better have been placed with the Kjellin.

Power consumption and running costs are discussed in Chapter XI.

The book is well published, the paper being high grade and the illustrations clear. The material is very largely taken from well-known descriptions in the various technical journals. The book is a good catalogue of these articles.

Mechanical Laboratory Methods of Testing Machines and Instruments.—By Professor Julian C. Smallwood, Syracuse University, N.Y. Published by D. Van Nostrand Company, New York, N.Y. 333 pages; illustrated; 5 x 7½ in.; cloth. Price, $2.50 net.

The author of this book has produced a brief treatise on the mechanical laboratory methods of testing apparatus and machines, and he has entered a field in which there appears to be ample room for a well-written book. So far, outside of a few comparatively large books, there are very few concise and handy works. There is still room for a good book specially written for the use of practising engineers.

The present book has been very nicely gotten up, and is printed in good type. It is divided into three main parts, dealing, respectively, with the calibration of instruments, the analysis of fuels and the products of combustion and the testing of power plant units, with an appendix discussing the reports of tests and methods of conducting students' tests.

In the part dealing with the calibration of instruments, and which occupies over 130 pages, almost every possible measuring device used in mechanical engineering has been taken up. The instruments include scales, gauges, brakes, dynamometers, indicators, planimeters, meters, nozzles, etc., calorimeters and oil and belt testers. To explain the method of treatment the Pilot tube may be taken as an example. In dealing wih this there is, first, a brief discussion of the principles on which it works, then the method of finding by its aid the mean velocity and the location of the point of mean velocity in the pipe. Each instrument is dealt with similarly.

The section on combustion is brief, but deals fairly fully with questions relating to the action of fuels and the calculations relating to their use.

In the last part, on the testing of power plant units, each type of unit is taken separately, and the standard methods of testing and analyzing the results are fully described. Taking the steam engine as an illustration, the matters dealt with are: clearance, valve-setting efficiency and economy, and the machines examined in this way include also steam pumps, boilers, gas engines, air-compressors, fans, water and steam turbines, centrifugal pumps, etc.

The book will prove of help to all engineering students, and the information contained is of such a nature as to be suggestive to engineers who do a reasonable amount of testing.

The Mechanical Engineers' Reference Book.—By Henry Harison Suplee, B.Sc., M.E. Fourth edition, revised and enlarged. Published by Charles Griffin and Company, Limited, London, and by J. B. Lippincott Company, Philadelphia, Pa. 1914. Price, $5.00.

This book differs, in some ways, from ordinary engineering hand-books. It is practically a book of tables, formulas and methods, for engineers, students and draughtsmen. It is intended to be the legitimate successor of Nystrom's Mechanics, which was, in its day, a most useful and handy compendium of information on all subjects connected with engineering. Suplee's work is of convenient size, and has a table of contents and a detailed index. The first page of each of the principal sections, fifteen in all, are "thumb-cut," so as to be easily found and opened without special reference to the index.

In dealing with mathematics—the first of the larger sections—short cuts are given, and handy "kinks" for quickly getting results, without a repetition of "what we may" call "common knowledge." In handling the subject of mechanics, the consideration of the theory of the science is taken up and developed so that it leads to the statics of framed structures, and thus deals with roofs of buildings and with bridges. Dynamics is included in this section, and explanations of all the units, such as that of force, work, power, momentum, etc., etc., are given.

In the section known as Mechinical Engineering, a mass of constantly used matter has been compressed into small space. There is, first, the materials of engineering, tables of weights of pipes, bars, bolts, etc., specific gravity of various substances, facts about pipes, couplings, bolts, nuts, wire rope, followed by the hundred-and-one things which crop up in the engineer's daily life. The strength of materials deals with matters concerning tension, compression, bending, shearing, torsion, and the elements of structural material. Machine design takes up a most important subject to the mechanical engineer. Formulas are given and methods indicated by which the strength of so simple a tool as a wrench may be calculated and properly designed. Keys, key-ways, journals, shafts, bearings, teeth of wheels, belts, rope-drives, and many kindred topics are treated in this practical and easily understood way.

The sections on heat, air, and water give facts which are necessary to be known. Fuel contains many useful tables of the calorific value of combustibles, solid and liquid. Steam follows, with useful tables and information of a thoroughly practical kind. There is a section devoted to steam boilers, and in it tables of various kinds are set down, and information is placed before the reader concerning evaporative power, cost of gaining evaporative efficiency, chimneys and their function and effects. An important feature is the code of rules for conducting boiler tests, together with the results of numerous trials. This section is followed by one on steam engineering, in which horse-power is fully explained and its use made plain. Methods of testing steam engines are detailed and valve cut-off, proportions of cylinders for compound engines. The rules, or code, for steam engine testing are quoted in full,

and the interpretation of indicator cards, and heat analysis, has a place in this section. Steam pipe diameters and port areas are gone into in their various sizes and relationships. Main valves, link motions and condensers are also dealt with. Among locomotive data, formulas for resistances are given, including speed on grades and curves. The tractive power of locomotive and the powering of steamships are discussed. The steam turbine, with "trial figures," are given; also internal combustion motors, the gas engine diagram and rules for conducting gas and oil engine tests.

Under the head of electric power there are tables of various kinds, and some neat and very clear explanations of the equivalents and expressions of electric and mechanical data, and the many analogies between the flow of water and the "flow" of electricity. The National Electric Code, wiring formulas, electric standardization, electric driving, with data sheet on motor power and standard machine tools, are duly set down, together with remarks on electric cranes and motor tests.

The last section is devoted to cost of power. This gives data concerning water plant, costs of water power, steam power as shown by a series of exhaustive tests made with fuel burned directly under the boiler, and with the use of producer gas and with blast furnace heat. Cost of gas power and cost of electric power are indirectly compared. An appendix of forty pages is added in the latest edition of this book, here reviewed. It contains a variety of useful information on many engineering topics. This has been included in the index, and is thus part and parcel of the book. Altogether, the Mechanical Engineer's Reference Book is most fully, what it purports to be, a ready, useful and comprehensive collection of all kinds of data required, and most likely to be used, by a mechanical engineer in the practice of his profession.

The Theory of Heat Engines.—By Wm. Inchley, B.Sc., A.M.I.M.E., University College, Nottingham, Eng. Published by Longmans, Green and Company, London and New York; Canadian Selling Agents, Renouf Publishing Company, Montreal. 492 pages; 246 illustrations; size, 6 x 9 in. Price, $5.00.

This book is largely a treatise on the Thermodynamics of Heat Engines, although it also gives a few chapters on mechanics, in which it deals with balancing, governing, etc. Following the usual practice of most books along the same line, the author first gives the properties of the various working fluids, viz., gases, steam and other vapors, and then takes up the application of these fluids to the various engines, e.g., the steam engine, steam turbine, air-compressor, refrigerating machine, gas engine, etc. The work then takes up the practical testing of these machines and gives examples.

The first forty pages are devoted to the gases, and their application is given to air engines more for the sake of illustration, presumably, than for any practical value the latter engines have. Then follow 113 pages on steam and reciprocating steam engines, this whole important matter being fully dealt with in detail and various points illustrated by numerical examples. In this discussion, as well as elsewhere in the book, the author has freely used higher mathematics, and, indeed, it is difficult to see how one can develop any valuable solution of the heat engine problem without a working knowledge of the calculus.

Chapters dealing with refrigeration, the flow of steam in nozzles, etc., the theory of the steam turbine, of air-compressors and motors contain much useful and well-arranged material. The theory of gas and oil engines is fully treated, and a chapter is specially devoted to the variable specific heat theory. Some attempt has also been made to explain the methods of testing engines and boilers.

The last 100 pages, dealing with the mechanics of the engine, almost seem out of place, considering the general nature of the rest of the book, although objection cannot be made to them, because the information given is of value and belongs to the theory of heat engines. These chapters deal with valve gears, twisting moment diagrams, balancing and governors, and in parts of this, more especially the moment diagrams, the author has treated a subject analytically which essentially belongs to the province of the drafting board.

While the diagrams in the book are well drawn, probably some improvement would have resulted from a number of illustrations of actual machines. The general treatment is, however, excellent, but can only be read by men of good technical training.

PUBLICATIONS RECEIVED.

Winnipeg Electric Railway Company.—Annual report for the year ending December 31st, 1913, showing gross earnings of $4,078,694.75.

5,000 Facts About Canada.—1914 edition.—Compiled by Mr. Frank Yeigh and published by the Canadian Facts Publishing Company, Toronto.

Shawinigan Water and Power Company.—Annual report for 1913 showing gross revenue of $1,690,882.81, outlining extensions for plant, water conservation, development of Cedar Rapids, etc.

The Mineral Production of Canada, 1913.—A preliminary report, prepared by John McLeish, B.A., chief of the division of mineral resources and statistics, Mines Branch, Department of Mines, Ottawa.

Mineral Production of British Columbia, 1913.—Bulletin No. 1, 1914, of the British Columbia Bureau of Mines, a preliminary view and estimate compiled by Wm. Fleet Robertson, Provincial Mineralogist.

Brandon.—A 72 page booklet, descriptive of the city of Brandon, Man., outlining its possibilities as the railway and distributing centre, and containing many photographs of streets, buildings, industrial plants, etc.

Levels of Lake of the Woods.—Progress Report of the National Joint Commission on the question between Canada and the United States of the Levels of Lake of the Woods and its tributary waters and their future regulation and control.

Department of Public Works, Province of Ontario.—Annual report for the year ending October 31st, 1912, of the works under the control of the Public Works Department, comprising the reports of the deputy minister, architect engineer, superintendent, accountant, etc.

Fuel-Briquetting Investigations.—Bulletin No. 58, United States Bureau of Mines, outlining fuel-briquetting investigations since 1904; commercial aspects of the process; necessary equipment; costs; characteristics of briquets; tests; details of experiments, etc. 278 pages; illustrated.

Mineral Production of Canada during 1912.—Annual report of the Mines Branch, Department of Mines, compiled by John McLeish, B.A. The report covers metallic ores, non-metallic products, structural materials and clay products, besides a general summary of the mineral production and explanatory notes.

Effect of Smoke on Building Materials.—Bulletin No. 6, of the smoke investigation carried out by the Mellon Institute of Industrial Research and School of Specific Industries, University of Pittsburg. It contains chapters on the chemistry of soot and the corrosive products of combustion; the effect of smoke on exterior and interior paint coatings, stone, metals, etc.

Currents in the Gulf of St. Lawrence.—By W. Bell Dawson, Superintendent Tidal and Current Survey, Department of Naval Service, Ottawa. The report gives a descrip-

tion of the currents on the surface as a mariner may expect to find them in any locality; and an account of the general circulation of water in the gulf, together with the characteristics of its waters in regard to temperature, density, etc.

Report of the Minister of Lands, British Columbia.—The annual report for 1913 of the Minister of Lands of British Columbia contains the report of office statistics, of the Superintendent, of the pre-emption branch; of dry farming experimental work, and various other reports from government agents. The volume is well illustrated by maps and photographs, and comprises over 500 pages.

Investigations at James Bay during 1912.—Report to the Temiskaming and Northern Ontario Railway Commission by J. G. McMillan, supplemented by investigations during 1913. The report covers ice conditions and a character of channels in the Estuary of the Moose Jaw river; Reconnaissance of the south coast of James Bay; Navigation and Reconnaissance of the south coast of James Bay; Tides and Currents. The report also contains an account of Reconnaissance for the extension of the T. and N.O. Railway to James Bay by W. R. Maher.

The Mortar-making Qualities of Illinois Sands.—Bulletin No. 70, by C. C. Wiley, Department of Civil Engineering, University of Illinois, Urbana, Ill. Issued by the Engineering Instrument Station of that University. The bulletin discusses the effect of the characteristics of sand upon the quality of mortar. The results of a series of tests on thirty-two representative Illinois sands are given in tabular form and discussed. The classification of different sands is also proposed and specifications for each class are suggested.

Industrial Training and Technical Education.—Report of the Royal Commission. Part 1 forms the report of the Commission's opinions and recommendations. Part 2 covers such phrases of the study as elementary, secondary and higher education in relation to industrial training and technical education, manual training, household science, vocational education; industrial training and technical education in relation to national problems, needs, duties and rights of citizens, etc.; industrial research; education for rural communities. Part 3 contains the report of the Commission on inquiry in various countries, while Part 4 is devoted to details of the inquiry in the various Provinces of Canada.

CATALOGUES RECEIVED.

Small Direct Current Generators.—Bulletin A-4188, Canadian General Electric Company, Toronto, descriptive of type C. V. C. belted generator.

Steam Power Plants.—A 42-page illustrated catalogue describing some steam power plant installations. Issued by Lockwood, Greene and Company, Boston.

Small Motor Generator Sets.—Bulletin No. A-4190, descriptive of types M I C and M C C, Canadian General Electric Company, Toronto.

Chain Belt Power.—A handsomely illustrated 16-page catalogue descriptive of powers and equipment manufactured by the Chain Belt Company, Milwaukee, Wis.

Excavators.—A handsomely illustrated 16-page catalogue descriptive of the P. and H. Excavator. Issued by Pawling and Harnischfeger Company, Milwaukee, Wis.

Westinghouse Electric Fans.—Circular No. 165 of the Canadian Westinghouse Company, Limited, Hamilton, descriptive of the various types of fans offered for 1914.

Single-Phase Induction Motors.—Bulletin A-4185. Issued by the Canadian General Electric Company, being a general description of type K S motors and the field for their use.

Chicago Coal Drills.—Bulletin No. 150 of the Chicago Pneumatic Tool Company, illustrating and describing the Chicago Coal Drill for compressed air, electrical or hand-operation.

Electric Fans.— large 42-page illustrated catalogue of the Canadian General Electric Company containing descriptive information concerning style and rating, etc., of fans for various uses.

Mesta Improved Pickling Machines.—An 8-page illustrated catalogue descriptive of machine adapted for pickling metal objects of any shape. Issued by the Mesta Machine Company, Pittsburg.

Deferential Pump-Governor.—Ronald Trist and Company, Limited, London, E.C., have issued a cleverly gotten up catalogue on the "Thermo Feed" deferential pump-governor, its uses and working details.

Phenix Sight-Flow Indicator.—Bulletin No. 57 of the Richardson-Phenix Company, of Milwaukee, Wis., descriptive of device which may be inserted in water lines to indicate electrically any interruption of flow.

Wiring Devices.—Electrical supply catalogue of Factory Products, Limited, Toronto. 112 pages of details and prizes, of sockets, receptacles, plugs, fuse-blocks, clusters, outlet boxes, fuses, switches, cut-outs, cabinets, wall-boxes, etc.

Aluminium Low-tension Insulated Cables.—A 14-page pamphlet, issued by the British Aluminium Company, Limited, Toronto office, 60 Front Street West, being a reprint of an article in the Electric Review based on economical considerations.

Aluminium in the Construction of a Chemical Plant.—A 16-page catalogue, issued by the Toronto office of the British Aluminium Company, Limited, outlining economic possibilities offered by aluminium in its application to the plant and accessories of the chemical industry.

Cut-Off Valves.—The Lagonda Automatic Cut-Off Valves are described in the latest catalogue of the Lagonda Manufacturing Company, Springfield, Ohio. The catalogue also briefly describes water strainers, ball-bearing and thrust-bearing turbines for removal of scale, tube cutters and air or steam-driven cleaners.

Modern Methods of Heating, Ventilating, Sanitary and Electrical Design.—A 64 page pamphlet, published by the Canadian Domestic Engineering Company, Limited, Toronto, containing illustrations of installations and data descriptive of the engineering equipment in many recently constructed Canadian buildings.

Cranes.—Catalogue No. 26 of the Northern Engineering Works, Detroit, U.S.A., the Canadian branch of which is the Northern Crane Works, Walkerville, Ont. The catalogue illustrates electric and hand-power travelling cranes, electric and pneumatic hoists, bucket-handling and railway cranes. The catalogue is well illustrated and carefully condensed and occupies 64 pages.

Evershed's Electrical Instruments.—A 40-page catalogue descriptive of indicating and recording ammeters and volt meters, switchboard and portable types; indicate and recording leakage instruments, capacity meters, pyrometers, speed indicators, testing sets, etc., as manufactured by Evershed and Vignoles, Limited, London, E.C., for whom R. H. Nichols, Dineen Building, Toronto, is Canadian selling agent.

Structural Steel and Iron.—The Manitoba Bridge and Iron Works, Limited, have issued a 216-page cloth-bound catalogue descriptive of beams, girders, lintels, trusses, columns, stand-pipes, ornamental iron, highway bridges, steel tanks and towers, contractors' supplies, etc. The catalogue is specially arranged for the practical use of architects, builders, contractors, etc., and contains tables and notes on the application of structural steel and iron in modern building construction.

Coast to Coast

Galt, Ont. The Galt board of works has asked that $25,000 be placed to its credit to be expended in road improvements in 1914.

Toronto, Ont.—It is stated that by May the Timiskaming and Northern Ontario Railway's "Cobalt Special" will be composed of all steel equipment.

Victoria, B.C.—The engineering department of the city of Victoria has cut down its estimate on the local improvement work to be done in 1914 to about $425,000.

Newmarket, Ont.—Plenty of pure water is now being obtained from the 12 artesian wells supplying the town, and the flow amounts on an average to about 180,000 gallons per day.

Montreal, Que.—The Grand Trunk Pacific reports that work on the mountain section is proceeding day and night. There is a gap of some ninety miles to be filled up. This will be accomplished, it is believed, by the end of April.

Victoria, B.C.—The Victoria city council has approved the resolution forwarded to the mayor of Victoria by the mayor of Windsor, Ont., asking for the approval of the movement on foot to memorialize the Federal authorities to approve of the construction of a deep waterway from the Great Lakes to the Atlantic Ocean via the St. Lawrence River.

Calgary, Alta.—The first official train of the G.T.P. Calgary-Tofield branch has been pulled over the line from Mirror, the first divisional point west of Calgary. The road is pronounced to be in splendid running order, and a regular service will be inaugurated between Calgary and Edmonton as soon as spring opens.

Edmonton, Alta.—Last year the electric light department of Edmonton cleared a net profit of [illegible], or an approximate equivalent to 25 per cent. of the capital invested. As a consequence, the city council has a new light and power tariff; and a reduction will be made in light revenue of $32,000, in September change of $15,000, and in power revenue of $23,000.

Saanich, B.C.—The municipal council is taking action to restrain the Warren Construction Company from proceeding with work on the roads of the municipality. It is declared that the contract is invalid because the contemplated expenditure was beyond the municipal revenue for 1913, and that the city could not enter into the contract without a valid by-law for the provision of the money.

Vancouver, B.C.—It has been announced by J. G. Sullivan, chief engineer for the C.P.R., that approximately $20,000,000, exclusive of expenditure on terminals in Vancouver, will be spent in Western Canada in 1914. Of this amount, the larger portion will be required for the improvement work and double tracking proposed in British Columbia. However, new line to the extent of 600 miles is to be laid on the prairies; but the heaviest cost will be for the supply of rails and new ties.

Toronto, Ont.—The annual report for 1913 of the Hydro-Electric Commission was tabled in the Ontario House on March 16. A comparison was made showing the extent of the system at the end of 1913 and at the end of the previous year. The total annual expense for 1913 was given as $1,991,043, while for 1912 it was $1,377,168; the total revenue for 1913, $2,611,918, for 1912, $1,617,674; the net balance, or profits in excess of depreciation, in 1913, $390,395, and in 1912, $60,65[illegible]; and the total plant [illegible], while in 1912 it was [illegible].

Port Moody, B.C.—Preparations are being made by the Imperial Oil Company for the establishment of storage tanks and a refining plant on the north shore of Burrard Inlet, near Port Moody; and construction work will be started at an early date. The C.P.R. is ballasting the spur line from Port Moody, which was built last year, so that the steel and cement for the tanks can be transported to the site. The Imperial Oil Company acquired some time ago a 100-acre tract for its Western British Columbia base, and three large tanks, a number of small reservoirs for storing the different kinds of oil and a big machine plant will be established. A wharf 750 feet long will be built for berthing the ocean-going steamships which will bring the crude oil from California to the company's new works. The big tanks will have a storage capacity of 150,000 barrels. It is expected that the plant will be in operation within three months from the time construction work is started.

Minnedosa, Man.—On March 10, a conference was held at Minnedosa between representatives of the three private power companies on the Little Saskatchewan River, the council of Minnedosa, the superintendent of the Dominion water power branch and the assistant cheif engineer of the Manitoba hydrographic survey, regarding the power situation on the Little Saskatchewan River. It was explained that the Manitoba hydrographic survey had made a complete reconnaissance investigation of the power possibilities on the Little Saskatchewan, and also of the possibilities for the control and conservation of the river in the interests of the present and prospective powers on the river. The general result of these investigations indicated that a comprehensive system of control could possibly be worked out by utilizing the various lakes in the upper waters of the Little Saskatchewan and within the Riding Mountain forest reserve. The Department of the Interior has for some time been considering the best means of working out such a comprehensive control system, but desired to have a full discussion in the matter with the various private interests involved before taking any definite action. After some discussion, a resolution was unanimously passed expressing the approbation of the town of Minnedosa and the three power companies on the river in the work already done by the Manitoba hydrographic survey, and urging that it be supplemented by such further investigations as would be necessary to enable a final definite policy of conservation.

Montreal, Que.—The report of the improvements effected by the Montreal Harbor Commission in 1913 shows the completion of the Harbor Commissioners' railway line to high level from Molson's Creek to Tarte pier; the completion of 2 permanent transit sheds; an advancement almost to completion of the work on the drydock site, providing a large basin for the new floating drydock Duke of Connaught, and a large area of made land for the shipyard; the completion to the length of 2,000 feet of new quay walls of cribwork and concrete, and the partial completion of 2,000 additional feet; the construction of 4 miles of new railway track as well as the improvement and relaying of one mile; and the advancement of the removal of the artificial works at Moffatt's Island. Further, construction of a large industrial wharf at Pointe-aux-Trembles, and of two new transit sheds on the high level bulkhead wharves sections 24 and 25, was also started; a new electric hoist, with bridges connecting with the upper stories of the sheds on the Alexandra pier was built; new paving was laid on portions of the wharves; a start was made in substituting concrete for the superstructure of some of the old wooden piers in the central portion of the harbor, and additions and improvements were made to the various harbor plants. Elevator No. 2 and its connecting conveyer system to all berths in the central part of the harbor was operated during the whole season; and elevator No. 1 also worked satisfactorily, though an addition of one and a half times its storage capacity was being installed.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page , a directory of such societies and their chief officials.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

A meeting of the Electrical Section of the Canadian Society of Civil Engineers was held in Montreal on March 19th. Mr. Julian C. Smith was the speaker, and his subject was the performance of electrical insulators. It was followed by a good, general discussion, in which many prominent engineers took part.

Ottawa Branch.—A paper on "Structural Steel Design from a Commercial Standpoint" was read on March 19th before a good attendance of the members of the Ottawa Branch, by Mr. E. S. Mattice, of the Dominion Bridge Company, Montreal, and Mr. W. F. Gronau, of the Structural Engineering Company, Montreal. Mr. Mattice dealt with the practical side of the subject, and Mr. Gronau dwelt upon the theoretical.

Toronto Branch.—This evening (March 26th) Mr. J. G. G. Kerry, of Kerry and Chace, Limited, Toronto, will address the Toronto Branch on "The Proposed Terminal of the T. and N.O. Railway System on James Bay."

Victoria Branch.—On March 12th a paper on "Modern Guns" was read to the members by Captain N. C. Sherman, of the Pacific Coast Ordnance Department, and created a great deal of interest.

At the next meeting of this Branch Mr. H. W. E. Canavan will give an illustrated paper on "Modern Irrigation in British Columbia." This meeting is scheduled for April 9th.

ANNUAL MEETING OF S.L.S. ASSOCIATION.

The Saskatchewan Land Surveyors held their annual meeting at Regina a few weeks ago. The following officers were elected for the ensuing year: President, A. C. Garner, D.L.S., S.L.S.; vice-president, W. A. Begg, D.L.S., S.L.S.; secretary-treasurer, H. G. Phillips, S.L.S.. Counsellors—Messrs. W. R. Reilley, D. Alpine Smith, W. M. Stewart, Saskatoon, and J. A. Morrier, Prince Albert. Auditors—Messrs. E. C. Brown, G.T.P., and O. F. Cummins, Regina.

A number of interesting addresses were given during the course of the convention. The general discussion emphasized the need for raising the standard of the work of the profession, and considerable time was devoted to an investigation of the ways and means of best accomplishing this end.

Last year the association obtained legislation giving them complete control of the examinations and discipline of the members. In securing this advanced legislation the members felt that they had made great strides in raising the standard of the association, but it was felt that even better discipline could be obtained and more efficient work accomplished.

Mr. A. T. Thompson, S.L.S., of Grenfell, contributed to the programme by reading a paper on his "Reminiscences of the Early Days in the North-West," with notes on the Indian Tribes, which described his own personal experiences in this country during the last 30 years, and which was well received. Mr. Thompson was asked if he would contribute to the biography of the members, and he consented to do so.

On Monday the president, Mr. A. C. Garner, D.L.S., S.L.S., spoke of the most important matters to be considered, and gave a general outline of the work of the association. The secretary then presented his report and financial statement, showing that the membership has materially increased since the last annual meeting, and that all the members were taking an active interest in the work of the organization.

A very interesting paper was read by Mr. R. H. Montgomery, S.L.S., of the firm of Morrier and Montgomery, of Prince Albert, on "Practical Astronomy," dealing particularly with "Equation of Time." The paper was well conceived, and dealt with some very technical matters.

Mr. Stewart, S.L.S., of the firm of Phillips, Stewart and Lee, of Saskatoon, read a paper on the "Design and Construction of Open Ditches," pointing out particularly the drainage work done in this province and the machinery most suitable or this particular kind of work, taking into consideration the conditions of the soil and the size of the ditches required to be constructed. After giving his paper he was asked to furnish particulars as to this kind of machinery. He promised to obtain information regarding a plan which he believed would in time lessen the cost of construction of ditches. It was pointed out that difficulties which heretofore prevented a great deal of drainage work in this province were being removed, and that in the very near future an enormous amount of drainage work would be accomplished.

It was decided to have these papers printed and distributed for the use of the members of the association; also a statement of the association generally covering the four years that it has been in existence, including all other papers that have been read by members on former occasions.

THE PANAMA CANAL.

Over 100 graduates of the Faculty of Applied Science and Engineering of the University of Toronto were present at a meeting of the Engineering Alumni Association on March 23rd, when David A. Molitor, C.E., gave an illustrated lecture on the Panama Canal. Mr. Molitor, previously professor of Civil Engineering at Cornell University, was designing engineer on locks and dams in the Canal engineering organization. He is thoroughly conversant with the history of the present and earlier projects, as well as with the engineering features of both design and construction. His lecture was accompanied by the exhibition of about 100 lantern views, showing details of concrete and steel construction of the Gatun Dam and spillway, the locks at Gatun, Pedro Miguel and Miraflores, the methods of excavation at Culebra Cut, etc. A description of the construction and operation of the emergency dams which have recently been installed, and which Mr. Molitor designed, created considerable interest.

At the conclusion of the address the members took advantage of a good opportunity to ask questions and an extra half hour was spent in discussion.

In the absence of Mr. E. W. Oliver, the chairman of the Association, the chair was occupied by Mr. T. H. Hogg.

About the middle of April the Association will hold another meeting, which will be addressed by J. L. Weller, C.E., of St. Catharines, on the design and construction of the New Welland Ship Canal, of which project he is chief engineer.

EDMONTON ENGINEERING SOCIETY.

The Edmonton Engineering Society, of which Mr. A. W. Haddow is Secretary-Treasurer, hold meetings, at which papers are read and discussed, on the second and fourth Thursdays of the month.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Deven, 47 Slate Street, Troy, N.Y.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

AMERICAN SOCIETY FOR TESTING MATERIALS —Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

AMERICAN PEAT SOCIETY.—Eighth Annual Meeting will be held in Duluth, Minn., on August 20, 21 and 22, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9-13, 1914. J. E. Pennybacker, Secretary, Colorado Building, Washington, D.C.

PERSONALS.

VERNON C. LUCKNOW, consulting engineer, Victoria, B.C., is in Toronto this week in connection with the construction of the new Hudson Bay store building in the former city.

CHAS. CAMSELL, of the Geological Surveys Branch, Ottawa, recently addressed the Ottawa Field Naturalists' Club on the magnitude and navigability water-powers of the Mackenzie River.

FRED M. OSBORN, of Samuel Osborn and Co., Limited, Clyde Steel Works, Sheffield, England, has just completed a trip through Eastern Canada as the guest of A. E. Myles, manager of Heap and Partners, who are the Canadian representatives of Samuel Osborn and Company.

H. D. JOHNSON has joined the engineering staff of the Eugene F. Phillips Electrical Works, Limited, Montreal, as assistant contracting manager. Mr. Johnson, who is an authority on underground distribution systems, was previously with the Canadian British Insulated Company, Limited.

NELSON P. LEWIS, Chief Engineer, Board of Estimate and Apportionment, New York City, on March 9th delivered an illustrated lecture on "The Administration of Municipal Public Works" before the Graduate Students in Highway Engineering at Columbia University.

ERNEST BELANGER, of the firm of Marion and Marion, Montreal, has received an appointment from the Government of the French Republic. Mr. Belanger was a graduate of L'Ecole Polytechnic and a member of the Canadian Society of Civil Engineers, and of the Engineers' Club of Montreal. In his new position he will hold the title, "Officer of Public Instruction."

L. C. FRITCH, chief engineer of the Chicago Great-Western Railway, has been appointed assistant to the president of the Canadian Northern Railway. Mr. Fritch is a graduate of the University of Cincinnati, and entered railway service in 1884 on the Ohio and Mississippi Railway, of which he was later chief engineer. He was also with the Cincinnati and Deptford Railway as engineer in charge of construction, and division engineer of the Baltimore and Ohio South-Western. Later, he became assistant to the president of the Illinois Central.

Mr. Fritch will assume duties on April 1st. His head quarters will be in Toronto.

OBITUARY.

The death occurred last week of E. B. Temple, of Toronto, in his 77th year. Mr. Temple's career was largely devoted to engineering, and his work is well known to men of the profession throughout the Dominion. He took an active part in the construction of the Grand Trunk Railway between Montreal and Quebec, and upon its completion he joined the staff of the Canadian Pacific Railway at Toronto. A few years later he was placed in charge, by the Government, of harbor development and general waterfront construction work at Toronto, and it was under his direction that the walls and cribwork at the Eastern Gap were built.

Previous to his retirement from active work a year ago Mr. Temple was for 9 years harbor master at Port Arthur.

He was a member of the Canadian Society of Civil Engineers and of the Institution of Civil Engineers of Great Britain.

GEO. H. STREVEL, for many years a prominent Canadian railway contractor, died last week at Portage la Prairie at the age of 79 years.

BACK COPIES WANTED.

Copies of *The Canadian Engineer* for July 21st, 1910; November 3rd, 1910, and November 17th, 1910, are needed by a subscriber in order to complete a volume. Any reader who has one or more of these copies, and who will dispose of them, will confer a favor by communicating with the Editor.

ECONOMY IN HIGHWAY CONSTRUCTION.

Some interesting figures on the economical way of building highways are furnished by a prominent contractor, operating a system of portable railway in the highway construction work at Lockport, New York. They have about four miles of portable track, 40 cars, 36 x 24, and two 5-ton dinky locomotives. Most of this equipment is that of the Orenstein-Arthur Koppel Company of Pittsburg, Pa. The cars are hauled in trains of 12 cars each by one 5-ton dinky locomotive with an arrangement such that there is always one train of loaded cars on the way, one train of empties returning and one train of cars being loaded at the crusher.

The cost of operation is as follows:—

2 drivers' wages per day each $2.75	$ 5.50
2 brakemen (one for each train in transit) $1.75	3.50
Fuel and lubricating oil for two locomotives, and oil for all cars per day	8.00
2 brakemen for maintenance of track, one a foreman at $3 per day, and one at $1.75 per day, total	4.75
The above shows a total outlay for operation including a maintenance of track	$21.75

The amount of crushed stone carried in these cars is problematical, but the amount of stone actually in place spread and rolled and furnished with the equipment is 80 cu. yd. per day. The haul is three miles from quarry to road and, at the cost of $21.75 per day, equals 27 cents per cu. yd. for 3-mile haul—or 9 cents per cu. yd. mile.

The cost of laying portable track and grading up the shoulder of the road for this work will average between 2 and 3 cents per foot, this amount depending largely on the conditions of the road. If the road is of a clay substance, the cost will closely approximate the larger amount, but if the road is of a dry and sandy soil, the cost of laying the track, including grading, is not likely to exceed 2 cents per foot.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21474—March 10—Authorizing Cedars Rapids Manufacturing and Power Company to take additional 25 feet for right of way for transmission line, making in all a width of 125 feet, in parishes of St. Polycarpe and St. Ignace du Coteau du Lac.

21475—March 12—Directing that yard limit at Algonquin Park Station, Ont., be discontinued within 60 days from date of this Order. That if G.T.R. desire to discontinue use of locomotive whistle at station, it shall, within 20 days from date of this Order, file plans for approval of Board, showing a signal system to be established at Algonquin Park Station, and instructions as to operating same; such signal system to be operated either electrically or manually.

21476—March 11—Authorizing G.T.R. to use and operate bridge over viaduct, near Port Hope Station, Ontario.

21477—March 13—Authorizing C.P.R. to construct Lacombe-Easterly Branch of Calgary and Edmonton Ry. across highway on East Boundary of S.E. ¼ of Sec. 24-33-28, W. 3 M., Sask., at mileage 188.26.

21478—March 12—Authorizing G.T.R. to construct siding into the premises of Canadian Clarendon Marble Co., Limited, on Lot 879-80, town of St. Johns, Que.

21479—March 13—Authorizing, subject to terms of consent of Chas. Young, C.P.R. to construct spur for Canadian General Electric Co., Limited, on Subdivision, Lots 21, 22, 23, 24, 25 and 26, Block 69, city of Calgary Alta.

21480—March 13—Authorizing C.L.O. and W. Ry. (C.P.R.) to construct a business spur from a point on its main line at mileage 0 to a point in Lot No. 1 on N.W. corner of Ontario and Dundas Streets at mileage 1.11 (spur mileage), town of Trenton, Ont.

21481—March 13—Authorizing C.L.O. and W. Ry. to construct, by means of grade crossings, its business spur across C.N.O.R. main line and spur at mileages 0.47 and 0.74, town of Trenton, Ont., subject to and upon certain conditions.

21482—March 12—Approving diversion as constructed by C.L.O. and W. Ry. (C.P.R.) at mileage 91.18 from Glen Tay; and rescinding Order No. 18282, dated December 11, 1912.

21483—March 13—Approving location G.T.P. Branch Lines Co.'s station on Moose Jaw Northwest Branch, at Siding No. 11, in Sec. 26-22-6, W. 3 M., Sask., at mileage 63.

21484—March 14—Authorizing G.T.R. to connect its tracks with and to operate its engines, trains, and cars over siding recently constructed by Dominion Iron and Steel Company, at its premises at Point St. Charles, near Wellington Basin, in city of Montreal.

21485—March 13—Postponing cancellation of special mileage rates on grain for milling and export, as published in C.P.R. Supplement No. 3 to C.R.C. No. E-2715 and G.T.R. Co.'s Supplement No. 16 to C.R.C. No. E-2566, and 2, that special mileage rates, as published in Sec. 3 of C.P.R. Tariff C.R.C. No. E-2715, and Sec. 4 of G.T.R. Tariff, C.R.C. No. E-2566 be continued in effect for a period of one year from 20th day of March, 1914. 3. Leave be granted Rly. Cos., to make application to Board at end of such period, for a revision of the rates.

21486—March 13—Directing that G.T.R. install, within 90 days from date of this Order, improved automatic bell at crossing of highway immediately west of Lorne Park Station, Ont., thereafter maintain bell at own expense: 20 per cent. of cost of installing bell be paid out of Rly. Grade Crossing Fund, remainder by Railway Co.

21487—March 13—Authorizing C.P.R. to construct spur for Adolph Lumber Co. at Baynes Lake, B.C., from a point on Baynes Lake [illegible] E.K.D. B.C. Ry. Co., [illegible] spur [illegible] feet from crossing of Great Northern Ry. and connect it with [illegible]. Spur to be constructed within six months from date of this Order.

21488—March 16—Authorizing C.P.R. to construct road diversion under and across main line, Alta. Div. Aldersyde Sub- Div. in Sec. 5-14-23, W. 4 M., at Carmangay, Alberta.

21489—March 14—Authorizing C.P.R. to use and operate two bridges, namely, No. 62.8, Ont. Div., Windsor Sub. Div., and No. 79.1, Ont. Div., Windsor Sub. Div., Province of Ontario.

21490—March 14—Authorizing G.T.R. to operate over four bridges, No. 144 Trout Creek, St. Marys, Mileage 0.60; No. 90 Cull Drain, Blackwell, Mileage 161.40; No. 40, Stream, Tavistock,, Mileage 106.24, and No. 39, Stream, Tavistock, Mileage 104.01, all in Middle Div. 15th Dist., Ont.

21491—March 16—Approving plans showing location and details of freight shed and platform proposed to be constructed by G.T.R. at Prairie Siding, Ontario.

21492—March 16—Amending Order No. 20940, dated Dec. 3, 1913, by striking out figure "5" wherever it occurs in said Order and inserting therefor figures "25," so as to make same read, "Section 12, Tp. 25, Rge. 3, West of 4th Meridian?"

21493—March 17—Directing that C.P.R., within 60 days from date of this Order, install improved automatic bell at crossing of County Road No. 14, village of Hillsburg, Ont., and thereafter maintain bell at its own expense: 20 per cent. of cost of installing bell be paid out of "The Railway Grade Crossing Fund," remainder by Railway Company.

21494—March 16—Authorizing C.P.R. to construct spur for W. T. Williams and J. W. Davidson, Medicine Hat, Alta.

21495—March 17—Authorizing C.P.R. to construct Bassano Easterly Branch across highway between Secs. 5 and 6, Tp. 23-1, W. 4 M., Alberta, at mileage 112.47 of said Branch.

21496—March 17—Authorizing C.P.R. to construct Bassano Easterly Branch across highway between Secs. 25 and 26-21-6, W. 4 M., Alta., at mileage 83.6 of said Branch.

21497—March 16—Authorizing C.P.R. to construct spur to Newcastle Lumber Mills, at Newcastle, mileage 6.64 on Comox Extension of said Esquimalt and Nanaimo Railway, subject to certain conditions.

21498—March 17—Authorizing C.P.R. to re-construct bridge No. 109.36, on Mountain Subdivision, B.C. Division, B.C.

21499—March 17—Directing that on or before June 1st, 1914, the C.P.R. erect a shelter at Groverton, Ont., for the accommodation of passenger traffic.

21500—March 17—Approving revised location of C.P.R main line, as at present constructed, Thomson Sub. Div., from mileage 24.76, at Savona, to mileage 30, and from mileage 32 to 40.62, at Semlin, B.C.; and authorizing construction of an additional track (double track) on said revision; also authorizing, subject to an inspection by Dept. of Public Works for B.C., construction of said additional track across four (4) highways, from mileage 24.76 to mileage 30 and from mileage 32 to 40.62.

21501—March 16—Authorizing G.T.R. to construct bridge 266, at mileage 48.25, over Credit River, near Inglewood, Ontario.

21502—March 16—Authorizing G.T.R. to construct siding, commencing at a point on Northern Div. on Lot 3, Con. 1, Tp. Macauley, Dist. Muskoka, Ont., thence in southeasterly direction across Lot No. 3, and Lot No. 3 in 13th Con. Tp. Draper, and a public highway, into premises of I. C. McLeod.

21503—March 16—Authorizing G.T.R. to operate trains across bridge 130, over Nith River, at mileage 75.64, 17th Dist. near Princeton, Ontario.

21504—March 17—Authorizing G.T.R. to re-construct nine (9) bridges on 4th District of its railway, in Province of Quebec.

ROYAL BANK BUILDING FOUNDATION WORK

TALLEST BUILDING IN BRITISH EMPIRE UNDER CONSTRUCTION IN TORONTO — GENERAL FOUNDATION SCHEME DESCRIBED—NOTES ON PIERS, COLUMN BASES, GRILLAGES, ETC.

THE steel frame building which is now in the course of erection on the northeast corner of King and Yonge Streets, Toronto, is in every way an extremely interesting undertaking. The structure has been designed upon the most up-to-date and modern lines, as regards both engineering and architectural practice. The intention of this article at the outset was to deal with the engineering features of the entire structure, but owing to its size and the extremely large amount of important matter which a complete description of it would involve, beyond giving a few particulars of a general nature only the foundations will be dealt with in the present article.

Fig. 1.—Showing Stage of Work on January 15th, 1914.

The building, which is to be known as the Royal Bank Building, will be twenty stories in height, which will give it the distinction of being the tallest building in the British Empire. The over-all dimensions will be 81 ft. 2½ in. on King Street, 112 ft. 2⅝ in. on Yonge Street, and approximately 273 ft. from sidewalk to roof. Fig. 8 shows the progress which has been made on the building up to March 20th. The ground plan is practically rectangular, with the exception of a light court which is introduced near the elevator shaft on the eastern side.

The basement is divided into three sections, that on the front, or King Street, being 14 ft. 7 in., the central portion 18 ft. 10 in. and the northern section 23 ft. 10 in. below the level of the sidewalk. The ground floor level over the whole area of the building is 4 ft. below the sidewalk.

Excavation.—The soil on this site is composed of an upper layer of clay extending to a depth of about 30 ft.,

directly beneath which lies a deposit of moderately hard and shaly clay for a depth of from 2 to 3 ft. Upon sinking through this (or to about 33 ft. below sidewalk level)

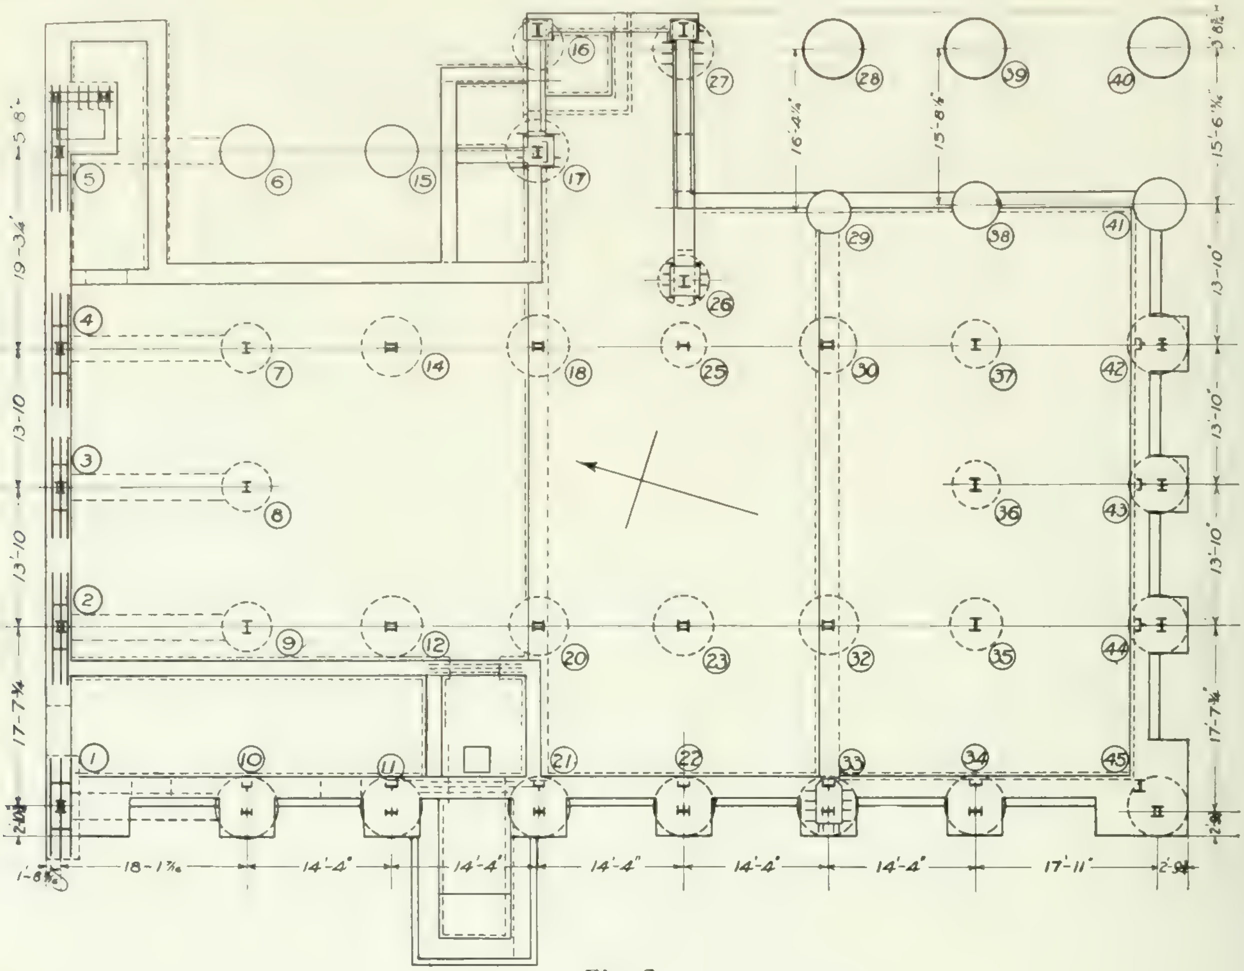

Fig. 2.

a very hard, dense shale is reached which, from borings that have been made in the vicinity, has not been found to change much in character in six hundred feet of depth, according to Professor Parks, of the department of geology, University of Toronto.

A test made on an isolated sample of this shale, in the testing laboratories of the University of Toronto, showed first signs of crushing when a load of 70 tons per square foot had been imposed. It is upon this hard shale of rock that the foundations of the building rest.

Caissons.—As no part of the basement is excavated down to the shale, caissons were sunk through the clay until bed rock was reached at each of the 41 points where a column foundation was required. Each column is carried upon a separate pier, with the exception of those which are carried on cantilever girders, or on plain girders, as shown on Fig. 2. All piers, with the exception of those along the extreme north end of the building, are circular in plan, and vary in diameter from 4 ft. 4 in. to 6 ft. 8 in. at the top, according to the proportion of the load that is transmitted to them.

These piers are increased in diameter at the bottom by an additional 2 feet in each case, the enlargement tapering through a height of 3 feet. On an average, each pier carries a load of about 14 tons per sq. ft. Owing to the nature of the soil, in sinking for piers it was found unnecessary to use any form of hollow caisson or piling as the clay walls were self-sustaining. Consequently these excavations were made exactly of the size and shape required, and on bottom being reached, were filled in with concrete to the requisite height to take the grillages. The concrete used was of a 1:2:4 mix, the stone being about 1½-in. gauge.

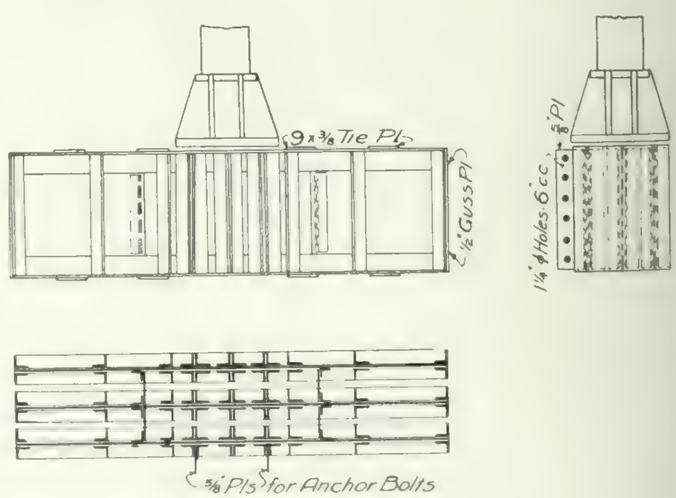

Fig. 3.

Grillages.—The grillages were composed of steel I-beams varying from 10 in. @ 30 lb. to 24 in. @ 100 lb., those for the main columns being composed of two sets of four 15-in. @ 50 lb. I's, and each set of 4 beams being

connected by means of ¾-in. through-bolts with pipe separators between the beams. One set was placed at right angles to, and above the other upon the concrete piers. They were carefully levelled up and the whole then

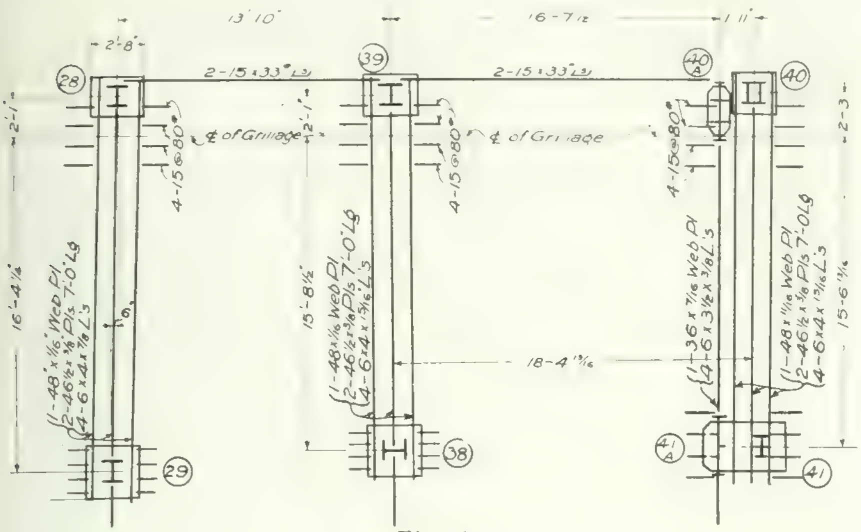

Fig. 4.

grouted in level with the top of the uppermost grillage. Section "A" of Fig. 5 illustrates the arrangement.

Column Bases.—Each of the piers constructed as above are capped with a heavy cast iron column base similar to those shown in Fig. 5. These bases were cast from tough grey iron. The actual test made on coupon bars one inch square in section and 12 in. long, loaded at the centre, gave on an average a breaking load of 30,000 lb. The upper surface of the cast iron bases is planed true and parallel to the lower surface, and holes are drilled for bolts to connect the columns to bases. In Fig. 1 several of these bases may be seen on the ground ready for placing. In designing these bases provision was made for 1 inch of grout between the base and the steel grillages. In setting, small wooden wedges were used under the corners of the castings, by which means the bases were set dead level, and raised or lowered to the exact elevation required. Grouting was then introduced through vertically cored holes at the centre of the casting, and by this means the space between grillage and base was thoroughly filled in. The wedges used in levelling were not removed, and, being of wood, will give under any compression to which they and the grouting may be subjected, thus insuring even distribution of the load over the whole surface without damage to the castings.

Type of Piers.—All piers are circular in plan with the exception of those under Columns 1, 2, 3, 4 and 5, along the north end of the building, and Columns 46 and 47, carrying a smoke stack at the north-east corner of the building. Columns 1 to 5 are each carried by ~~four~~ three plate girders bolted together as one, and running parallel to and under the north wall. (See Figs. 2, 3 and 5.) It should be mentioned that in the City of Toronto all building foundations must be within the limits of the particular building lot; footings cannot be carried out under an adjoining lot. Consequently it is sometimes necessary to cantilever out to place the columns sufficiently close to an adjoining wall. Owing, however, to the depth of the basement at this end of the building, bed rock is not more than 10 and 11 ft. below the column bases, and it was not necessary to use cantilever girders to carry these five columns. Instead, a trench was cut along the extreme northern limit of the lot, extending inwards about three feet, and downwards to bed rock. This trench was filled in with concrete to the requisite height, diagonal tie rods being inserted (as shown in Fig. 5) which later formed part of

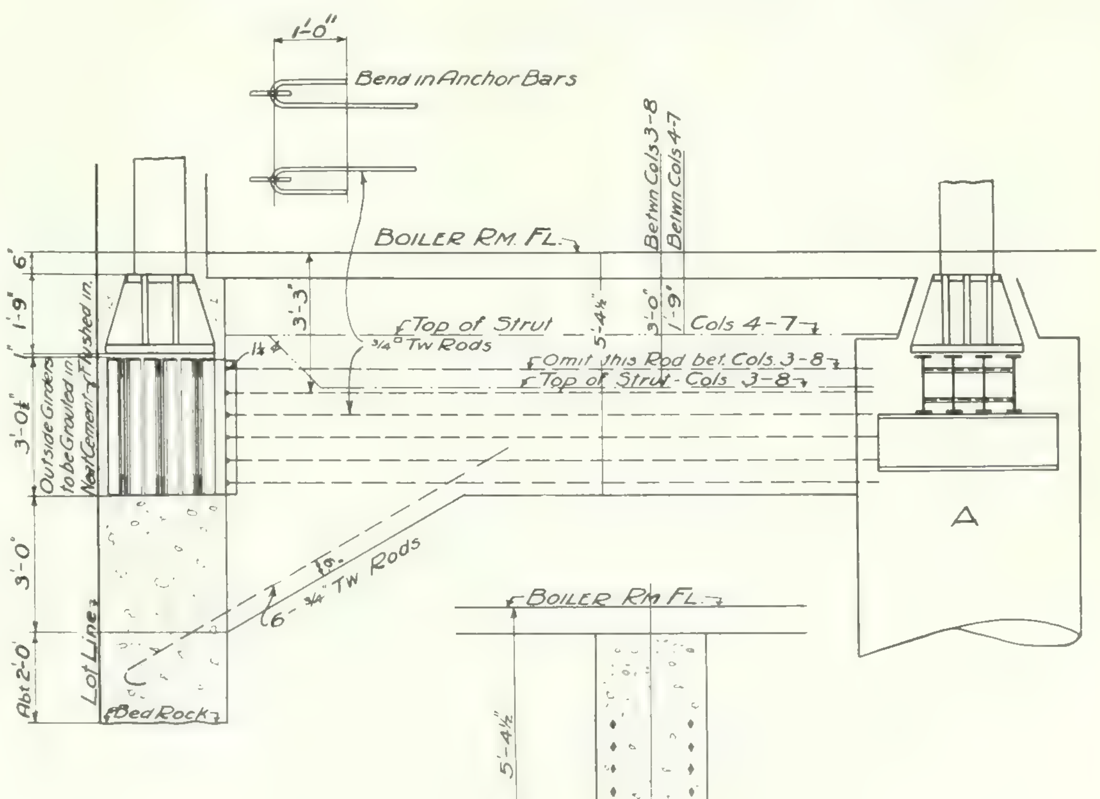

Fig. 5.

the horizontal reinforced concrete struts running at right angles to the girders. On this concrete wall were placed the plate girders already referred to. Twisted steel anchor rods were then hooked into the projecting plates provided on girders, and laid in a trench 2 ft. 6 in. wide

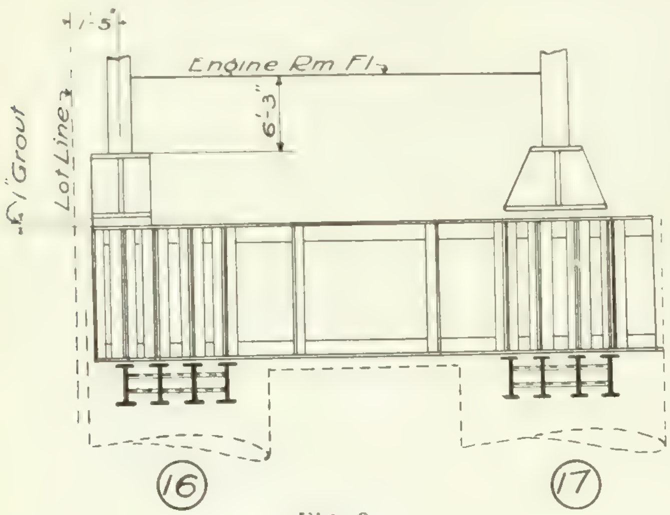

Fig. 6.

by 5 ft. 0 in. deep, extending out at right angles to the girders and butting onto the caissons of the next row of columns. The girders, and trench with rods, were then filled in with concrete, the outer girder being grouted with neat cement flushed in to lot limit, as shown in Fig. 5. The girders are surmounted by cast iron column bases levelled and grouted as previously described.

Columns Nos. 45 and 45a.—The foundations for columns Nos. 45 and 45a present several features which are worthy of special description. These columns are respectively the main and auxiliary columns at the southwest corner of the building.

The main column runs up to the full height of the building, but the auxiliary stops at the third floor level, and carries the wind bracing up to that point. Above the third floor the wind bracing is carried by the main column.

The pier for these columns is circular in plan, as shown in Fig. 9, and is surmounted by a special grillage composed of a bottom course of five and an upper course of six 12-in. @ 40 lb. I-beams, the latter course laid at right angles to the lower, as shown in Fig. 9. It will be noticed that the beams in the upper course are carried diagonally towards the centre of the building, to form a base for the auxiliary column. The weight thus applied would cause an eccentric loading upon the pier, the load centre approaching towards the inner wall of pier. To overcome this

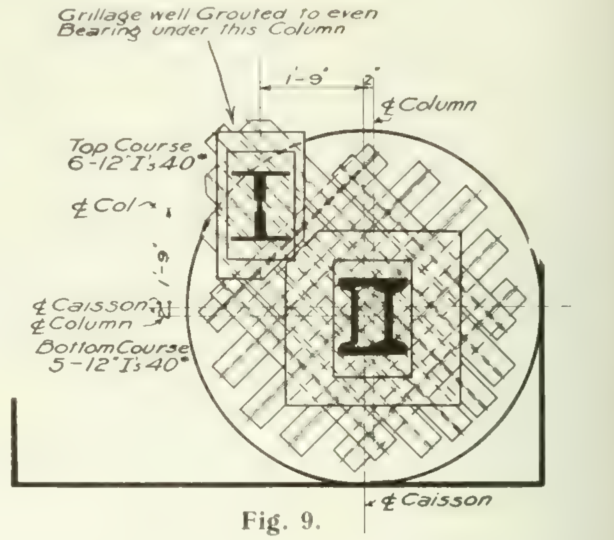

Fig. 9.

eccentricity of loading, the position of the pier has been moved diagonally inwards by 2¾ in., thus concentrating the combined load about the centre of the pier.

Cantilever Girders.—Columns 17, 27, 28, 39 and 40 on the east side of the building abut on an existing structure, and commence from a level considerably above the rock (as very little basement excavation was required under this portion of the building). They are carried upon cantilever girders. These girders are each carried in turn by two circular caissons which are surmounted by single grillages composed of four 15-in. I-beams. This is diagrammatically shown in Figs. 4, 6 and 7.

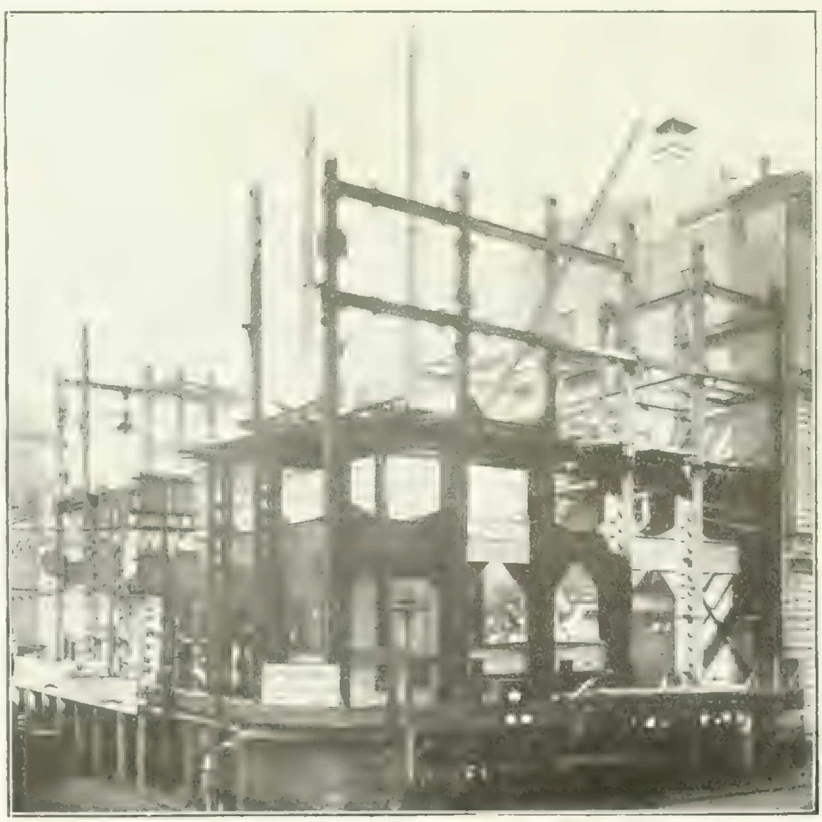

Fig. 8.—State of Erection of Royal Bank Building on March 20th, 1914.

The girders are each built in three longitudinal sections, as shown in Fig. 7, and are bolted together through diaphragms after being set in place. The spaces between the girders are filled with concrete, and they are also encased in the same material. A cast iron column base is set at both ends of each girder and grouted in, as shown in Fig. 6. This cut also shows the method of cantilevering.

The building is being erected for the Guardian Realty Company of Canada, Limited, at a cost of about

$1,250,000, including engineering and architectural fees and the carrying charges during construction. It will be managed and operated by Messrs. J. and L. M. Wood, Toronto, It is being built to the designs of Messrs. Ross and Macdonald, architects, Montreal and Toronto, to whom we are indebted for the photographs and drawings illustrating this description of foundation work. The whole of the steel-work for the building and foundations

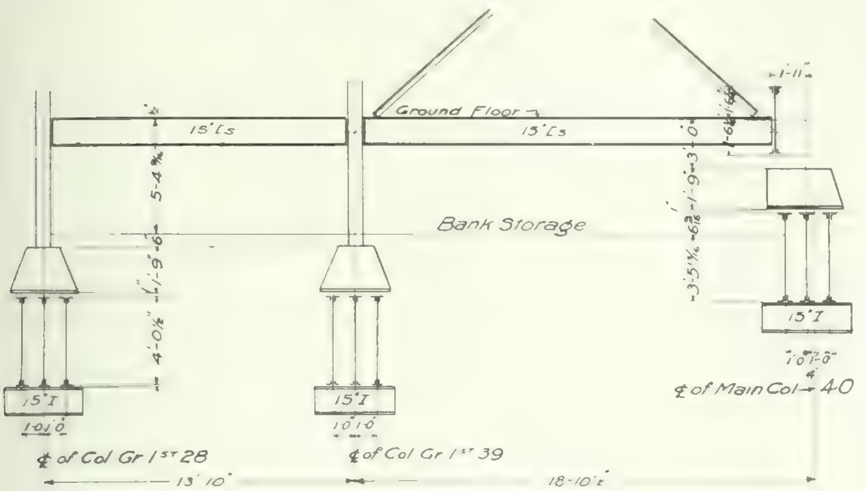

Fig. 7.

was designed by Messrs. Purdy and Henderson, Montreal. The steel is being supplied by the Dominion Bridge Company. Mill, shop and field inspection of all steel and testing of cement are being carried out by the Dominion Engineering and Inspection Company, Montreal and Toronto, to Mr. B. W. Seton of which firm we are indebted for much of the above information. The George A. Fuller Company, Limited, of New York, are the contractors and expect to have the building ready for occupancy in October next.

MOVING AN 8,000-TON BUILDING.

According to a recent article in the London Times an 8,000-ton three-story brick school building has been moved 1,650 ft. by placing it on a raft of timbers, cutting it loose from the supporting steel columns, hauling it across some sandy ground, four streets, and two street car lines, and turning it through an angle of nearly 180 deg.

The building rested on 60 steel columns, the heaviest load on an interior column being 135 tons and on an exterior column 160 tons. In preparing the building for the journey it was shored up on 12-in. by 12-in. timbers running under the floor-beams. The building is 142 ft. wide and 120 ft. deep. The columns are symmetrically spaced about the centre of the 142-ft. side, but are irregular in the other direction, which accounts for the uneven spacing of the 14-in. by 14-in. needles under the 12-in. by 12-in. cross timbers which were placed near the ends of each row of columns, even though there were only two columns in the row. Extra runs were placed near the end to take the extra wall load. As the footings for the steel columns extended below the ground surface into the basement the columns were cut off square about 4 ft. below the bottom of the floor-beams. Before removing the bases templets for the splices were applied and holes drilled in the portion above the cut, while prick marks were made on each footing. As the interior load was carried not by the cut-off columns, but by supports near it, 12-in. by 12-in. shores were placed on four sides of each column from the first floor to the second. On the shoring runways ½-in. by 6-in. steel plates were laid to receive the load from the 12-in. by 12-in. runners, 6-ft. long, under which were placed two similar steel plates turned up at the ends. There were 16 of these runners on each of the 19 runways and about 2,000 of the 3-in. steel rollers 2 ft. long. More than 1,500,000 ft. of 12-in. by 12-in. timber was used in the raft and shoring.

The blocking on the sandy ground rested on 6-in. by 8-in. ties laid close together with the material tamped under them as for a railway. Above these a blocking consisting of planed 4-in. by 10-in. timbers, and 6-in. by 8-in. or 6-in. by 6-in. cross-ties shimmed up to the bottom of the two 12-in. by 12-in. runway timbers, was used, the track plates being laid on the top of these last.

The pull was applied to six points at the rear of the building by 2-in. plough steel wire cables passed round the 14-in. by 14-in. timbers of the raft. Two loops in the centre permitted shackles to be attached at three points in the main cable. To these three shackles were attached triple blocks having seven strands of 1-in. wire rope leading 100-ft. away to the opposite blocks attached to a deadman. From the triple blocks a luff was made to double blocks, also attached to the same deadman, and a second luff, with a single block giving three strands of the 1-in. rope ending in a ⅝-in. cable, led to the drums of the hoisting engines used. The strain on the ⅝-in. cable was about one foot.

On the average the structure was moved 40 ft. each day, but the time actually spent each day in moving was only 30 minutes, the remainder of the time being taken up in carrying forward the runways and rigging the tackle and blocks. The building was moved a short distance and then turned slightly less than 90 deg. about the centre of the front wall as a pivot, after which the movement was in a diagonal line. It was again turned through almost a right angle, so that in its new position it faces in the same direction as before moving.

SLAG TAR MACADAM.

Slag tar macadam is a material very graphically described by its title. It consists of an improvement upon the early idea of tar macadam by the employment of a specially prepared furnace slag in the place of the usual road metal. In describing this product, it is stated that the metal consists of specially selected blast furnace slag, broken to standard gauges, mixed with selected tar and other ingredients, and specially treated for quick hardening by the com- [illegible] specially designed machinery, and stocked to mature. It is [illegible] nature and class of traffic, and the surface treated with fine [illegible] opening the road to traffic. After a period of from one to three months when the surface has become completely [illegible] little greater than that of an ordinary macadam road, whilst [illegible] slippery.

THE PROBLEM OF STREET CLEANING.

IT is not possible for anyone to give intelligent advice about the cleaning of the streets of any city without a pretty full knowledge of all the local conditions involved. The kind and state of repair of the pavements, the traffic to which they are subjected, the facilities for disposing of street sweepings and rubbish, the climatic peculiarities, the degree of cleanliness it is desired or expected to maintain, as well as numerous other local circumstances, are all elements that must be known and carefully considered in outlining a program for the street cleaning department. One attempting to write on the broad subject must, therefore, confine himself largely to principles and practices of general application. As an article of this nature much of instruction and value is contained in a paper appearing in a recent issue of *The American City*, and written by Mr. S. Whinery, Consulting Engineer, New York City. The article is as follows:—

In most cities the data on street cleaning afforded by local past experience and results afford the best basis for future projects and programs. While the methods followed and results obtained in other cities may be, and should be, studied, it must be kept constantly in mind that it is not wise or safe to base conclusions upon such data without a full knowledge and careful consideration of all the facts and conditions affecting them. This is particularly true of reported cost data, for in addition to differing physical conditions it is, unfortunately, true that the present methods of accounting in many street cleaning departments make it next to impossible to ascertain the actual or relative unit cost of the various details of the work, and to compare intelligently results in one city with those in another.

Finances.—In a project for cleaning the streets of any municipality, the first important practical step is to provide the necessary funds for the support of the street cleaning department. Other things being equal, the cost of cleaning the streets is, roughly, in direct ratio to the degree of cleanliness attained, and the amount appropriated will, therefore, control the quality of the work that can be accomplished. However careful, efficient and economical a street cleaning department may be, the quantity and quality of the work accomplished will be limited by the amount of money available for the work. It is illogical and unreasonable to expect a street cleaning department to keep the streets ideally clean when the amount of money allowed for the work is wholly inadequate to accomplish that result. Therefore, in considering the sum to be appropriated, the standard of cleanliness it is desired to attain should be first determined and the appropriation figured accordingly.

Money is required by the street cleaning department for two general purposes—the proper equipment of the department and operating expenses. The former is as necessary and important as the latter. Satisfactory results cannot be expected if the department is compelled to do its work with insufficient, antiquated and dilapidated apparatus. Every citizen engaged in conducting a private business enterprise appreciates the importance of procuring the best and most efficient machinery and appliances if he hopes to succeed in these days of sharp competition. He must be prepared to conduct his business and turn out his product at the lowest possible cost, and to do this his equipment must be up to date and the best of its kind. It is not unusual in large and successful industrial and manufacturing establishments that a comparatively new and costly machine will be discarded and scrapped, and replaced by an improved one that will turn out work at a lower cost, and thus prove more economical in the end. Few will deny the wisdom of the same policy in conducting municipal public work, and yet many street cleaning departments are compelled to get along with old, dilapidated and inefficient apparatus, and often not enough of even this is on hand to do the required work properly. It is wholly unreasonable to expect a department to accomplish satisfactory results either as to quality or cost of work under such conditions. Not only this, but it is, in the end, an inexcusable waste of the public money. It is a policy that may be truly called penny wise and pound foolish.

If expenses must be held down to a certain limit, it is wiser to curtail operating rather than equipment expenditures. In fact, the total expenses of the department may not infrequently be reduced by properly providing it with improved, efficient, labor-saving apparatus, even though the first cost may seem high.

While extravagance should be rigidly opposed, and while the financial condition of a city may make it necessary to restrict expenditures in all municipal departments, it must be borne in mind that if clean streets are desired or expected, the necessary money must be supplied to accomplish the purpose, and if this is withheld the street cleaning department should not be held responsible for the unsatisfactory condition of the streets caused thereby. Emphasis is here given to this matter of adequate appropriations, because in many cities where economy is felt to be necessary the street cleaning department is among the first to be attacked and to have its appropriations restricted or reduced.

Method of Cleaning.—It is coming to be generally recognized that from both the sanitary and business point of view the most objectionable part of street dirt is the fine dust produced by the drying out and pulverization of the animal excreta and other matter that finds its way to the surface of the streets. The fresh, raw and usually damp excreta and rubbish are objectionable mainly to the sight, but when dried and ground the dust floats in the air when disturbed, and disease germs contained in it are breathed into the nose, mouth and lungs of those exposed to it, where it may develop specific diseases. This dust, carried by the winds, enters residences and business houses to the injury of delicate goods or furnishings, and by reagitation may thence be carried into the human system. Any system of street cleaning that does not provide for the prevention or allaying of street dust cannot, therefore, be regarded as satisfactory. The best remedy against dust is to forestall its formation by removing the fresh material from the street as quickly and completely as possible before it can be converted into dust. Where the street surfaces are of such a character as to admit of it, the most effective method of accomplishing this is prompt removal of the accumulations by the so-called patrol system, where a limited area of street is frequently passed over by a patrolling cleaner and the fresh accumulations removed.

Sweeping by power sweepers at intervals of one or more days, while less expensive, is far less efficient and satisfactory, though if properly done and supplemented by sprinkling with water or oil at intervals sufficiently near together to prevent dust-flying, it serves a good purpose. But whatever method for primary cleaning is adopted, the formation of more or less fine material cannot be wholly prevented, and it is important that the street surface shall be frequently washed by the use of hose, flushing wagons or power squeegees. On well-paved city streets the most efficient and satisfactory method of cleaning so far devised, with the apparatus now available, is hand cleaning by the patrol system

during the day, followed by washing with hose or flushing wagons, or scrubbing squeegees during the night. While this is somewhat more expensive than plain machine sweeping, no other method yet devised will produce equally clean streets at a lower cost.

On macadam-surfaced streets this method is, of course, not applicable. With these, periodical removal of the loose material with hoes, brooms and shovels from street surface and gutters, and sprinkling in dry weather with water or oil to keep down the dust, is about the best that can be done.

Street Cleaning Apparatus.—The street cleaning apparatus now available and in general use is, as a rule, rather crude, inefficient and uneconomical. It may safely be said that street cleaning apparatus has not kept up with the march of improvement in other lines of work. The present machinery and devices may not admit of much further improvement, but there would seem to be a very promising field for the invention and introduction of new and perhaps novel devices that would do the work not only better, but more economically. The application of mechanical power to street cleaning machines and to conveyances for disposing of street waste has not made the progress that might reasonably be expected.

The disinclination of the average city council to supply the money to purchase and experiment with new and improved apparatus for the street cleaning department is doubtless largely responsible for present backward conditions. The wide-awake superintendent will keep his eyes open to possibilities in this direction, and the wise municipal government will give him authority and means to try out promising improvements.

The particular apparatus and devices most suitable for use in any city will depend materially on the local conditions, and must be selected with reference to these, and as the result of trial and experience.

Organization and Labor.—Assuming that the head of the street cleaning department is competent and knows from experience the local conditions and requirements, he should be given a free hand in the organization and manning of his department, unhampered by personal or political influence. This is a principle that has been discused so thoroughly and is so universally accepted in theory that it need not be enlarged upon here. Unfortunately, it is too frequently ignored in practice. If the head of the department is to be held responsible for results, as he should be, he must be given full authority in the selection of subordinates down to the laborers on the street.

It is the custom in many cities to make the street department a sort of asylum for those requiring charitable help. Unfortunates who, because of age, decrepitude, disease or other causes are no longer able to obtain employment in private concerns and must be, partly at least, supported by the public, as well as those who have become old and infirm in the city service, are forced upon or retained in the street departments with the idea that they can thus earn something toward their support and to that extent relieve the public of their care. It is a mistaken policy. Not only are these disabled laborers unable to earn the full wages usually paid them, but they are a demoralizing element in the whole labor force. The average laborer, however strong and capable he may be, reasons that he should not be required to do more work than those around him who receive the same pay, and will too often gauge his efforts accordingly. A few decrepit men, who are physically unable to do a fair day's work, may set the pace for a whole gang.

Where it is not possible to wholly segregate to themselves these old and infirm laborers, it will usually be far better and more economical to send them to some retreat, and to retire deserving, worn-out employees on a pension. Street cleaning work requires able-bodied, energetic, active and alert labor, and if men of that kind only are employed the whole force may be held up to a reasonably high standard of performance.

Disposal of Street Sweepings and Waste.—In most cities the final disposal of the sweepings and waste collected from the streets is a more or less troublesome problem, and the cost is no small item in the expenses of the street cleaning department. A few cities are able to dispose of a part of the sweepings from paved streets to farmers and gardeners in the near vicinity on terms that repay at least a part of the cost that would otherwise have to be incurred. But the expense of handling and transporting the material to any considerable distance, and its great bulk compared with its commercial value as a fertilizer, place a limit on its disposal in this way. Nevertheless, it should be possible, in the smaller cities at least, to interest farmers and gardeners in the use of this material to a greater extent than is now common, and to thus dispose of sweepings at a price that would reduce the cost of disposal otherwise. While the percentages of fertilizing elements in the sweepings even from smooth pavements are small, the actual market value, measured by the total quantity of these elements in a ton of sweepings, is seldom less than two dollars, and there ought, and doubtless sometime will be, some way devised to utilize or recover at least a part of this value. Mine tailings containing much less value per ton are profitably worked over and the value recovered, and it would seem possible that the less difficult and refractory street sweepings might, if the proper process could be discovered, be treated with equal success. It is a problem that deserves more study than seems heretofore to have been devoted to it.

The use of street refuse for filling low ground or reclaiming areas of shallow water and marshes has not received the systematic attention it deserves. If, where such lands are available, the city would acquire them by purchase to be gradually filled in with city waste, their value would in time be so greatly increased that the profits from their sale would go far toward paying the entire cost of waste disposal. This is not a random statement; there are instances where private persons or corporations, having contracts for the disposal of city waste, have made enormous profits by the intelligent application of this plan.

Too often cities are satisfied to obtain permission for the free dumping of such waste on private lands, the owners of which, in time, reap large profits therefrom.

There is, it is true, a feeling in the minds of the public that extensive dumps of street waste in the vicinity of built-up sections is not only insanitary, but may result in a public nuisance. Experience in a number of cities seems to prove that this prejudice is without foundation in fact. Dumps of street sweepings, if properly and intelligently handled, may be neither insanitary nor offensive. When spread in comparatively thin layers and in that condition exposed to the oxidizing effect of sun and air, the purest and richest street sweepings (free from garbage) will not create a nuisance.

Cost-Keeping and Accounting.—Until quite recent years little attention was given to accurate accounting and detail cost-keeping in the street cleaning departments of American cities. It was difficult, if not impossible, to ascertain from the records and books the unit cost of any particular detail of the work. Discussion and agitation have of late years led to great improvement in this respect in many cities.

It is coming to be more and more appreciated that in the present developed state of the business of street cleaning, improvements and economies must be looked for in more careful attention to details, and in the possibilities of small reductions in the unit cost of these details. To do this successfully requires a careful study and analysis of these details, including their fully itemized cost, which in turn requires a full and complete recording and accounting system.

It is desirable for many reasons that a uniform system of accounting for street cleaning departments should be worked out and generally adopted, but even were this done there would remain many exceptional details in each city, not covered by the general account, that require special study because of local conditions. While, therefore, an adequate general system of accounts should be adopted and maintained, a program for the collection, recording and analysis of such particular details or features of the work as may seem to have a bearing upon problems and conditions peculiar to that city should be mapped out at the beginning of the year and put in force. Any additional expense that this may involve is almost sure to be many times repaid by the increased efficiency and economy that a study of the results may make possible. What is here suggested is the application to the street cleaning department of the special detail investigations upon which the modern "efficiency studies" have been based and from which such important results have been in many cases attained.

PRODUCTION OF ASBESTOS IN QUEBEC.

Returns received from eight producers show an appreciable increase in the shipments of asbestos from the producing centres of Thetford, Black Lake and Danville, Quebec.

None of the East-Broughton properties were re-opened during the year; at Robertson, only one mine was in operation. The fibre of the East Broughton rock is short and its market value is low, but, on the other hand, the percentage of fibre recovered from the rock is high. The quality of the rock at Robertson stands intermediate between that of Thetford and of East Broughton.

There has been a marked improvement in the asbestos market, and although the conditions are not yet ideal, they are more satisfactory than they have been for several years. The working margin of profits in the asbestos industry is narrow. Taking last year's figures, the production, i.e., the asbestos extracted from the rock, totalled to a value of $3,578,007. This is of course allowing the same prices for the stock on hand as for the shipments sold. This value of asbestos was extracted from 2,527,410 tons of rock. It is true that 25 per cent. of this rock goes direct to the dump and is not treated in the mill, but nevertheless, all of it has to be quarried and hoisted to the surface from depths reaching over 200 feet. Therefore, at that rate, each ton of rock yielded $1.42 of asbestos. In 1912, this figure was $1.38 and in 1911, it was $1.53.

IRON IN QUEBEC PROVINCE.

The iron ore and iron smelting industry has been dormant in the province for over two years. There has been no production recorded since 1911, and the prospect for a resumption of activity is not of the brightest. The Canada Iron Corporation, which operated charcoal furnaces at Radnor and at Drummondville to treat the local bog iron ores, has placed its affairs in the hands of a receiver, pending a reorganization. The abolition of the government bounties on iron and steel is said to have been one of the main causes of this state of affairs.

Titaniferous iron ore, of which there was an output of 4,981 tons in 1913, comes from St. Urbain and from Ivry. It is used as an ore of titanium, of which element it contains from 18 to 30 per cent.

MANAGEMENT ENGINEERING APPLIED TO A HIGHWAY CONTRACTOR'S ORGANIZATION.*

By Henry B. Drowne,

Instructor in Highway Engineering, Columbia University; Engineer, Lane Construction Corporation.

THE fact that highway construction work looks simple and that only a relatively small amount of capital is required has led a large number of people to enter the field of highway contracting. Of this number some make a success, while others are a complete failure. Unfortunately, the law of the "survival of the fittest" does not always apply, because there are instances of those who survive through the medium of dishonest work. Competition in this line of work is very close. The big contractor with large plant equipment and heavy overhead charges must meet the competition of the small contractor who has plant enough to work only one job at a time and probably personally superintends the work. There is another class of contractors who make competition particularly discouraging at times by ignorantly bidding work at figures all out of proportion to the actual cost. This last class, however, is rapidly eliminated after trying to do work for which the bids have been too low. On account of the above conditions a contractor, who operates on a larger scale, must have a sound system of management or otherwise he will be forced out of business.

The writer believes that any man or association of men who desire to enter the field of contracting should first incorporate, as there are several advantages gained thereby. An incorporated company would usually have as officers a president, vice-president, treasurer, secretary and general manager. There might be a man for each office, or one man might occupy several of them, depending upon the size of the corporation.

No attempt will be made to outline in detail the duties of the individual officers of the corporation. Suffice it to say that at this point there should be two main divisions of duties into what might be called office work and field work. The office work would include all financial transactions of the company, such as obtaining credit, purchasing bonds, insurance, machinery and supplies and all accounting incident to the performance of the business of the company. The field work would include securing contracts and the planning and supervision of all construction work. The work pertaining to the first division is of a most important character and wise management and sound business in this department are in a large measure responsible for a company's success. On account of the brevity of this paper no further space will be devoted to this department. Consideration will be given to the management of the field work, that part of the work which is of more particular interest to engineers.

The generally recognized principles of good management are four in number and may be briefly stated as follows:—

1. The equal division of responsibility between the management and the workmen.

2. The development of a science for each element of the work.

*Presented before Section D of the American Association for the Advancement of Science at the Atlanta meeting, December, 1913.

3. The selection, training, teaching and developing of the workmen.

4. The co-operation of the management with the workmen.

Briefly stated, these rules may be applied as follows:

Usually the field work would be under the direct control of the general manager. A primary requisite to success is the ability to get contracts that will prove to be desirable work. It is difficult to make a poor job pay even under the best system of management, although an intelligent contractor will sometimes take one in order to keep his organization intact.

Second to securing desirable work would be the formation of the organization by means of which the construction work can be done. The building up of the field organization would be part of the duties of the general manager and its personnel is important. It is necessary to carry a permanent force that can be depended upon from year to year, this part of the organization comprising engineers, general superintendents, superintendents, foremen and skilled mechanics. The size of the permanent force would vary, depending upon the amount of work undertaken. In a progressive company the permanent force keeps growing proportionally to the increase in business.

The general manager should personally or through his immediate assistants, engineers or general superintendents, keep in close touch with each contract under construction. When a contract was secured, the machinery and tools necessary to do the work would be shipped to the job. Careful planning will save money that would otherwise have to be spent for new plant, as it frequently happens that some special machine can be worked to advantage on several jobs in the same season. The purchase of all material and supplies of any large amount would be done by those in charge of the office work, subject to the direction of those in charge of the field work. A superintendent, together with foremen and skilled mechanics would be selected to do the work and the approximate number of laborers necessary to start work would be determined upon. Questions arising relative to the interpretation of specifications, disputes with the party for whom the work is being done, estimating the amounts of work accomplished and the general planning of all the work would be attended to by either the general manager or his immediate assistants.

The foregoing shows to some extent the duties and responsibilities that would be assumed by the management. The superintendent who is assigned to carry out the plans on a contract would be selected on account of his fitness to do that particular job. Every man has his limitations, and it is the knowledge of these limitations that enables a successful manager to place a man where he will make good rather than to place him where he will be a failure. Besides being a man of energy and resource, a superintendent should be a man of good character. A contractor's reputation rests to a considerable extent in the hands of a superintendent and a reputable contractor values in no small degree his reputation for doing honest and thorough work. The superintendent would be responsible for carrying out the work pursuant to the plans laid down by his superiors. Delayed shipments, breakdowns, weather conditions, change of plans and labor troubles all combine to interfere with plans made in advance and the superintendent would often have to use his judgment in dealing with such occurrences until he can get in touch with those in charge of the field work. The co-operation of the superintendents, the foremen and skilled mechanics should always be sought in improvising methods to do the work in the most efficacious and economical manner.

The superintendent and his foreman should use considerable care in selecting laborers to perform different parts of the work and have considerable patience in training them to do it. An efficient gang can be developed only by a continual process of weeding out the poor laborers and the proper selection and training of those remaining. Fortunately many laborers consider highway construction as a sort of trade and they follow the same line of work year after year. If treated right they will seek employment with the same company each season, so there is generally a nucleus of experienced laborers available.

A good superintendent should always be cognizant of the cost of the work of each of his gangs and know whether the cost is out of proportion to the work that they are accomplishing. The gangs are never so large but that frequent inspection during the day and some mental calculation serves to show how work is progressing. Frequent visits by those in charge of field work would prevent slight errors on the part of the superintendent from becoming serious. Some companies require the superintendent to send to the office each night a daily report card showing the daily costs of doing the work. The writer believes that with a good class of superintendents who have the benefit of frequent conferences with those in charge of the field work the daily report card is not worth the trouble. The superintendent should, in any case, divide the work of the day under several classified heads which would be determined upon by those in charge. If a report of these classified costs for each day was sent into the office only weekly or even semi-monthly, it would prove to be efficient.

The fourth rule, that embodying the co-operation of the management and the workman, is particularly important to all highway contractors' organizations. Construction work of this kind only lasts two-thirds of a year, yet it is remarkable how a reputable contractor will maintain his permanent organization from year to year, even though his men are beyond his control for four months. The management must make the men feel that good and faithful work is appreciated and be quick to show it. Even the common laborer should not be forgotten. Although a bonus or other system of increased wages is rarely used by a highway contractor in dealing with his common laborers, the latter should be shown that those who excel gain the reward. Their efforts may be stimulated by seeing the cases of others of their class who are receiving increased pay or have been promoted to the position of foreman.

In concluding, the writer believes that the basic ideas contained in the principles of good management previously mentioned in this paper, are fully appreciated and are put into practice by the intelligent and successful contractors.

[illegible] gation engineers, the Lower Bari Doab Canal, the third section of the "triple canal project" in the Punjab, has just been completed, and is described thus in the engineering supplement of "The Times," London, England:—"The Lower Bari Doab Canal is unusual in construction, for it actually [illegible] an area equivalent to two-fifths of the whole cultivable area of Egypt. The great Punjab canals have done more, for they [illegible]

DOUBLING THE LOAD CAPACITY OF AN OLD IRON RAILROAD VIADUCT.*

By W. T. Curtis,
Contracting Engineer, Wisconsin Bridge and Iron Co.

In 1888 the Chicago and West Michigan Railway Company built a wrought iron single-track viaduct across the Manistee River, located about 100 miles north of the city of Grand Rapids, Mich., at a point now known as High Bridge, on the Pere Marquette Railroad, which system absorbed the old C. & W. M. Ry. some years ago. This viaduct is 1,170 ft. long, consisting in the main of 14 tower spans 75 ft. high by 30 ft. long, supporting 45-ft. spans between towers, and one 150-ft. river span across the main channel of the stream. The 30-ft. and the 45-ft. spans were, in the original construction, simple deck plate girders spaced 8 ft. on centres. The river span consisted of ordinary 150-ft. deck trusses spaced 14 ft. on centres. This structure as built 25 years ago, appeared as shown in Fig. 1.

During the winter of 1911-12, the structure was reinforced for heavier loading and stands to-day as appears in Fig. 2, taken from about the same point of view as Fig. 1. A comparison shows the reconstructed bridge to be somewhat more massive and substantial looking than the original. Fig. 3 is from a photograph taken at a little closer range after reconstruction, in order to bring out more clearly some of the details.

The original structure was designed for a loading about equal to Cooper's E-25. The rolling stock gradually became heavier and heavier, so that in later years the bridge was somewhat overloaded. In 1911 it was decided by the railway company to put still heavier loading (E-50) on the bridge, thus increasing it to an extent which would be unsafe for the old structure. It remained either to replace the structure with a new one, or to reinforce it, and the latter method was selected as being much more economical.

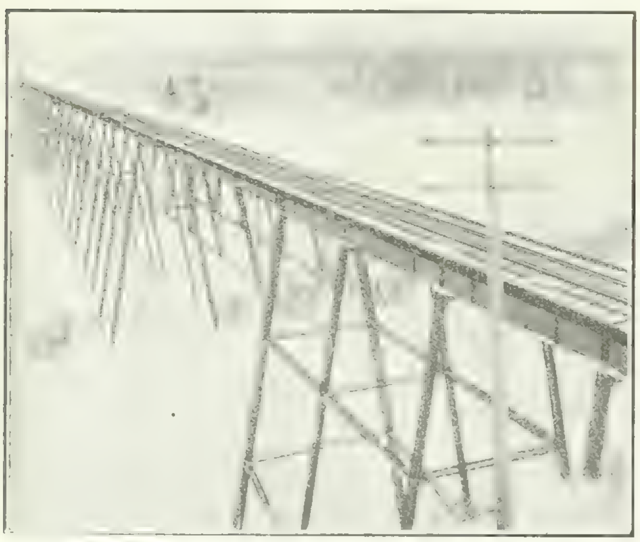

Fig. 1.—Viaduct Before Reinforcement.

Mr. J. F. Deimling, chief engineer, P. M. Ry., asked for competitive propositions for both cost and design on the reinforcement, submitting, by way of suggestive information, a solution which had been used some years ago on their Mill Creek trestle. This consisted of adding a new line of deck plate girders the entire length of the viaduct on the centre line of track, these girders being supported on new independent posts at the centre of each bent.

Some tenders were offered on this centre girder scheme of reinforcement for the entire Manistee viaduct, but were discarded, partly on account of greater cost but chiefly on account of uncertainty of distribution of load among the three girders, as the old girders of this Manistee viaduct are only 8 ft. centres, making the wood ties so short and stiff as to cause a marked degree of indeterminateness of the distribution of the load among the three girders. A further objection was the rocking or tipping effect over the new centre girder as a fulcrum under imperfectly adjusted or worn ties, the shortness of the ties magnifying this difficulty. (The girders of the old Mill Creek trestle were spaced further apart, which made the new middle girder idea less objectionable in that piece of work.) A still further objection to this centre girder scheme of reinforcement was the fact that the erection would seriously interfere with traffic during a long period of time.

Fig. 2.—Viaduct After Reinforcement.

Another scheme considered was to reinforce each of the old legs of the bents by adding another member parallel to it, surmounted with an additional new track girder placed closely along the side of the old girders, making a total of four girders with the old ones. This scheme was discarded as being prohibitively expensive, and somewhat unsightly as giving a pronounced appearance of being patched up.

The scheme finally adopted was proposed by the Wisconsin Bridge and Iron Company, being original with the writer, and is shown in Figs. 2 and 3, and also in diagram form, Fig. 4. The latter shows, in dotted lines, the old or original structure, and in full lines the newly added members.

This design was adopted for its economy, its lesser degree of indefiniteness of distribution of loads, its far greater general stiffness, its minimum interference with traffic during construction, and incidentally on account of its having a less patched-up and made-over appearance than either of the other schemes offered.

*From a paper to the Bridge and Structural Section of the Western Society of Civil Engineers, and appearing in the December Journal of the Society.

The governing or fundamental idea of the adopted scheme was to convert the upper or deck portion of the viaduct into a series of deep lattice trusses, of which the old girders would themselves constitute the top chords. This was done by adding a bottom chord about 12 ft. below the girders and introducing a Warren web system between the two chords thus formed. These old deck girders are, of course, stiff enough to resist the bending action of the load, and to deliver these local loads to the

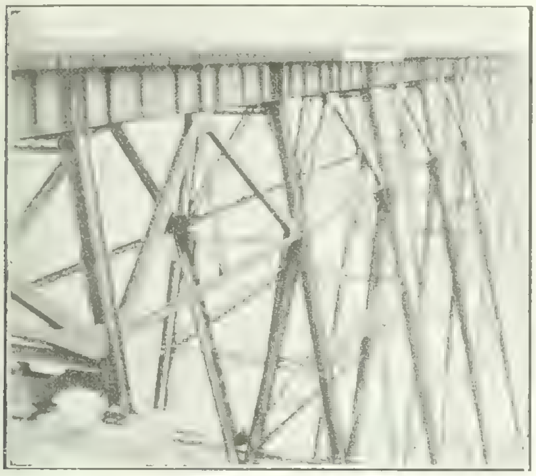

Fig. 3.—Detail of Reinforcement.

panel points of the newly formed truss. In calculation, for safety, the old girders were figured both as simple spans between new panel points, and as continuous girders, the worst result being used in all cases. Additional stiffeners were added and cross frames installed, as shown on Fig. 5.

pier built at the centre of each old bent. The two new columns thus form a V and make the remodelled bent consist of two A-frames, as shown in the typical cross-section sketch at the bottom of Fig. 4, and as shown quite clearly in perspective in Fig. 3.

This construction has the desired effect of virtually lessening the height of the trestle by about 12 ft., for the load is now delivered into the towers at the bottom chord of the newly formed trusses (Fig. 3). Furthermore, this system braces the structure longitudinally by virtue of the depth of the new trusses. Also, the new A-frame form of the bents stiffens the structure transversely. The scheme has the further advantage of being capable of field construction with practically no interference with traffic, as the old girders were not disturbed, except for the drilling of holes, etc., in them.

In this manner we preserved for the main length of the viaduct the original two-point bearing for the ties, which is undoubtedly the best, giving absolute definiteness of load delivery, and doing away with the tendency to tipping or teetering of the ties.

At the river span the system just described could, of course, not be followed, and here a new deck truss 150 ft. long was placed midway between the old trusses. The distance between the old trusses is 14 ft., being thus sufficiently far apart to give longer and consequently more limber ties, permitting of more definite proportioning of loads as delivered from the ties into the two old and the one new trusses, and also minimizing the tipping effect of the ties. In fact, this appeared to be the only reasonable solution of the river span problem, and was the one contemplated in all proposals offered.

The load from the new centre river truss is carried to the ground by a new independent straight column, as shown in Fig. 2.

The towers supporting the river span, and the three short spans of the north approach to the river span,

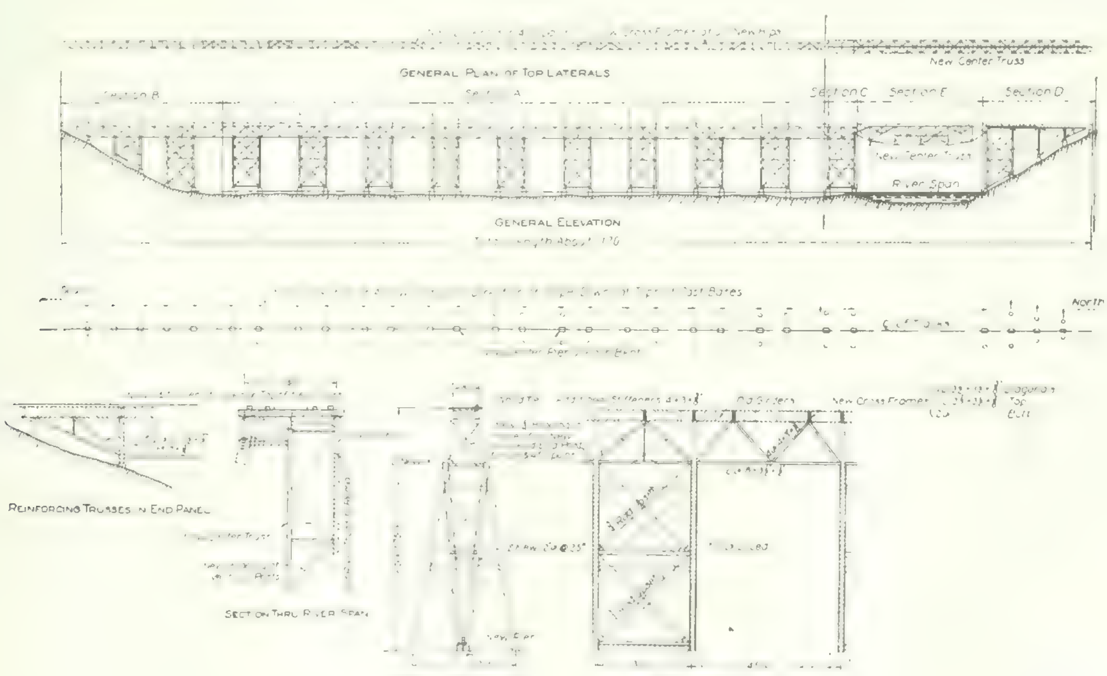

Fig. 4.—Elevation and Section Details of Bridge Before and After Reinforcement.

To carry the excess load from these newly formed trusses to the ground, two new columns are added to each bent, starting at the bottom chord of the new trusses and running on an incline down to a new concrete

were originally built with the deck girders spaced 14 ft. centres, the same as the river span trusses, and we therefore reinforced this small portion of the viaduct after the manner of the old Mill Creek trestle, i.e., by

the introduction of a new girder midway between the two old ones, in line with the new river truss and, like the latter, supported by a single new independent straight column at the middle of the old bents.

The new steel was figured as closely as possible in accordance with the American Railway Engineering Association specifications. The old metal, which is of iron, was figured in general at 14,000 lb. per sq. in. in tension, and at 16,000 — 70 l/r in compression. Judgment had to be exercised at all times in the application of specifications, this particular piece of work being most highly susceptible for the practical adaptation of that familiar remark which appears on the front cover page of all of Mr. Theodore Cooper's specifications, reading as follows: "The most perfect system of rules to insure success must be interpreted upon the broad grounds of professional intelligence and common sense."

In a remodelling work of this kind it is impossible to escape entirely, indeterminate features, as the engineer is confronted and restricted by conditions as they exist. He necessarily lacks the freedom of ingenuity offered on new work. The problem before us was to double the capacity of the structure, and the general aim throughout was to arrange the new parts so that the old parts would still carry their full share of the old E-25 loading, and so that the new members would make up the difference to bring it up to E-50, with sufficient excess to insure taking care of uncertainties.

One source of indeterminateness which was true of both of the schemes seriously considered was the possibility of improper distribution of load between the two old and the one new piers of each bent. This is always true in the case of a continuous three-point bearing, but there was no alternative in this problem, as there seemed to be no other way of getting sufficient bearing in the soil than to introduce the new middle pier. As a partial insurance to a proper distribution of loads on the three piers, the new middle pier was surmounted with an adjustable cast iron base, so simple in its adjustment that a bridge inspector on his annual inspection can, without any assistance whatever, and with no other tools than a good-sized wrench, adjust this shoe to take care of any difference in shrinkage or settlement which may appear among the three piers. The sliding surfaces of these adjustable shoes were coated with a cheap and lasting form of lubricant. The wedges provide for a vertical movement of ⅛ in. for a horizontal movement of 3 in. and are controlled by ordinary machine bolts with double nuts. In erecting the wedges, they were set in pairs with the slopes in opposite directions so as to neutralize each other and prevent the entire structure from tending to drift or slide all in one direction.

In Fig. 5 is shown sectional views of the cross frames and hangers between the two old river trusses and the new truss, the latter being somewhat deeper than the old ones. The heavy I-beam shown at the top of the new centre truss does not constitute a part of the top chord section proper, it being merely a continuous filler and tie support, in order not to permanently disturb the old top lateral system which was left intact. An entirely new lateral system was added below the old system in the plane of the new top chord. The old laterals are allowed to pass through holes in the web of this 15-in. I-beam, only one of the old lateral members being disconnected at a time to insert through this beam, and none being disconnected until the new lateral system directly beneath it was in place. This filler beam was provided with shims for adjusting it to fit the old ties.

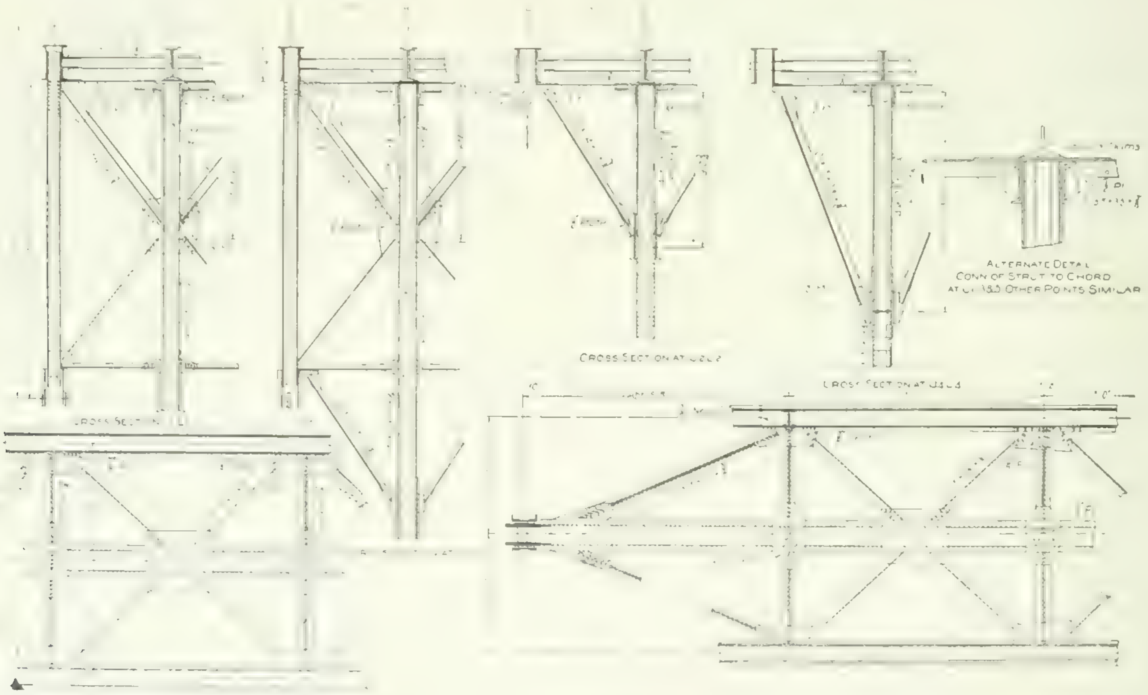

Fig. 5.—Cross Frames and Hangers Between Old and New Trusses.

A difficulty which presented itself was the difference in deflection between the old shallow river trusses and the new deeper one. This was studied carefully, and the difference in deflection was found to be sufficiently small so that it could be taken care of, to all practical purposes, by making the hangers from the old to the new trusses heavier than was theoretically required. This made the hangers act as equalizers, whereby if one truss should commence to be overstrained it would deflect enough more to deliver the load to the other truss before any actual harm would be done to the former. In this way, the load in any possibly overstrained member would

still be so much below the elastic limit load that set deformation was out of the question. It was found that the percentage of overstrain necessary to demand equalization was very low, and that while perhaps this solution of the distribution of the loads would not be considered as the most desirable practice in new designing, it served as a safe and satisfactory solution of the problem at hand.

The expansion of this new centre river truss was taken care of by a link construction, shown on Fig. 6.

The structure being narrow and high, the matter of thoroughly bracing it was nearly as important as the direct loading feature, and while the general form of reinforcement provided for a marked general stiffening of the main run of the viaduct, additional bracing was added entirely independent of the old bracing system, the old system being allowed to remain intact so that both systems are now acting jointly to withstand wind and tractive forces.

and the tractive forces are carried from this point to the ground by an entirely new system of bracing in the longitudinal plane of the legs of these new V columns. (This is shown in typical side elevation, Fig. 4.)

The solution of the more general problems, while interesting, led incidentally to problems of more minute detail, which were in themselves fully as interesting as the larger problems, and in some instances were fully as important. The detail drawings for the reinforcement of this bridge covered some 35 sheets, and the scope of this paper will permit of touching upon only a few of the more interesting details.

The new V shaped columns in the tower bents are designed to go half on either side of the old bents straddle fashion, and were shipped "knock down," each leg of the V being in two parts for each of its sections. The lacing bars were shipped riveted to one side of each section, the other side being connected in the field. It took careful drafting to insure no interference between the lacing bars of these new members and the old steel work. These new columns were connected to the old tower struts, where convenient, to form a general stiffening to the structure. In the erection of all these new columns the old steel was not disturbed, except for the necessary drilling. This, in fact, was considered as one of the commendable features of the design.

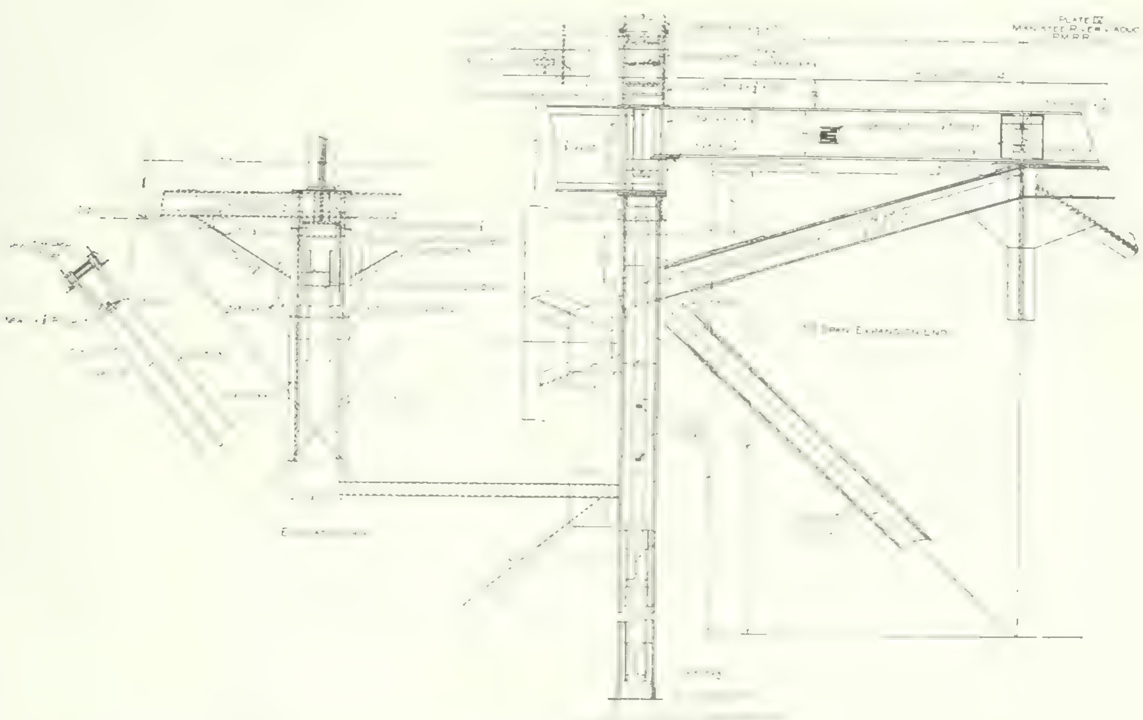

Fig. 6.—Provision for Expansion in Centre River Truss by Link Construction.

For the transverse or wind strains in the 45-ft. spans, new laterals are introduced for the middle panel of the newly formed trusses. (See Fig. 4.) These laterals terminate at new cross frames introduced at the panel points of the trusses carrying the wind load down to the bottom chord of the old deck girders, from which the load travels through a system of rod bracing in the plane of the inclined end posts of the new deep trusses to the tops of the newly formed A-frame columns. From this point to the ground the A-frames themselves constitute the additional wind or transverse bracing. The 30-ft. spans were similarly treated.

For the wind strain in the river and short approach spans which have the new independent straight centre column instead of the V shaped columns, no additional stiffness was afforded by the new column, and the old system of rods was therefore doubled.

For tractive force or longitudinal bracing the newly formed Warren side trusses formed sufficient bracing down to the tops of the newly added V shaped columns,

Connections for the rod bracing between the pairs of reinforcement trusses in the plane of the inclined end posts of these trusses presented a problem which was solved by the use of cast steel hitch brackets, which did away with what would otherwise have been clumsy and fussy detail. One of these hitch brackets is shown in position at the left-hand end of Fig. 7. In order to avoid the uncertainty of rivets in tension on these hitch brackets, bolts instead of rivets were used in the outermost holes. These hitch brackets were cut with right and left threads, permitting of direct adjustment of the tension rods.

Much trouble was experienced in finding suitable connections of the new wind-bracing rods to the old bents, which were not converted into the double A-frame form, on account of the old bracing being pin connected. Whenever possible, a connection was made, obviating the necessity of removing the old pins, but this was impossible in some cases.

Particular care was exercised to see that the loads from the new intermediate river truss were delivered properly into the columns, and a somewhat complicated detail resulted, as shown in Fig. 6, from which it will be observed that the details are so made, in nearly every case, that the old steel is not interfered with. This, in fact, was the aim of the detail work on the entire structure.

Extra care was exercised in all the details to allow for inconsistencies in the old construction. This was done by providing numerous shims and doing a great deal of field drilling that would otherwise not have been necessary. Fig. 7 shows details of the 45-ft. deep trusses under the old girders. In the upper right-hand corner of this drawing are shown shims and fillers which were provided to adjust the new steel work to the old. The entire job abounded in painstaking work of this character, in order that the new member would fit the old parts to which it should connect, and at the same time clear the old parts with which it was desired not to interfere. The detail drafting alone on this job cost a little over $950 for wages paid direct to the draftsman, exclusive of any overhead expense of any kind.

As previously mentioned, the foundations required reinforcing by the introduction of a new or third pier midway between the old piers, at each bent for the entire length of the viaduct. These piers were of concrete construction resting on piles, there being 12 piles to each of the standard bents, and 20 piles for the special piers under the new river truss. The piles were driven 35 ft. and were so arranged that they could be driven on either side of the old bent without disturbing the old iron work.

Considerable difficulty was encountered on this foundation work, due to the fact that there existed, unknown to the railway company or to the bridge company, an old corduroy road in the centre line of the viaduct for its entire length. This road was covered with several feet of sandy silt, which made it very difficult to remove the corduroy logs. In some cases the piles were driven right through the corduroy, in other cases the logs were removed, and in still other cases the logs were cut. One way seemed to be about as expensive as another.

Unexpected difficulty was also encountered on account of the water rising some two feet higher than had been previously known. This upset our calculations for cofferdams, causing much delay and expense.

The method of handling the pile driver was quite interesting. It had to be moved many times to drive the small cluster of piles at each of the bents, each cluster being split into two groups as divided by the old iron bents which stood on the centre line of each pile cluster. The pile driver was handled from the deck of the structure 75 ft. above, and was placed at the various points of operation without removing any of the old bracing. This not only saved expense but was better for the structure. The driver was picked up near its centre of gravity, tilted over with its legs uppermost and its nose or top thrust between the bracing rods of the structure to the desired point of setting up. In this way it was moved along from point to point. Very little timber bracing was used at the foot of the driver, which was guyed to the old iron columns of which there were plenty near each set-up. The engine was handled separately from the driver, not being mounted on it. This avoided the necessity of moving the engine as frequently as the driver.

The concrete was mixed and placed in the winter without any unusual expense, aside from the excavation and cofferdam annoyance previously mentioned. Gravel was brought to the site in hopper bottom cars and run out onto the viaduct to a desired point. A few track ties beneath the car were then spread and the contents dropped 75 ft. to the ice below. From the stock piles thus formed the gravel was conveyed over the ice to the final point of deposit, the mixing being done in each case right at the forms. The cofferdams were of the Wakefield type.

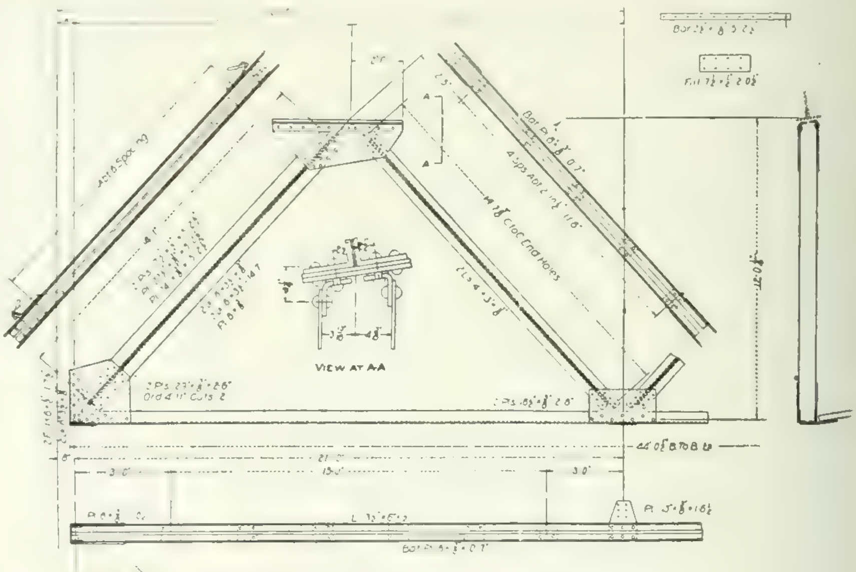

Fig. 7.—Showing Details of Trusses Placed Under Old Girders.

The weather was very cold most of the time, but we merely had to be sure that the frost was taken out of the dry material to begin with, for most of the concrete was placed under water and the small portion which protruded could be protected at slight expense with marsh grass and was kept slightly warm by the larger mass of concrete below the ice.

The erection of the steel work was somewhat unusual, and while at first appearing somewhat formidable, it worked out satisfactorily and with reasonable economy, barring delays due to foundation trouble.

The old work was mostly field bolted, which made the occasional temporary removing of old members less expensive. The field drilling and riveting was an expensive item, there being so much of it. There were about 7,000 holes to drill, about 2,000 old ¾-in. rivets to knock out and ream the old holes to 15 16 in., and about 28,700 rivets to drive on the job.

The new steel was handled by a derrick car at the beginning of the work, but this method did not prove

entirely satisfactory, and the derrick car was later replaced by a locomotive crane which gave better results.

The river span was erected with very little falsework. The new steel columns were first erected at the ends of this span. Then the top chord was raised and suspended from the old structure with steamboat ratchets, the turnbuckles being placed so as not to interfere with railroad traffic. All new top chord bracing was then placed, this being connected to the old trusses, and all bottom chord bracing removed. The balance of the new truss was then placed with falsework consisting of but a single wood post at either end, and the truss was kept suspended and controlled with 24 turnbuckles until completely riveted.

The work abounded in opportunities for interferences and misfits between old and new parts, but very little trouble in this direction was actually encountered—so little, in fact, that we were agreeably surprised, and considered this piece of work as a demonstration of the feasibility of doing this class of reconstruction at reasonable cost.

A word in regard to the condition of the old iron work may be of interest. Our erection foremen reported, early in the operation, that they found some old rivets which had to be removed; and some of the old laterals, etc., to which they had occasion to hitch stay chains, appeared to be harder and more brittle than they were accustomed to handling. This led to investigation, and a chemical and mechanical test was made on the upset stub end of a broken lateral rod, with the following observations:—

Sample A.

Manganese	0.05 %
Phosphorus	0.405%
Sulphur	0.020%
Silicon	0.289%
Area, sq. in.	0.1979
Elastic limit	not apparent
Ultimate strength, lb. per sq. in.	36,230
Elongation in 2 in.	3.5 %
Reduction of area	1.97 %
Fracture	Coarse crystalline

The above result of test was not satisfactory but the testing laboratory did not consider the sample a fair one as it appeared to have been subjected to abuse due to overloading in service, or possible burning in manufacture when upset.

Additional tests were therefore subsequently made of two samples cut elsewhere from load-carrying metal in the bridge, with the following observations, a mechanical test only being made in these cases:—

	Sample B.	Sample C.
Area, sq. in.	0.1979	0.1987
Elastic limit, lb. per sq. in.	41,230	42,300
Ultimate strength, lb. per sq. in.	50,500	57,520
Elongation in 2 in.	12%	16%
Reduction of area	12.2%	23.5%
Fracture	Fine granular	Half silky, half granular

While the metal in Sample B looked a little hard, the observations, taken as a whole, were such as to relieve suspicion as to the quality of fatigue of the iron in the old structure, and no further attention was paid to the matter other than a careful watching for defects, none of importance having been found.

As mentioned, the old structure was field-bolted (with the exception of buck and lateral bracing between the girders), a fact which was not discovered until after the field work of reconstruction had been begun. The owners, on becoming aware of this condition, at first seriously considered replacing all old field bolts with new rivets. Careful investigation showed the old structure to be in perfect alignment with none of the bolts loose in the slightest degree, although the structure had seen years of service and had been somewhat overloaded in its later years, so it was decided not to go to the extra expense of replacing the bolts with rivets. As a matter of fact, many of the buck and lateral connections which had been riveted originally, were found to be in bad shape on account of loose rivets, the vibration of passing trains having worn deeply into some of the rivets. While it was realized that the points which had been riveted in the old structure were points subject to more severe service than the points which had been bolted, the investigation satisfied all who participated in it that bolts are in reality much better than are generally considered in ordinary practice. Other observations we have had opportunity to make under somewhat similar circumstances have added evidence to this conclusion.

The cost of the reconstruction was, in round numbers, as follows; these figures including all extras on the work proper and a contractor's profit of 10%, the work having been undertaken on a percentage basis with a fixed maximum limit:—

Foundations in place (Ry. Co. furnished gravel free)	$10,200.00
New steel, 455 tons delivered at site (free freight)	22,400.00
Erection of steel (free transportation of men and equipment)	11,300.00
Total cost	$43,900.00

which, on a conservative guess, is only about half what a new structure would have cost.

The old structure weighed 496 tons.

INFLUENCE OF DRILLING HOLES ON THE STRENGTH OF SOFT STEELS.

Tests made at the Ecole Centrale, Paris, are reported in "Le Génie Civil" to show that when holes are drilled and then reamed in soft-steel bars the metal materially increases in strength, the average limit of elasticity improving 12.3 per cent. and the average tensile strength 9.2 per cent. This phenomenon is explained thus: In putting together the parts of a test piece broken under tension, it is found that the two ends do not coincide; and that, while the edges make a good contact, the central parts do not, thus indicating that the rupture begins at the centre, and that the edges have a higher tensile resistance than there is along the axis of the bar. Therefore, if several holes are drilled so as not to injure the material too much, as might be the case with punching, the average tensile strength of the section across the holes, per unit of metal, will be higher than before the holes were drilled, since each hole creates, so to speak, additional edges.

Westinghouse Church Kerr and Company, of Montreal and New York, [illegible] Railway as engineers to investigate the matter of the proposed [illegible] Tunnel in British Columbia. The investigations will cover in general the type of system to be installed, the relative economies of [illegible] fication upon operating conditions.

FLOW ON THE NORTH SASKATCHEWAN.

INQUIRIES received from some of our readers who are interested in the water power resources of the prairie provinces, respecting the stream flow on the North Saskatchewan River prompted us to apply to the Water Power Branch, Department of the Interior, for the information available at the present time.

It appears that there is a very meagre supply of data available as yet. In all, three gauging stations have been established upon the river. One of these was established in 1911 at Edmonton by the Irrigation Branch, Department of the Interior. It is stated that private interests have been taking records at Rocky Rapids, for which purpose a gauging station was established there last summer, but from this source no data are available at present. The records taken at Edmonton indicate fairly well the discharge to be expected at Rocky Rapids, as there are no streams of any magnitude entering the river between the two points; during the winter or low-water months the discharges of such streams would be negligible.

The low-water discharge has been known to fall as low as 1,200 cubic feet per second. The minimum recorded discharge is 1,073 cubic feet per second, which occurred Deember 4th, 1912, and is an actual metering. The maximum discharge recorded is 74,100 cubic feet per second, and occurred in July, 1912; though there is evidence upon which it is estimated that a maximum discharge of 180,000 cubic feet per second has occurred.

The following is the maximum, minimum and mean monthly flows recorded at Edmonton during 1911 and 1912:—

		Discharge in second-feet		
		Maximum.	Minimum.	Mean.
1911	May	21,755	6,508	9,238
	June	27,930	10,600	17,412
	July	51,442	15,520	28,094
	August	40,092	15,320	24,000
	September	18,668	8,024	11,502
	October	8,024	4,887	6,597
	November (1-10)	4,092	3,132	3,723
	December (6-31)	1,750	1,380	1,638
1912	January	1,402	1,164	1,255
	February	1,430	1,232	1,328
	March	2,620	1,062	1,316
	April	7,700	2,820	4,029
	May	16,200	4,770	11,926
	June	35,150	6,180	18,242
	July	74,100	15,000	13,900
	August	70,300	13,900	26,444
	September	23,750	7,350	12,864
	October	8,460	5,595	7,162
	November	5,595	1,504	3,177
	December	1,980	1,206	1,680

Some measurements taken in 1913 are given below:

	Discharge in sec.-ft.		Discharge in sec. ft.
January 17-18 ...	1,207	July 3	22,639
February 1	1,552	July 21	18,906
February 10	1,280	August 1	18,034
February 25	1,230	August 23	11,663
April 2	1,972	September 1	14,150
April 21	16,705	September 15	8,031
May 2	3,908	September 23	6,924
May 12	6,313	October 2	5,348
June 2-3	12,785	October 14	4,208
June 23	26,890	October 30	3,176

THE EXTENT OF MINERAL WASTE.

AN estimate of the present waste, in large measure unnecessary, of mineral resources in the country may be arrived at by a comparison with that of United States, which amounts to a loss of not less than $1,000,000 a day.

In one respect at least a consideration of the mineral wastes has a basis quite different from the consideration of agricultural wastes. Our crops represent an annual production from a reasonably permanent soil; our forests may grow again, though a much longer period of time is required; and the soils themselves may be reproduced from the subsoil and the rock beneath. But of our mineral resources we have only the one supply. This supply is to a considerable extent destroyed in use; and at the present increasing rate at which we are using and wasting it our one supply will be either exhausted or largely depleted while the country is yet in its youth.

The most urgent need for investigation and reform in the country to the south of us is in connection with the unnecessary waste of oil and natural gas. The United States Bureau of Mines reports that it has been able to stop a waste of natural gas during the past year valued at $10,000,000, with very limited facilities at its disposal. In many parts of the Oklahoma oil and gas fields the waste of natural gas that still continues is equivalent to $15,000,000 to $20,000,000 per annum, and this waste in all of the oil and gas fields of the country now aggregates more than $50,000,000 per annum. Of the total waste of gas in the different oil fields of the country more than 80 per cent. is believed to be easily preventable. As regards the remaining 20 per cent., it is believed that gasoline may be extracted from much of it and the gas itself burned for some useful purpose.

The need for enlarged investigation is further shown by the fact that in addition to this waste of gas the waste of petroleum, and especially the loss of the lighter oils, in pumping and storage is much greater than is ordinarily supposed. Moreover, the injury caused in a number of oil fields through the flooding of oil and gas strata by underground water is a separate phase of the subject calling urgently for inquiry and investigation.

The waste in coal mining is another drain which calls for serious inquiry and investigation. A preliminary estimate, based upon limited inquiry and examination, indicates an annual waste or loss of coal in mining and handling of not less than 250,000,000 tons per annum.

What is needed in connection with this loss is a thorough underground survey and examination at certain carefully selected areas in each of the important coal fields of the country, with a view to determining the exact conditions under which mining operations take place and the possibilities of adopting less wasteful methods.

There is a strong advocation of similar investigations looking to a reduction in the wastes or losses in the mining, preparation, and treatment of metalliferous ores and metals, which wastes and losses aggregate in different cases from 10 to 50 per cent. of the total yearly production of such minerals and metals.

Although the above figures apply to conditions in the United States, they sound a warning note everywhere against thoughtless waste in the eager regard for temporary gain on the part of individual operators. The saving already accomplished indicates the fruits awaiting similar methods to prevent the total and permanent losses which metal mining and metallurgical operations sometimes entail.

The Canadian Engineer

CONTENTS OF THIS ISSUE.

FOR THE YOUNG ENGINEER.

The season is drawing to the stage when the portals of our universities will open for the young graduate to pass out into the field of engineering. In his eagerness for activity of a constructive nature he is not likely to pause for an invitation to lay aside his books. He should understand at the outset, however, that in spite of its qualified instructors, rigorous discipline, specialized courses and extensive equipment, the university does not turn him out a finished engineer. It has done well if it has fitted him with an understanding of how to acquire the technical knowledge which the problems of the profession will demand as they one by one present themselves.

At this time it is appropriate to bring before the young graduate some attributes of engineers and engineering that may not have appeared on the surface during the course of his academic work. One has only to observe a view of his surroundings in the course of the day to perceive what is being done and what is still to be done in the converting of forces and materials of nature to supply the needs of the world. The engineer is the man who leads and directs the doing of it. The work itself provides his best pay in the satisfaction of its successful accomplishment. Uniting the Atlantic and Pacific at Panama, throwing transcontinental railways across the Dominion, reclaiming vast areas through irrigation, developing water powers great and small, or driving tunnels through Mount Royal and the Rockies, exemplifies the efficient and capable manipulation of forces with which engineering has to do.

In his article on another page of this issue Mr. J. L. G. Stuart has paralleled the outstanding professions of the present day, with the result that the young engineer may be justly proud of his own selection. But it should be added that the unvarying forces and principles of the engineering profession require of him the same strict integrity and attention to business that spells success in any less advantageous choice of occupation. He will learn early that the engineering world has no place for other than the energetic man. His work is to get things done.

Further, he should aim to retrieve without delay the broadness of view which forced attention to special studies has required him for a certain lapse of time to forego.

Finally, as Mr. Stuart has intimated, engineering is a progressive profession, and the young engineer must resolve to keep up-to-date. A more intimate knowledge of his own particular branch of engineering should be his chief desire, but an equally important duty to himself is to keep posted upon what is being done in a general way along engineering lines. He will find that these requirements can be best attained by close relationship with men of his profession, through personal acquaintance, engineering societies and the engineering press.

ADVANCE IN ENGINEERING EDUCATION.

Next May the School of Mines of Columbia University will celebrate its 50th anniversary and it is stated that the curriculum which has been followed for a number of years without material change will then be discontinued. Under the new arrangement three years of specialized study in the various branches of engineering will be offered leading to the several technical degrees in the Schools of Mines, Engineering and Chemistry. The requirements for admission will be the completion of at least three years of college or scientific school training.

The reason for this change is undoubtedly the outcome of prevalent opinion that in recent years something more has been necessary for the well equipped engineer than a sound technical knowledge of his subject. The engineering profession enters into almost every walk of life and the engineer should be a man not only well versed in his profession, but a man of affairs. He is called upon for advice in subjects connected with engineering to-day that were never associated with it until the past few years. Instead of being called into consultation on technical subjects alone he is now expected to give information upon matters connected with the business world in a way the engineer of a few years ago never imagined. Instead of adhering strictly to science he must now pass upon problems connected with economics, finance, and politics, and must always hold his own in the councils of men of business.

That a high school boy who comes to an engineering school is handicapped under these circumstances cannot be doubted, and the new order of things now being established at Columbia University promises a measure of relief.

It is a course which our universities with faculties of applied science and engineering should consider very thoroughly. If the engineering student could possess the basis of a general college education when he enters it is bound to help him to attain the position now demanded of the engineer and he will be better prepared to take up the harder tasks of graduate work with no necessity for apprentice work.

The completion of at least three years of a college or scientific school course as now required by Columbia for admission, this course to include thorough instruction in mathematics, physics and chemistry, and in addition, preparatory work in draughting, shop-work, mineralogy and surveying, places the student in a position to efficiently assimilate the education which there is to be derived from the demonstration and personal operation of the equipment with which our university laboratories endeavor to combine the practical with the theoretical.

EDITORIAL COMMENT.

The citizens of Ottawa have voted in favor of mechanically filtered water from the Ottawa River in preference to the 31-Mile Lake scheme advocated by Sir Alex. Binnie.

* * * *

Previous reference has frequently been made in these columns to the work of the International Joint Commission, and to the efficient methods which it followed for the consideration and solution of the variety of problems submitted to it by the governments of Canada and the United States. On April 7th the Commission will meet in Washington to resume its consideration of the applications of the Michigan Northern Power Company and the Algoma Steel Corporation for authority to divert water and to build compensating works in the St. Mary's River at Sault Ste. Marie.

Since its meeting in Detroit early in March a committee consisting of engineers representative of both countries and of the two applicant companies, have been engaged in drafting a schedule of conditions designed to provide such regulation of the dam in the St. Mary's River as will effectually safeguard the interests of the municipalities and others at the western end of Lake Superior.

ENGINEERING AMONG OTHER PROFESSIONS.

By J. L. G. Stuart, B.A.Sc.,
Assistant Engineer, Roadways Department, City of Toronto.

THE engineering profession is a very progressive one. It is always looking into the future, always trying for something a little better than it has already accomplished, always attacking new problems and doing new and bigger things. This is to some extent true of the medical profession, but it can hardly be said to be true of law, for the lawyer is always looking to the past and hunting up an old precedent to govern the administration of justice to-day. If past decisions were in accordance with the eternal verities, and had proved themselves just, beyond dispute, it would be all right, but such is not the case, for these laws and decisions were merely man-made, and the only thing that keeps a great many of the decisions standing is that they have not been carried to a higher court. In engineering, the fact that such a thing was done in such a way last year, last decade or last century, rather counts against that way of doing it to-day, for it is almost certain that there is a better way of doing it. The whole tendency of law and theology is conservative, that of engineering is progressive. In five years an engineer is almost out of date unless he has striven to keep abreast. Not so the clergyman, while a lawyer has simply to read up the last five years' statutes and decisions.

In engineering, probably more than in any other profession, a man has to stand on his own ability to do things. Fine words and fine manners do not count; it is his works that speak. In medicine, law and theology a man's personal appearance, address and general deportment count for a great deal, but in engineering the quality above all is the product of training and ability to put plans into material. Of course, if the engineer has men under him, he has to know how to handle them, but about all they require is just treatment and a knowledge on his part of what he is doing. An admirable feature is that the profession strikes such an even balance between theory and practice and gives such a scope for both inductive and deductive theory. An engineer works out his theory and translates it into material. If he does not get the results anticipated, it is up to him to discard his theory or find out what is the matter. He must keep the two together—that is to say, his theories must be practical or he is a failure in his profession. Unlike the lawyer who builds up a great deductive system of jurisprudence and frequently ends in making a travesty of justice, and unlike the theologian who also builds up a great system by deduction and arrives at a conclusion diametrically opposite to that of his brother theologian, the engineer never reaches such a *reductio ad absurdum*, for his theory is tested in practice at every step. He may make mistakes in details, but these soon show up and he need have no fear of his profession being torn asunder by the discovery that part of his understructure is false, for that understructure has already been tried and found true.

The engineer should have a good opinion of his profession. This is very easy, as it is rising in public estimation every year, and as its advantages far outweigh its disadvantages. Among the former might be mentioned its universality. Like art, its principles are independent of language, race, religion, locality and human laws. The principles which govern the boring of the Alps are the same which govern in the Rockies under similar conditions. A bridge over the Zambesi follows the same rules as one over the Niagara and may easily

be designed by the same man. But a lawyer cannot go from even one province to another without having to study a new set of statutes. Not only are the principles universal as in medicine but, unlike medicine, the language is also universal; that is to say, the plans and drawings of our bridges and tunnels, etc., can be understood by any engineer be he Hungarian, French or of any nationality. In some large drawing offices in America there are many foreigners, some of whom speak very little English, but they are adept at design and draw good pay. This gives the engineer a wide field and limits him to no special country, climate or condition of men and things.

But an engineer has to take the consequences for his mistakes. If a lawyer looses a case through some oversight or poor work he has little trouble in making his client believe his case was rather weak, if indeed, his client ever questions the lawyer about his conduct of it. And if a doctor loses a case through imperfect diagnosis or wrong treatment it is very easy to leave the relatives under the impression that it was the inevitable. But not so the engineer. If his design is at fault and a train crashes through a weak bridge, the engineer has to take the consequences. He may not be hanged for murder, but he will lose his position and his reputation. It is not often that these accidents are traced to the engineer because his designs have been all tested step by step. He is well aware of the consequences of a mistake, and there can be no shuffling on his part. If President McKinley's death had been caused or even hastened by the explosion of a badly designed piece of apparatus in his sick room, instead of by giving him solid food too soon, the engineer or designer would not have gotten off with honor.

Deception has no place in engineering. Mother Nature will bring it to the surface sooner or later.

The profession, like trade and finance, is very materialistic. Every proposition has to answer the question, "Will it pay?" While nearly every one of them adds to the wealth resources, pleasure and other uses of mankind, still it is nearly always a materialistic advantage. Furthermore, the engineer deals entirely with materialistic force and matter, rarely with life, mind and spirit. To compensate for this, his recreation would follow other lines such as art, literature and sociology.

Another disadvantage is that it is apt to make one careless of the courtesies and amenities of life. However, this is very secondary compared with the first. A more serious one is that it is very difficult to get an independent position, or in other words, to have one's own business. There are a few consulting engineers, but most of them had to make their reputations as subordinates of big companies. An engineer is apt to devote all his time to technics and neglect the financial and executive side. This is the case in nearly every engineering office, the men are good engineers but they have not enough business to manage their own prospects to the best advantage. The result is they are simply tools of men who know less than they do but are good at business and draw bigger salaries. It would pay a young engineer in the long run to spend a vacation in a hustling real estate office, or at least selling engineering supplies. At any rate, he should seek a position where he will get business ideas and practise rubbing shoulders with his equals, rather than with his superiors, for then he will naturally fall into a secondary place and that should be avoided. A certain amount of office routine is necessary, but he should try to get a position where he will have field work along with it. This is a comparatively easy thing in civil, mining and hydraulic engineering, but very different in mechanical and electrical, and perhaps metallurgical and chemical.

All things considered, engineering is a fine profession and one which is rising in public estimation year by year because it delivers the goods. It has pierced the Alps and tracked the Andes; it has driven turbine boats at 40 miles per hour, steel railroad trams at 80, electric trams at 130 to 132. It has transmitted intelligence under the ocean and through the air, it has driven ships above the water, on the water and under the water; it has mapped the earth's surface, sounded the ocean's depths and has measured the winds in order to navigate three or more miles above the surface of the earth. It has gathered minerals from refractory rocks and transmitted water from mountains to desert and city. It has converted the refuse of great cities into valuable fuel and with it has raised the standard of health. It has built skyscrapers and cathedrals, raised hills and formed rivers. It has transmitted power more than two hundred miles over a small wire and may yet do it without the use of wire. Indeed, it would be hazardous to set any reasonable limit to the things the profession of engineering will accomplish.

AIR BRAKE TESTS ON THE PENNSYLVANIA RAILROAD.

IMPORTANT improvements in the braking of heavy passenger cars were described in a paper read before the American Society of Mechanical Engineers in New York, on February 10, by Mr. S. W. Dudley, of Pittsburg. These tests were conducted jointly by the Pennsylvania Railroad and the Westinghouse Air Brake Company. The results are considered the most important recent contribution to the subject of air brakes.

A train of 12 steel cars at 60 miles per hour stores up 224,000,000 foot-pounds of energy. This is sufficient to raise the entire train 120 feet. With prevailing brake equipment such a train would be stopped by an emergency application in a distance of 1,600 to 2,200 feet, according to the truck rigging and brake shoe design. These tests showed that this distance has actually been reduced to 1,000 ft., or to within the length of the train. This was the result of improvements in the truck brake design involving the clasp brake, having two shoes per wheel, and the location of the brake shoes with reference to the horizontal centre line of the wheels, in addition to improved methods of applying the air brakes quickly and simultaneously and at a high pressure. This concerns safety.

These tests emphasized, as has never been done before, the possibilities of improvement in efficiency and economy in regular service operation by proper attention to design and installation in order to permit the realization of the flexibility of improved air brake apparatus. These improvements centre in the electric control of the brakes, giving quick, simultaneous and responsive action. The electric control has opened the way for maximum effect in practice of improvements in practically all the factors involved in air brake apparatus, all of which were covered in the development represented by these tests. The tests constituted a progressive development of brake rigging and brake shoes in connection with the scientific study of the air brake as a whole.

Trains of 15 years ago were stopped in about half the distances prevailing in the practice of to-day. Increased size and weight of equipment brought an entirely new brake problem, which these tests have solved.

CONTRACTION AND EXPANSION OF CONCRETE ROADS—II.

ONE of the very important reports submitted at the National Conference on Concrete Road Building, Chicago, in February last was that of the committee on the contraction and expansion of concrete roads. The committee consisted of Messrs. R. J. Wig, N. H. Tunnicliff and W. A. McIntyre. *The Canadian Engineer* for March 19th, 1914, published the first portion of an abstract of the report. This portion dealt with the effects of changes in temperature and moisture content of the concrete, the effect of variation in the condition and character of the sub-base and the effect of traffic. The following sections, bearing upon the application of present knowledge to the prevention of cracks in concrete roads concludes our summary of the committee's report.

Cracks.—The committee expressed its belief that it is possible to prevent all cracking of concrete in roads, with a proper understanding of the physical phenomena affecting the expansion and contraction of concrete in roadways and a proper application of engineering principles.

Longitudinal cracks usually do not occur until seasonal changes. Transverse cracks may occur at any time, but the majority should occur during the first dry season.

Transverse cracks are probably due to a favorable combination of moisture content in the concrete and atmospheric temperature conditions, together with a restraint induced by the condition of the subgrade. They may, however, be caused by an unstable foundation.

Longitudinal cracks are probably in the majority of cases caused by an unstable condition of the sub-base, although they may be caused by a favorable combination of moisture content in the concrete and atmospheric temperature conditions, together with a restraint induced by the condition of the subgrade. The latter is particularly effective if the sub-base is crowned.

Diagonal cracks are probably most commonly caused by a combination of moisture content in the concrete and atmospheric temperature, together with a restraint induced by the condition of the sub-base. In rare cases they may be caused by the above combination and longitudinal restraint along one side when abutting a rough structure.

Effect of Quality on Cracking.—The best mixture is the one which is the most dense and which will reduce to a minimum the absorption of moisture, but it should also have a strength of at least 1,500 lb. per sq. in. at the end of 28 days. It should be mixed in such a way as to give a product of uniform quality. It should be placed in such a manner as to give a uniform quality of concrete in place and to prevent loss of water.

The sub-base should in all cases be thoroughly wet so as to prevent absorption of moisture from the concrete and thus cause a rapid drying out of the concrete.

The concrete should be cured in such a way that it will retain its own moisture and receive sufficient additional moisture until it is strong enough to resist the shrinkage stresses induced by drying out.

Relation of Slab Length to Cracking.—The maximum permissible length of slabs, of similar design, on a firm foundation, on a light or flat grade will vary with the climatic conditions. In localities where there is little rainfall, as in Arizona, or the San Joaquin Valley in California, the slab length probably should not exceed 25 ft. This length has been determined by an analysis of a report by A. B. Fletcher, State Highway Engineer, of California, on the cracking of a monolithic road, together with a knowledge of the results of measurements obtained by the Bureau of Standards.

In localities where the rainfall is intermittent and the ground water rises in cool seasons and lowers in warm seasons, similar to conditions which obtain east of the Mississippi River, the slab may vary in length from 30 ft. to a continuous slab. While the 30-ft. slab may be regarded as a minimum length, from economical considerations, the results of experiments indicate that cracks are quite likely to occur under certain conditions even in this length.

The data available would indicate that the length of the slab for the same sub-soil conditions does not affect longitudinal cracking. It is, however, interesting to note that in a report by A. N. Johnson, State Highway Engineer of Illinois, is to be found a statement that in roads constructed by him in 1912 with a total length of 2.3 miles he finds 9.1 slabs per mile, cracked longitudinally, transverse joints being spaced from 50 to 100 ft. apart, on roads 16 to 18 ft. in width. A report of F. F. Rogers, State Highway Commissioner of Michigan, on the Wayne County Roads, shows that on roads constructed in 1912 with a total of 9.6 miles, 9.5 slabs per mile, cracked longitudinally, transverse joints being spaced 25 ft. apart on roads 15 and 16 ft. in width.

The length of slab should vary with the quality of the concrete. In a short time a denser concrete will absorb less moisture and consequently will have less tendency to move; it will also have greater strength to resist stresses induced by restraint of the sub-base. A dense concrete is particularly of value where subjected to intermittent wetting and drying. In a dry climate where plenty of water is not available for curing the slab length should not exceed 20 ft.

The length of the slab should not be the same for all sub-soil conditions. If the sub-soil is of unstable material the length of the slab must be shorter than for a condition in which the sub-soil is stable.

If there is a distinct variation along the length of the road in the materials of which the sub-base is constructed a joint should be placed where the change takes place. This is necessary because of the change in the frictional restraint offered by different materials and also because of the difference in the porosity which changes the moisture conditions.

The length of the slab should vary with the condition of the sub-grade. If the sub-grade could be made very smooth so that a more or less uniform frictional resistance would be obtained throughout the length of the slab, it would perhaps be the most desirable condition, but as this is not obtainable it is believed that a more or less uniformly rough sub-grade is preferable to a so-called "smooth" sub-grade. This is explained by the fact that the rough sub-grade will make each small section in the slab care for its proportionate share of the stress induced by frictional restraint, while if the sub-grade is so-called "smooth" there will be rough places in it at intervals which will place upon certain sections undue stresses, which therefore will be more liable to cause cracks. If there is any decided change along the length of the road in the condition of smoothness of the sub-grade a joint should be placed at the point where this change occurs.

If the sub-grade is so-called "smooth" on a steep grade, the permissible length of slab would not be as long as a light grade, there being a tendency to slide down hill and thus add additional stress to that imposed by moisture and temperate change.

If the grade is steep the slab should be shorter in length than that used on a flat grade. A joint should be placed at all decided changes in grade.

It would appear that the slabs could be made longer if constructed during the fall or winter, in localities where not subjected to freezing, than if constructed in either the spring or summer, although there is not sufficient data available to determine whether this would permit of an appreciable change in length. Conditions indicate that concrete laid in the fall is probably not subjected to stress as much during the first few months, since the tendency to increase in length due to moisture is counteracted by the tendency to decrease in length due to temperature.

The experimental results indicate that there was greater movement of the concrete covered with a bituminous carpet than with concrete uncovered. This is indicated in Curves shown in Fig. 1 of covered and uncovered slabs. If, upon further investigation, this condition is found to hold true the slab length would probably have to be varied. The reason for the greater movement noted is probably to be explained by the fact that a dark surface absorbs more sun heat and the bituminous coating holds for a longer period any moisture which gets beneath it.

The length of the slab may be made greater for a greater thickness of slab. The increased friction caused by increased weight is proportionately less than the increased ability of the concrete to resist stress. Sufficient data are not available to give a relative figure.

It is not believed that traffic need be considered in determining the length of the slab.

There would tend to be a greater movement in a wide or elastic joint than in a narrow or unelastic one and since cracking occurs during contraction there would be less movement with a tight joint; a tight joint therefore would permit of a longer slab. It is not known, however, that this factor is sufficiently appreciable to be considered in determining the length of the slab.

Relation of Cross-Section of Slab to Cracking.—A concrete road laid on a crowned sub-base would be the most liable to crack longitudinally and on a dished sub-base the least liable to crack. The resistance offered to contraction of a slab with a crowned sub-base is greater than that offered by either a dished or flat sub-base, because the concrete must move against the effect of gravity. With the dished sub-base the concrete contracts with the effect of gravity and therefore is stressed the least.

The cross-section having the greatest thickness at the centre with a dished sub-base would offer the greatest resistance to longitudinal cracking; the cross-section having the least thickness at the centre with a crowned sub-base would offer the least resistance to longitudinal cracking.

It is not believed that transverse cracks are in any way affected by the width of the slab. The data available to the committee would indicate that the width of the slab for the same sub-soil conditions does not affect transverse cracking.

The slab should have its greatest thickness at the centre no matter where the longitudinal drain is placed.

Over an unstable sub-soil the slab should be made of greater thickness throughout the width than over a stable sub-soil, with the greatest thickness at the centre.

It is not necessary to vary the design of the cross-section of a slab with the condition of the sub-grade.

The dished is the preferable design under all climatic conditions, especially in arid regions.

The dished sub-base is the preferable cross-section for all seasons and especially so if the concrete is laid during the dry season.

The wider the road the thicker should be the slab.

It is not necessary to vary the design of the cross-section with the length of the slab.

A concrete road which must withstand heavy and concentrated traffic must be made thicker than for light traffic.

Value of Reinforcement in Preventing Cracking.—Reinforcement will be of value: (1) When the foundations are uncertain; (2) in regions where there is little rainfall and long or wide slabs are desired; (3) in regions where there is sufficient water for curing; (4) when it is necessary to have a thin slab; (5) when a decided change in grade occurs; (6) when the movement of the concrete is restrained at street intersections or on curves, if joints cannot be placed properly; (7) when the width of the slab is greater than 25 ft.; (8) when it is necessary to crown the sub-grade and the slab can not be made thicker at the crown than at the sides.

Only fabricated steel should be used and that form which will give the greatest distribution.

The quantity of reinforcement can only be determined by an analysis of the conditions affecting each specific case.

If uncertain sub-soil conditions tend to cause a settlement on the sides of the road, which is the most common condition, the reinforcement should be near the top. If settlement is apt to occur within the centre of the slab the reinforcement should be placed near the bottom, and where the whole of the sub-base is uncertain the reinforcement should be placed near both top and bottom. Reinforcement to resist stresses due to temperature and moisture changes should be placed near the bottom of the slab. The stresses set up by a change in temperature are insignificant, except in arid regions, compared with those set up by moisture changes, and ordinarily reinforcement to provide for temperature stresses is unnecessary.

The slab length may be anywhere from 20 ft. to continuous, depending upon the many elements entering into the problem.

The widest pavement without cracks within our knowledge is 40 feet. It is probable wider pavement can be constructed.

It would appear that if properly designed a thinner slab may be used if reinforced. Definite information, however, is lacking to exactly determine this fact.

The conditions of construction affecting cracking apply to plain concrete slabs as well as to reinforced slabs.

Effect of Joints on Cracking.—The purpose of joints is to relieve the stress which might be induced by a volumetric change in the concrete caused by change in moisture content or temperature and to care for unstable foundation conditions. The committee has no evidence of the failure of slabs in concrete roads due to buckling, crushing or spalling and therefore consider the joint as primarily for the purpose of taking care of contraction.

If a concrete road is constructed without considering the affecting factors, with the idea that nature will provide cracks, it will crack, but before doing so it will cause a weakening of the concrete for some distance on each side, which may result in a partial disintegration of the road. This is evidenced by short forked cracks appearing running off from the main crack. The cracks thus formed will gradually lengthen with time and will not only be irregular in alignment but they will not be vertical.

The width of the joint controls the longitudinal movement of the slab. A greater width will allow of greater movement, consequently the slab will be more liable to crack upon contracting.

A joint should be constructed as a contraction joint with little or no room provided for expansion, as all stresses in the concrete caused by expansion are compressive and may be absorbed by the concrete; later, upon contraction there will be little movement and therefore only small tensile stresses will be induced and there will be less liability of cracking.

Experimental results show that only the movements occurring near the ends of the slab are usually transmitted to the joints.

There are no available data to show the difference in effect of diagonal and square joints on expansion and contraction. Any joint, however, should be perpendicular so as to give proper bearing between adjoining slabs when they expand.

It is necessary to provide a longitudinal joint between the pavement and an adjoining structure if the adjoining structure is rough and will cause longitudinal restraint or if the abutting structure will not offer sufficient resistance to prevent being pushed out of place.

Joints should be placed at street intersections and at sharp curves so as to allow of free movement, wherever the concrete is restrained.

Effect of Character and Condition of Sub-Base on Cracking.—A rough sub-grade is preferable since a very smooth sub-grade is impracticable to construct.

The sub-base should be very dense, but not entirely impervious. Where a rich mixture is used in the construction of a road it would tend to dry out unduly, causing excessive contraction. If a smooth subgrade could be provided so that the friction would be reduced to a minimum it might be desirable to have an impervious sub-base, but this condition is very difficult to obtain.

It is desirable to have the sub-base uniformly and thoroughly compacted so as to prevent uneven settlement.

The sub-base should be dished.

Conclusion.—The committee observed that it had been fully established that the change in moisture content of the concrete was of much greater moment than the change in temperature under normal exposure; and that a proper combination of change in temperature, change in moisture content and friction have made possible the construction of long slabs which have remained free from cracks; while under an unfavorable combination of these factors, which is to be found in certain localities, long slabs have invariably cracked.

With a proper understanding of the physical phenomena, which are recommended for investigation, and with a proper application of engineering principles by competent highway engineers, it is believed by the committee that all expansion and contraction of concrete in roads can be so controlled as to permanently avoid cracking.

FORMS FOR CONCRETE WORK

WE do not often hear of failures occurring in reinforced concrete buildings after their completion, but generally during their erection, and although all failures cannot be attributed to defective forms, yet the forms are to blame in a sufficient number of cases as to render the forms for concrete work an important element in securing efficiency in construction, and not merely in the utilitarian aspect. Although it is not the general practice for engineers to design their forms, that being generally left to the contractor, Mr. Allan Graham, in a paper which he read on March 12th before the Concrete Institute, expressed his belief that an engineer, for his own protection, should at least set out some typical portion of the forms for the contractor's guidance, thus doing all he can to circumvent failure in this direction at any rate. Of course, good forms alone will not ensure safety, and vigilance should likewise be used in detecting bad work, bad design, and bad material. For, as Lieut.-Colonel Winn has pithily put it, "a fool with a shovel may absolutely defeat the most elaborate calculation involving the calculus."

Formwork is a term embracing all kinds of moulds or centering set up to give shape to the concrete or similar plastic material. It is so employed in America. There is a consensus of opinion in favor of the definition "formwork" as an inclusive term, owing to the real meaning of the term "centering" having a more limited application than usually attributed to it. As the word "form" is the same, and has the same meaning in French, German, Italian and Spanish, the author believes it will be agreed we are on safe ground if we accept it for our purpose. The term has great merit, being superior to such terms as falsework or shuttering.

The contention that the engineer should prepare the design of formwork has much to recommend it. An engineer will generally have no hesitation in setting out the design of centering for a bridge or other equally important work, but for some reason or other the design of ordinary formwork which plays such an important part in the cost of reinforced concrete is never considered. There is no doubt that a thorough understanding of the principles underlying the everyday practice of concrete form design is one worthy of the best engineering talent. With this understood, the problem can be analyzed, the requirements realized, and the design decided upon that will be the most economical and efficient, giving due consideration to the salvage of materials.

It is not merely that a design is required for a specific case which will safely support a certain volume of concrete, it is rather the problem of designing a set of forms which can be erected, taken down, and many times re-used during the progress of work. The factors involved are many, such as the type of centering, the kind of timber, how much to centre at one time, and what clamps, bolts, nails, wire or strap steel should be used. These things properly considered will repay the trouble taken and result in better and more economical work.

Various authorities place the cost of formwork at anything from 20 per cent. to 60 per cent. of the total cost. The possibility of reducing this hindrance to the more general use of concrete ought to be sufficient inducement for us to give the matter close consideration. American constructional firms have struck out in many directions to reduce this cost to a minimum, and to this end the forms in most instances are designed in the

drawing office, and this, it is reported, at a cost of 2 per cent. and a saving of 10 per cent.

In his paper Mr. Graham then dealt with the kinds of timber that are used for formwork, the desirability of giving a camber to the bottom of beam boxes, the desirability of carefully checking the measurements, to see that the concrete members are actually carried out as designed, the necessity of having joints close to prevent the mixture escaping, the remedying of cracks, the removal of forms, clamps and nails to hold the forms together, the repair and re-use of formwork, the number of sets required in order to get on fast enough with the work of building, the importance of carefully clearing forms of all sawdust, dirt and chips before filling with concrete, the wetting of timber to prevent sticking, the use of sheet metal, the time for striking forms and methods of determining the strength.

ELECTRIC RAILWAYS IN GREAT BRITAIN

In a report of the railway department of the Board of Trade it is shown that since 1878 the mileage of the tramways in Great Britain has increased from 269 miles to 2,662 miles, while the capital expenditures have grown from $20,447,721 to $385,688,425.

The number of passengers carried in 1878 was 146,000,000 and for the year ended June 30, 1913, 3,220,000,000 or about 71 times the entire population. Net receipts of the tramways in 1878 were $1,122,490, and in 1913, $27,158,268. Of the mileage 1,818 miles are operated by municipalities. Of the total mileage 2,637 are operated by electricity.

Of the 286 tramway enterprises 171 are municipal and 115 are owned by private parties. Included are 13 miles of trackless trolley, which as yet show a deficit in operation. The net receipts of the municipal tramways for the year were $19,905,445 and of this $6,314,840 were applied to reduction of tramway debts, $2,646,163 to reduction in tax rates and $3,629,200 were carried to surplus. In four municipal tramway enterprises cost of operation exceeded gross receipts and in 25 municipal enterprises it was necessary to raise additional revenue from taxes to meet some part of the charges for the year. The total amount thus raised was $315,840 in 1913, as compared with $301,960 in the preceding year, which seems to indicate that the deficits are growing.

The average receipts per passenger in 1913 was 2.13 cents, as compared with 2.158c. in 1912, 2.46c. in 1898, and 3.68c. in 1878. As practically all English tramways use a zone system of fares it is difficult to give a comparison between the rate of fare in English cities with those in this country, where generally a single fare is charged for a ride of any length.

FOURTH AMERICAN ROAD CONGRESS.

Mr. J. E. Pennybacker, secretary of the American Road Congress has announced that the Fourth American Road Congress will be held in Atlanta, Ga., during the week of November 9th, 1914.

At a meeting held in London, England, on March 12, the reconstruction of the Newfoundland Oil Fields Company, Limited, was approved. The proposal is for a new syndicate with Sir Henry Blake as president, and with a capital of $24,000.

MAXIMUM FLOOD DISCHARGES.*

It is sometimes important to obtain the maximum discharge or maximum gauge height which a given stream is liable to have. This has assumed increased importance lately because of the disastrous floods of the past year. Even in parts of the country where very serious floods have not yet occurred people have begun to realize that they may have such a visitation. Some rivers, like the Mississippi, because of their extreme importance, have been the object of special study, and there is much information on hand concerning them; but for many streams the engineer is at a loss how to estimate for the highest future flood. The common method is to take the greatest gauge height on record and assume that there are to be none higher in the future, a method which leads to bad results unless the records include an extraordinary flood, which they may not do, even if they extend over a considerable period. It is also dangerous if the unusual flood occurred some time since and conditions in the valley have changed in such a way as to cause higher water for the same discharge per second.

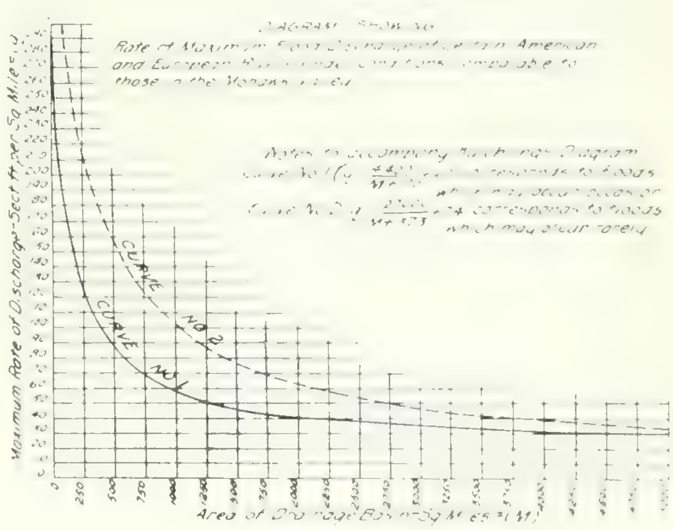

Fig. 1.

Another method of getting the maximum discharge is to look in encyclopedias, hand-books, text-books, etc., for information, and one is there met with all kinds of methods for getting the discharge. Some books will give the discharge in cubic feet per second per square mile for various kinds of country, from flat to very mountainous; some of them give the discharge as a function of the area, followed by a note saying that this formula applies to Northern India or Southern Italy, or some other place which the engineer is not interested in; and some books give the run-off from various classes of soil in terms of the rainfall. Then the engineer is as much at sea as ever, because the study of the rainfall is a complete problem in itself, and the flood may come from melting ice and snow or an ice gorge. The different results from the encyclopedia method do not seem to agree and the general result is more uncertainty.

Two studies on this subject have been made in recent years which seem to possess unusual merit. In connection with his report on the New York State Canal Survey, Mr. Emil Kuichling, M. Am. Soc. C.E., made an excellent study of flood flow on American and European streams. He obtained two equations which, with their

* From "Professional Memoirs" of the Engineer School, Washington Barracks, D.C., Vol. VI., No. 26.

corresponding curves, are shown on Fig. 1. It will be observed that the maximum rate of discharge is given per square mile in terms of the area of the basin in square miles, and small areas have a much larger unit flow. Curve No. 1 corresponds to floods which may occur occasionally, while curve No. 2 corresponds to floods which may occur rarely. The discharges indicated by curve No. 2 are larger than given by some authorities and much larger than are provided for in many places in this country. The reason of the latter is sometimes because people have not had that rare flood which may reach them any day, and against which many of them refuse to prepare until it has already occurred. The history of so many flood protection works is the story of a series of works with increased protection, the increased protection being added each time that a flood occurs larger than was expected. During the large flood which occurred in March, 1913, in the upper Scioto and Olentangy rivers, the discharge in each of these rivers at Columbus, Ohio, was, roughly, half way between the values given by the two curves. The Olentangy flows into the Scioto at Columbus. The discharge for the combined rivers is above the higher curve, or 90 second-feet per square mile with an area of 1,570 square miles, while Mr. Kuichling's curve No. 2 gives about 75 cubic second-feet for this area. (See report to City of Columbus on Flood Protection, by Alvord and Burdick, Hydraulic and Sanitary Engineers.) This would indicate that curve No. 2 is conservative. The flood at Columbus, while unprecedented for the Scioto River, would have been exceeded had the rainfall during March been moved only a short distance south or had there been snow on the ground. As it actually occurred, the belt of heaviest rainfall, instead of covering the Scioto Valley, covered only its upper portion, part of the belt extending across the watershed into the St. Lawrence basin.

Another excellent study which has been made recently was presented by Mr. Weston E. Fuller, M. Am. Soc. C.E., before the American Society of Civil Engineers and published in their Proceedings for May, 1913. Mr. Fuller's is a long and excellent article, and he presents a large number of tables with data from nearly all parts of the country, which are of great value in looking up the discharges that may occur in any particular section. Mr. Fuller does not compare floods by getting the maximum discharge, but compares the average flow for the day of maximum discharge, a method which has also been used by the United States Geological Survey. This average flow is obtained by dividing the total discharge in twenty-four hours by the number of seconds in a day. It will here be called the twenty-four hour flow, in counter-distinction to the momentary flow. Mr. Fuller compares the maximum twenty-four hour flow with maximum momentary flows, and also with what may be called average yearly flood flows.

Let Q (ave.) = average yearly flood flow obtained by getting the highest twenty-four hour flow for each year for a number of consecutive years and taking the mean expressed in second-feet.

Q = greatest twenty-four hour flow during a period of T years in second-feet.

Q (max.) = maximum momentary flow in second-feet.

T = the number of years in the period considered.

A = catchment area of the river in square miles.

For obtaining the relation between the flood to be expected in a series of years and the average yearly flood, he deduces the equation $Q = Q\ (\text{ave.})\ (1 + 0.8 \log. T)$, from which he computes the following table:—

Table I.

Time in years.	Ratio of largest flood to average yearly flood.
1	1.00
5	1.56
10	1.80
25	2.12
50	2.36
100	2.60
500	3.16
1000	3.40

Mr. Fuller further, for getting the relation between the maximum momentary flow and the maximum twenty-four hour flow in the same flood, deduces the equation $Q\ (\text{max.}) = Q\ (1 + 2A^{-0.3})$, from which he computes the following table:—

Table II.

Catchment area in square miles.	Ratio of maximum flood to average 24-hour flood.
0.1	5.0
1.0	3.0
5.0	2.23
10.0	2.0
50.0	1.62
100.0	1.5
500.0	1.31
1000.0	1.25
5000.0	1.15
10000.0	1.12
50000.0	1.08
100000.0	1.06

Frequently, gauge readings are available for a number of years, and if discharge observations are available a rating curve may be made, giving the relation between the discharge and the gauge height. Rating curves for many points have been made by the Geological Survey. With the gauge heights and the rating curve the value of Q (ave.) or the average yearly flood-flow may be determined, and by use of Table I. the largest flood against which it is desired to protect can be determined. The flood which occurs once in a thousand years will frequently be the proper one to protect against, as the thousand-year flood may be near at hand. With the greatest twenty-four hour flood so obtained you may proceed to Table II. and get the maximum momentary discharge, and by going to the rating curve translate this back into gauge heights if such is desired. Of course, one of the troubles with this method of Mr. Fuller's is in finding the value of Q, the average yearly flood-flow, as it is liable to be out badly unless the records for a long period of years are at hand; but, in any event, it is believed to be an excellent method of checking up results obtained by some other method, say, by Mr. Kuichling's curves. It has the great advantage of including all the peculiarities of the catchment basin, including rainfall and melting snow and ice characteristics. It is also of value where there are no discharge observations or rating curve, but otherwise sufficient gauge records available. This is probably a very common case. The discharge for each gauge height may be computed by use of Kutter's formulæ for the velocity $V = C\sqrt{RS}$ combined with the area of the cross-section. The area of the cross-section, the hydraulic mean depth, R, and slope, S, can be measured without waiting for a flood and by assuming *n* the coefficient of roughness, the value of C may be obtained from Trautwine's handbook or elsewhere. The rating curve may then be constructed, which is liable to be much in error

due principally to the value of n assumed, and by using Mr. Fuller's methods this error tends to come out "in the wash" by the time the results are translated back into gauge heights. Frequently it is the gauge heights rather than the actual discharge observations that are desired.

In their report, referred to above, Messrs. Alvord and Burdick used gauge records for sixteen years to find Q (ave.), the average yearly flood-flow for the upper Scioto, the Olentangy and the lower Scioto. Comparing these with the two highest floods on record the following ratios of Q (ave.) to Q are obtained:—

Table III.

	1913 Flood.	1898 Flood.
Upper Scioto	3.52	2.23
Olentangy	3.52	2.20
Lower Scioto	3.52	2.22

The value 3.52 is slightly greater than the ratio, 3.40, Mr. Fuller gets in Table I. for 1,000 years. 2.20 is between his ratios for 25 and 50 years.

Mr. Kuichling's studies naturally fall down when applied to some stream like the St. Joseph emptying into the Maumee at Fort Wayne, Indiana. This stream has a porous soil, and its maximum flood is only a fraction of that of the St. Marys River, the other tributary of the Maumee at Fort Wayne, although the St. Joseph has one-half larger drainage area. In such a case the methods of Mr. Fuller would naturally apply. But if there is nothing unusual in the basin of the St. Marys it would be safe to say it might have Mr. Kuichling's curve 2 discharge some day. The Scioto River, near at hand with its flood discharge, would indicate this.

Mr. Fuller's and Mr. Kuichling's studies seem to lend themselves to rivers the size of many of our navigable ones as well as small streams. In some cases other formulas or methods involving time and money for investigation give more accurate results, but the methods here presented give prompt results and often very valuable assistance. These methods, however, do not provide any factor of safety, they only give the maximum load. The levee or the bridge must be built a certain number of feet above the crest of the flood to provide this. It is desired only to call attention here to the factor of safety; it is too complicated a problem to be discussed in a few lines. It may be the best business risk to provide only against the ordinary flood without any factor of safety added. The land power-houses at the Ohio River Locks are being built with the idea that occasional floods will drown out the machinery.

PRELIMINARY STATEMENT OF MINERAL PRODUCTION OF QUEBEC, 1913.

The value of the products of the mineral industry of the province of Quebec in 1913 totalled $12,918,109. These figures are compiled from returns received by the Quebec Mines Branch direct from the producers. Although they are liable to change slightly, owing to additional dilatory returns, they are sufficiently near to give an accurate idea of the condition of the mining industry of the province. Annual mineral production since 1904 is shown by the following table:—

Year.	Value.
1904	[illegible]
1905	[illegible]
1906	[illegible]
1907	[illegible]
1908	[illegible]
1909	[illegible]
1910	[illegible]
1911	[illegible]
1912	[illegible]
1913	[illegible]

COST OF LOCATION SURVEY FOR A SHORT RAILWAY LINE.

ENGINEERING AND CONTRACTING, of Chicago, recently published some cost data that will be found interesting and of value, compiled from accurate records made in relation to some location surveys run in 1912 for a railroad. The survey was for a branch 30.75 miles long, from an already established line to a manufacturing city; with a branch survey, to another city, 12 miles in length. Topographical considerations, aside from large bodies of water and high hills, were found to be of minor importance, the chief concern being so to approach the intersected streets that grade crossings might be cheeply avoided. Most of the distance was through a light growth of timber, requiring much chopping and trimming. No topography was taken, but all streets and water courses along the line were carefully surveyed and the boundaries of private lands were run out.

For three weeks the men were boarded in hotels in the two terminal cities; during nine weeks they were carried by team or railroad to the work from headquarters on the main line; and for twenty weeks and two days they lived in camp. From the camp, which occupied three different sites, about 26 miles of location were made, teams being kept with the camp for transportation.

Table I.—Distribution of Labor.

Description of work.	Cost.	Cost per mile.	Pct. of labor total.	Pct. of grand total.
Running the line finally adopted	$1,500	$35.10	39.7	20.8
Running lines afterwards abandoned	432	10.10	11.4	6.0
Surveys of intersected streets	666	15.60	17.6	9.3
Leveling on line finally adopted	156	3.65	4.1	2.2
Leveling on lines afterwards abandoned	65	1.52	1.7	0.9
Leveling on intersected streets	20	0.47	0.5	0.3
Meandering ponds and streams	57	1.33	1.5	0.8
Surveying private boundaries	382	8.95	10.0	5.3
Triangulation and traverse lines	146	3.42	3.9	2.0
Exploration	10	0.23	0.3	0.15
Check levels	10	0.23	0.3	0.15
Office work by field men..	61	1.43	1.6	0.8
Holidays, absences and rainy days	270	6.55	7.4	3.8
Totals	$3,784	$88.58	100.0	52.50

Table I. of labor distribution does not include any general officers' salaries nor that of the chief engineer. The map drawing was done in the general office and does not figure in these tabulations.

Surveying instruments were supplied from those previously in use by the company, and interest on their cost is charged under "Field and Office Equipment." The camp equipment, consisting of seven tents, complete mess outfit, cot beds, blankets and quilts, was purchased second-hand at a discount of 50 per cent.

During the nine weeks above mentioned many days were lost on account of rain for which the men, being at home, were not paid. The pay of the party was as follows:-

Position—	Pay per day.
Assistant engineer in charge	$ 4.50
Transitman	3.33
Leveler	2.50
Axman and teamster, 7 days per week	2.25
Chainmen	2.00
Rodman	1.75
Axemen	1.50
Cook, per week	15.00

The total cost per mile given, $168.08 (Table II.) is the cost per mile of final location, and will be seen to include the cost of preliminary lines, and all the detail surveying necessary for complete land plans.

Table II.—Distribution of Expenses.

	Cost.	Cost per mile.	Pct. of exp. total.	Pct. of grand total.
Field and office equipment	$ 160.49	$ 3.75	4.7	2.2
Railroad and street car fares and expenses	453.73	10.60	13.3	6.4
Board and lodging	167.00	3.90	4.9	2.3
Team transportation	836.32	19.50	24.6	11.6
Camp equipment	209.16	4.90	6.2	2.9
Camp maintenance	1,488.92	34.82	43.9	20.7
Purchased information	81.38	1.90	2.4	1.4
Mail, telegraph and telephone	5.56	0.13	...	...
Totals	$3,402.56	$79.50	100.0	47.50
Grand totals	$7,186.56	$168.08	.....	100.00

Table III.—Analysis of Camp Maintenance.

Commodity.	Cost.	Cost per meal—4,047 meals.	Cost per man per day.	Pct. of total cost.
Meat, fresh and canned	$ 373.72	$0.092	$0.239	25.1
Fish, fresh and canned	51.93	0.013	0.033	3.5
Potatoes	29.84	0.007	0.019	2.0
Other vegetables	53.93	0.013	0.034	3.6
Fruit, fresh and canned	120.58	0.030	0.077	8.1
Groceries	108.56	0.027	0.069	7.3
Flour	31.92	0.008	0.020	2.1
Eggs	59.39	0.015	0.038	4.0
Sugar	27.49	0.007	0.018	1.9
Coffee	26.50	0.006	0.017	1.8
Tea	9.06	0.002	0.006	0.6
Butter	37.27	0.009	0.024	2.5
Milk	73.03	0.018	0.047	4.9
Ice	18.61	0.005	0.012	1.3
Fuel	36.23	0.009	0.023	2.4
Light	6.50	0.002	0.004	0.4
Water—6 weeks from city main	5.00	0.001	0.003	0.3
Land rentals	10.00	0.002	0.006	0.7
Cook's wages	305.34	0.076	0.196	20.5
Labor moving camp	104.02	0.026	0.067	7.0
Totals	$1,488.92	$0.368	$0.952	100.0

A study of the tables does not suggest much resemblance to similar ones previously published, the most marked difference appearing in the matter of camp maintenance, Table II. Much of the higher cost shown here is doubtless due to the high cost of living now prevailing. Also much may be due to the fact that all the men were accustomed to a pretty good table and an effort was made to provide them with home comforts.

SOME POINTS IN LAND SURVEY WORK.

By J. A. Macdonald, Ottawa, Ont.

IN surveying a field for the purpose of finding its area, the instruments and methods will be determined largely by the degree of accuracy required. If it is permissible to have an error of 0.5% the compass and chain are most conveniently used. If greater accuracy than this is required it will be necessary to use the transit and the steel tape. At the present time, however, in nearly all work except surveys of farms and woodlands, the transit is used even under conditions where the compass would give sufficient accuracy. In surveying a field, for example, all the angles and lengths of the sides are determined consecutively, the survey ending at the point from which it was started. By trigonometry the position of the final point, as of any other point with relation to the starting point, can be readily calculated. If the survey were absolutely correct the last point as calculated would coincide with the first, but this condition is never attained in practice. The calculated distance between the two, divided by the perimeter of the field is called the "error of closure." The term more properly applies to the actual distance by which the survey fails to close, and even when it actually closes in the field, it will not close in the plot. In surveying with a compass and chain the error of closure expected is about 1 part in 500.

In his own experience in land surveying, with both a transit and compass available, the writer has found little use for the transit in what is known as "custom work." Even when using the transit the magnetic needle on the transit must determine the meridian, and as all the surveying that had been done in Canada and elsewhere up to a few years ago was done by magnetic bearings, all work on old lines, such as retracing, re-surveys, subdivisions, etc., must necessarily be referred to the magnetic meridian; hence the absolute need of the compass.

If the transit is used in re-survey work in our old and settled provinces, it is of the greatest importance that the magnetic needle is of good length, and in good working condition, because one must ascertain his bearings by the needle. Even if he took the trouble to take an astronomical observation for azimuth the result would be of practically no value to the surveyor on such old work as retracements, re-surveys, etc. It is the writer's opinion that on the whole, for the surveyor who is doing "old work," a good compass will be found of more advantage than a transit. But if a transit can be obtained containing a reliable compass, with needle not less than 4½ inches long, there are added advantages in having a transit, though it is so much more cumbersome to carry about. As already stated, it all depends upon the nature of the work, but if errors are permissible of, say, 0.5%, or if much old work is to be done in the rural districts, then the compass is to be preferred. If the opposite condition prevails, and if much of the work is to be done in

towns and cities, then the transit must in all cases be used. The land surveyor should, however, possess both the compass and transit if the nature of his work varies.

Surveying for Area.—In making a survey it is customary to begin at some convenient corner and to take the bearings and the distances in order around the field. As the measurements are made they are recorded in a field book. It is not always necessary to take the sides in order, but since they must be arranged in order for the purpose of computing the area it will be convenient to have them so arranged in the original notes. It is of the utmost importance in every survey that check measurements be taken. Even a few rough checks taken in the field, which will require only a little extra time, often prove to be of great value in detecting mistakes. Both a forward and a back, reversed, bearing should be taken at each corner. From them the angles at a corner can be obtained free from error due to any local attraction of the needle. With the compass it is often impossible to set the instrument up at the corners of the property, and in such cases assumed lines running parallel, or approximately so, to the property lines can be surveyed and the area determined. In some cases the instrument can be set on the property line at an intermediate point and the bearing obtained; but the surveyor must be sure that there is no local attraction of the needle at this point. All points where a compass-instrument is set should be marked and described so that they can be found again. If any instrument point is not otherwise defined it may be temporarily marked by a small stake and several reference measurements made from this stake to prominent objects nearby, so that the position can be determined if the stake is lost.

Division of a Property.—In order to divide a piece of land into two equal parts, the first thing the surveyor would do in most cases is to measure the width of the field on a course perpendicular to the sides. But in the case illustrated in Fig. 1 a river intervened, running in the direction of such a line and with its banks covered with a dense growth of alder and marsh, an almost impossible condition through which to cut a line. Another creek, with steep banks intervened further on, and the remainder of the area was covered with a dense growth of forest trees. By extending the outlines at (o) and (3) across the road and into the property to the east, a solution of the difficulty would seem apparent, but, to extend or prolong the line at (o) involved difficult cutting out of a line, while to the north of the river, and east of the road, was private property, most of which was under tillage, etc.

A simple method of overcoming these difficulties was devised by traversing the road from the post at (o) to the opposite side of the area at (3) and when completed calculating the latitudes. At Station (o) the instrument was set up and an angle or bearing of 18°00 (N.18°00'.E) turned, and the line measured to (1), 9.00 chains. At (1), the bearing was N.14°15'.W, and the line to (2), 3.10 chains. At (2), the angle was 35°00', (N., 35°00', W) to (3). These courses, with their latitudes and departures, dotted, are shown in Fig. 1.

One might be inclined to think that to divide a piece of land with parallel sides would be an extremely simple matter. Were the property abutting upon a straight road at right angles to the side lines no doubt the finding of the centre would only be a matter of measurement; but running in a semi-circular form, as the road does in Fig. 1, renders the problem somewhat difficult, since to go to the labor of opening a line through the wood, at right angles to the sides, could not be done without an instrument.

Table I.—Traverse.

Station.	Bearings.	Distance.	Latitude.	Departure.	Total latitude.
(o)	18°00	9.00	8.56	2.75	....
(1)	14°15'	3.10	3.00	.75	8.56
(2)	35°00'	3.20	2.62	1.83	11.56
(3)	....	...	...	...	14.18

The total width of the lot to be equally divided is therefore 14.18 chains, and the centre will be 7.09 chains from either side to make an equitable division. We now undertake to find the point 7.09 chains from Sta. 3. This will be a simple matter as we already know the distance from (3) to (2), and from (2) to (1) or 5.62 chains. The centre will then be 1.47 chains in latitude from Sta. (1) (7.09 — 562 = 1.47). Knowing the latitude and the angle from (1) to (o) (which is the same as the angle at

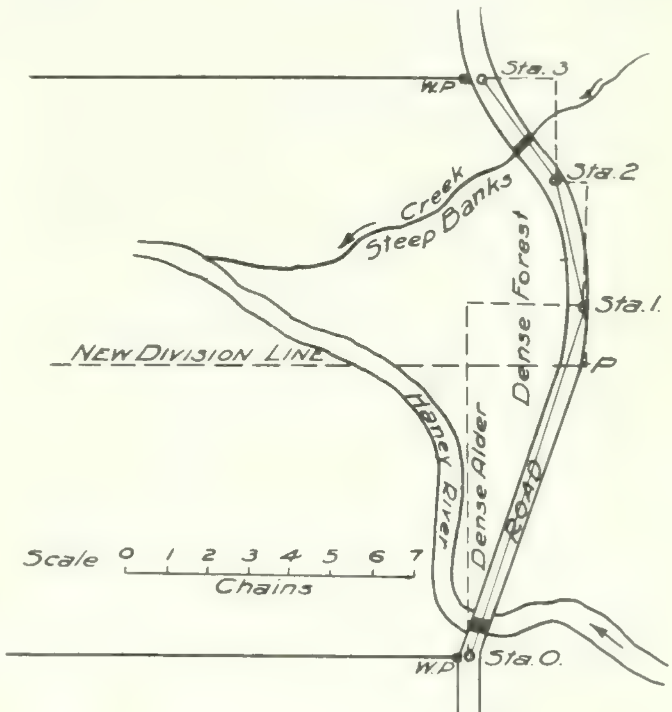

Fig. 1.

(o), viz., 18°00), divide the latitude, 1.47, by the natural cosine of 18°00' to obtain the distance to the point, P, the centre. This is found to be 1.54. By measuring back on the road line 1.54 chains, we are at the precise centre, 7.09 chains. At this point, P, we set up and run the division line east, parallel to the side lines, or outlines of the lot. Thus, by a little ingenuity and trigonometry the precise division of the contained area was obtained without having to cut out a line or trespass on the adjoining private property.

Note Keeping.—All measurements should be recorded in a special note book as soon as they are made and not left to be filled in from memory. The notes should be neat and clear, so that there will be no doubt as to their meaning. Great care should be taken so that they will not be susceptible to any interpretation except the right one. They are generally recorded in pencil, but they should always be regarded as permanent records and not as temporary memoranda. As other persons who are not familiar with the locality will probably use the notes and will depend entirely on what is recorded,

it is very important that the notes should contain all necessary data without any superfluous information. If the notekeeper will bear in mind constantly how the survey is to be calculated or plotted it will aid him greatly in judging what measurements should be taken and what are unnecessary. Clearness is of the utmost importance in note keeping, and to attain it the usual custom is not to attempt to sketch to scale. Yet, in surveys where considerable detail is desired, it is sometimes well to carry out the sketches in the note book approximately to scale. Care should be taken not to crowd the notes—paper is cheap—and an extra page of the note book devoted to a survey may save hours of time consumed in the office in trying to interpret a page of crowded data.

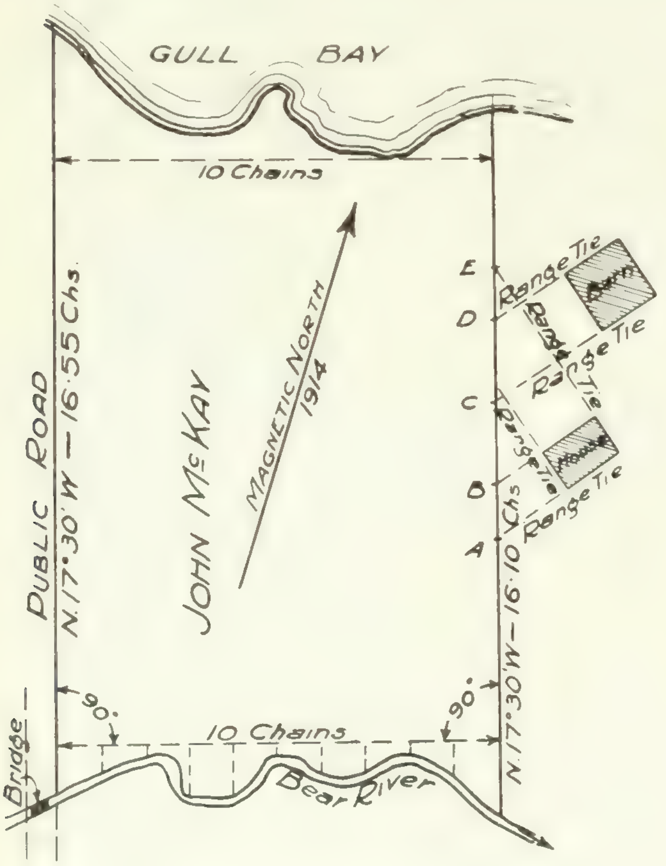

Fig. 2.

Where the work is of an intricate nature, the sketch should show roughly with pencil the various triangulations, etc., as in Fig. 1. This will greatly aid in the plotting.

Too much stress cannot be laid on the importance of being careful not to lose the note book, as not infrequently a note book contains data which thousands of dollars could not replace.

Although sufficient fullness to make the notes clear is desirable, it is customary to abbreviate the names of the features most commonly met with by the surveyor. To properly understand a set of notes one must be familiar with these abbreviations, as W.P., wooden post; I.P., iron post; I.P.M., iron post and mound; I.P.Pits, iron post and pits; Wit.I.P. or Wit.I.P.M., witness iron post—a monument placed some distance from the precise spot or true corner where a monument should be, but, owing to obstructions, cannot be made there; Temp. P., temporary post; etc. Distances should always be recorded in the note book in such a way as to indicate the precision with which they are taken. For example, if they were taken to 1/100 ft. and a measurement happened to be just 124 ft., it should be recorded 124.00. The two zeros are of as much consequence as any other two digits which might have come in their places. In addition to the measurements, every set of notes should contain the following information: Kind of work, locality, date, names of members of the field party, instruments used, etc. Where a survey is continued for several pages, the date may be placed at the top of every page, but the the other data need not be repeated.

Survey for a Deed.—In this case the lengths and bearings of all the boundaries are desired. The traverse lines should therefore follow the property lines, if possible. In case a true meridian is found by observation or by calculation, the bearings should be referred to this and marked "true bearings" by a note on the plan. This information should also be contained on the deed. More frequently, however, it is the magnetic bearing that is given. A plan which is to accompany a deed should show such features as watercourses, highways, buildings, and adjoining property lines, as well as stone mounds, stakes, fences, walls, or other artificial objects which mark the boundaries of the property. This plan should contain the following information:—

Lengths of all property lines together with their calculated bearings, or the angles at the corners; location and description of corner bounds; conventional sign or name on fences, walls, etc.; names of highways, streams or ponds, and of adjacent property owners; scale of drawing and direction of the meridian used. (It is better to refer all bearings to the true meridian when this is possible, and in such a case the direction of the magnetic needle should be shown in addition.)

The title should include a simple and complete statement giving the name of the owner, place, date and name of surveyor.

The written description of the property which is recorded in the deed should be given by bearings, or angles, and distances, stating in every case how the sides of the property are marked and whether bounded by a highway, stream or private property, giving the name of the present owner of the adjacent property.

It is customary with many surveyors to omit from the plan certain of the above enumerated data, so that while it may answer the purpose for which the survey was made, it does not contain all the data, and frequently not enough to enable another surveyor to relocate the property by means of it. This is done, of course, so that when the tract is to be re-surveyed, plotted, transferred or conveyed by deed to another party, it will be necessary to employ the same surveyor who has in his possession data for which the owner presumably has paid, and which the surveyor should have turned over to him on the completion of the survey. The plan and description of the survey should be so plain that any other surveyor could instantly interpret it, or that a lawyer could draw up the conveyance or transfer directly from the descriptive plot without confusion.

Judicial Functions of the Surveyor.—In running old and obliterated property lines, the surveyor is called upon to set aside temporarily his strict adherence to the mathematical side of surveying, and must endeavor to find, if possible, where the lines originally ran. He should, therefore, be familiar with the relative importance of evidence regarding the location of the property lines. It is his duty to find the position of the original boundaries of the property, and not attempt to correct the

original survey, even though he may be sure that an error exists in it. This is the concensus of opinion among surveyors, and also of the courts, and should never be lost sight of. Very often it is true that, owing to the cheapness of land, the original survey was roughly made, with little thought of the effect it would have when the land became valuable.

The surveyor, therefore, must first of all acquire all physical evidence of the location of the boundaries. Failing in this, he will use his best judgment on any and all other reliable evidence, such as occupancy or possession or the word of competent witnesses. It must not be assumed that boundaries are missing because they are not at once visible. Stone mounds are often buried two or three feet deep, while the top of a stake soon rots off; but evidences of the existence of the stake are often found many years after the top has disappeared. The supposed location should be carefully dug over to find traces of the old stake.

A dispute between adjoining owners over the location of a boundary line presents a question which must be settled by the courts unless the parties can come to an agreement. In such cases the surveyor has to act simply as an expert judge as to where the line originally ran, and he has no power to establish a new line. He can, however, be employed as an arbitrator to decide on the equitable line, but they are not necessarily obliged to accept his judgment. If they come to an agreement, however, between themselves in the presence and with the concurrence of the surveyor, regarding the location of the line, and occupy to that line, this agreement is binding, even though no court has intervened in the matter.

It is to be assumed that the deed has been drawn by the grantor with honest intent to convey the property to the grantee. It is intended, then, that it shall be interpreted, if possible, so as to make it effectual. The deed should also be construed in the light of what was known at the time when the title was transferred. In this interpretation it is assumed that it was intended to convey property, the boundaries of which will form a closed traverse. It is then within the jurisdiction of the surveyor to reject any evident mistake in the description when running out the property line. Where artificial features are mentioned as boundaries, these always take precedence over the recorded measurements or angles, but these marks must be mentioned in the deed in order to have the force or authority of monuments. When the area does not agree with the boundaries as described in the deed, the boundaries control. All distances, unless otherwise specified, are to be taken as straight lines, but distances given as so many chains or feet along a highway or street are supposed to follow these lines, even if they are not straight. When a deed refers to a plan the dimensions on this plan become a part of the description of the property. When property is bounded by a highway, the abutters usually own to the centre line, but where it is an accepted street each abutter yields his portion of the street for public use, but if it happens that the street is abandoned the land reverts to the original owners. If a street has been opened and used for a long period, bounded by fences or walls, and there has been no protest regarding them, these lines hold as legal boundaries. In the case of a line between private owners acquiescence in the location of the boundary will usually make it the legal line. But if there is a mistake in its location and the question of its position has not been raised, occupancy for many years does not make it a legal line, though the rule or "law" of "21 years peaceable possession" make a strong legal claim. Where property is bounded by a non-navigable stream, as south boundary of Fig. 2, it extends to the thread of the stream., i.e., the centre of the channel. If the property is described as running to the bank of a river it is interpreted to mean to low-water mark, unless otherwise specifically stated. Where the ownership originally ran to the shore line of a navigable river and the water has since receded, each owner is entitled to his proportional share of the channel of the river.

Irregularly Curved Boundaries.—When a tract of land is bounded by an irregular curved line, such as a brook, as in Fig. 2, it is customary to run the traverse line near it, and may be sometimes crossing it several times, and to take perpendicular offsets to the brook. (These offsets are shown in Fig. 2.) If it is a winding brook with no distinct turns in it, offsets at regular intervals are measured from the transit line, as in the portion of the south boundary, Fig. 2. Since they are usually short, the right-angled offset lines are frequently laid off by the eye, or simply paced.

PERSONALS.

S. P. BENNETT has been appointed Municipal Engineer of South Vancouver municipality.

JAMES WOODRUFF has been appointed Road Commissioner for the township of Niagara.

R. PIERCEY has been appointed chief assistant and C. K. SAUNDERS assistant to W. J. Johnson, Engineer of Saanich Municipality, British Columbia.

PHELPS JOHNSON, president of the St. Lawrence and Dominion Bridge Companies and past president of the Canadian Society of Civil Engineers, is on a trip through Western Canada.

S. B. WASS, assistant chief engineer, St. John Quebec Railway, is chief engineer of the Quebec Extension Railroad, a proposed line 174 miles in length in Quebec and the State of Maine.

C. A. P. TURNER, consulting and contracting engineer, Minneapolis, advises us of the removal of his office in that city from the Phenix Building to the new Walker-Burton Building.

F. A. GABY, chief engineer of the Hydro-Electric Power Commission of Ontario, addressed the members of the Canadian Institute on March 21st. Mr. Gaby's lecture was a general treatment of the development and use of hydro-electric power.

VINCENT SIMPSON, secretary-treasurer of Gerald Lomer, Limited, Montreal, is making an extended business trip through the West in the interests of the Phœnix Steel Pipe Works, of Dusseldorf, and Deutsche Maschinenfabrik, A.G., of Duisburg, Germany.

R. F. HAYWARD, general manager of the Western Canada Power Company, addressed a recent meeting of the Manufacturers' Association of British Columbia on the subject of power. He outlined the increasing advantages and the utilitarian value of electrical power in a wide range of industries.

Several years ago, a scheme was advocated to construct a bridge across the gorge at Niagara Falls, N.Y., below the falls and close to the foot of Niagara Street. This project is being revived

Coast to Coast

Edmonton, Alta.—The deficit of the Edmonton Street Railway department for 1913, which amounted to $190,000, has brought the actual deficit of that department, after six years' operation, to almost $400,000.

Toronto, Ont.—The Ontario Legislature has favored urging upon the Federal Government the importance of granting a measure that will stimulate anew the iron industry of Canada, the form of assistance to be left to the discretion of the Federal Ministers.

Montreal, Que.—Improvements effected by the new Montreal Harbor Commission during its first year of office in 1913, necessitating an expenditure of $3,787,430 on capital account, and $1,325,6[illegible] on revenue account against which there were total revenue receipts of $1,361,964, are shown in the annual report of the commission recently issued.

Ottawa, Ont.—The powerful ice-breaker, for which the Ottawa Government has recently awarded a contract to the Canadian Vickers Company, will be of 8,000 h.p. The plan is to put the ice-breaker at work at the Cap Rouge [illegible] bridge, prevent the accumulation of ice and afterwards to work between there and Montreal along with the Lady Gray and Montcalm. Not only will the opening of navigation be greatly advanced, but the spring floods along the St. Lawrence obviated.

Fredericton, N.B.—The C.P.R. has prepared plans for considerable work on the Atlantic Division for the present season; and while the work to be done will not be so extensive as during the past few years, it will be sufficient to maintain the efficiency of the line. Thirteen miles of new 85-pound rails will be laid on the main line between St. John and Megantic. On the main line, also, 40 wooden and dry stone culverts will be replaced by concrete, as well as a number of culverts on the branch lines. Twenty-five miles of ballasting will be done on the main line; while on the branch lines 61½ miles of light rails will be replaced by heavier rails, and 55 miles of ballasting will be done. A new loading siding will be built at St. Stephen; at Cardigan, at Burnside and Zealand on the Gibson branch loading sidings will be extended; and at Somerset Junction, in Maine, a new freight shed and two additional sidings will be built.

Vancouver, B.C.—The P.G.E. Railway Company has decided to proceed this year with the work on the establishment of docks and terminals at Squamish, and has estimated the expenditure for 1914 at $200,000. The company's plans for the year call for the reclamation of the tide flats of at least a mile in area, and also for dredging a considerable portion of the harbor. Also, it has been stated by Mr. J. W. Stewart, president of the company, that the company expects to award contracts by May 1st for the construction of the portion of the Peace River route; and it is expected to cover 100 miles of the new line this summer and to have grading on the entire section of 330 miles north-east from Fort George under way in the summer of 1915. The extension is to be finished and ready for operation right through to the Alberta boundary in 1916. Grading will be rushed on a section 150 miles from Fort George to connect with the portion now under construction north of Clinton, and on the other contracts to be let this season.

Victoria, B.C.—Dredging operations of the site of the new Marine and Fisheries depot have reached such a stage that the successful tenderers will be able to proceed with the construction of the Government wharf immediately the contract has been awarded. For the past three months the dipper dredge Mudlark has been confining its operations closely to the deepening of the channel in the immediate vicinity of the proposed wharves, until, at the present time there is a uniform depth of 18 feet at low water on the north side of the proposed wharf, while great progress has been made in digging out the hard-pan parallel with the channel. Already on the north side, running inshore to the Songhess Reserve, the Mudlark has taken out 52,000 cubic yards of material, and the dredge is now engaged in dredging out 35,000 cubic yards from the foreshore, running north and south. Upon the completion of this work during the next month, a total of 87,000 cubic yards will have been removed. When completed, the new Government wharf will be 450 feet in length, running north and south on the channel side, and will run inshore 210 feet, giving a depth of from 18 to 20 feet of water at low tide

Victoria, B.C.—The Provincial Legislature has considered recently the estimates for the fiscal year, 1914-15. The estimated expenditure has been placed at $13,742,009.60, and the estimated revenue at $10,048,915.15. Among the votes affecting engineering projects at Victoria and in the immediate vicinity, are: $340,000 for Soughees Indian Reserve improvements; $315,000 for the extension and completion of the provincial parliament buildings; and $245,000 for the completion of the provincial Normal School. The total estimated expenditure on public works throughout the Province is $5,316,575. Of this amount $2,319,500 will be spent on works and buildings; $2,861,000 on roads, streets, bridges and wharves; $96,075 on subsidies to steamboats, ferries and bridges; and a balance of $40,000 on general contingencies. Other votes of important engineering interest coming under appropriations for other departments of the government are $500,000 for work upon the new provincial university; $150,000 for government buildings at Prince Rupert; a revote of $50,000 for the completion of the courthouse at Vernon; a conditional revote of $400,000 for the bridge across Second Narrows, Burrard Inlet; and a vote of $100,000 for development work at Strathcona Park. The appropriation for the Forestry branch showed an increase of $78,000; the Lands branch, a decrease of $124,000; the Surveyor-General's department, a decrease of $165,000; but the Water Rights branch, an increase of $67,000.

St. John, N.B.—The report of Mr. Monsarrat, chief engineer of the Quebec bridge construction, upon the most suitable site for a bridge on the St. John Valley Railway over the River St. John, stated that borings at Dunham's Wharf, one and a half miles above the Mistake, the point previously most favored, disclosed a deposit of sand 50 to 60 feet deep overlaying clay which would furnish a satisfactory formation for supporting piles upon which to build concrete or masonry piers. Towards the east shore he had located the 500-foot span which would provide for no interruption to logging operations, and on the west side near the deeper channel, a 25-foot swing span. He believed this to be the best of three projected sites. He would not recommend any earth or rock filling. He was satisfied a bridge could be constructed across the river at this location which would cost approximately $2,063,756, subdivided as follows:—superstructure, $543,715; substructure, $1,283,877; rock fill, $47,000; track and telegraph, $1,550; engineering and contingencies, $187,614. However, the Foundation Company, Limited, of Montreal, had been asked to make an examination and to give an estimate on the work. That company concurred in the desirability of the site recommended, and reported that it could build the substructure for the sum of $1,135,000, and have it completed by December 1st, 1915; and also could so arrange the construction of the piers that the steel work could be erected by December 31st, 1915.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page [illegible] a directory of such societies and their chief officials.

D.L.S. EXAMINATIONS.

The result of the examinations held in February by the Dominion Land Surveyors' Association were announced last week. Examinations were held in the principal cities of the Dominion, and the number of candidates were 199. From the following results it will be noted that out of this number 15 candidates passed their final examinations, 37 passed the full preliminary and 3, the limited preliminary test. The list is as follows:—

Final.—F. Alport, Orillia; H. C. Bingham, Regina; L. E. S. Bolton, Listowel; R. F. Clarke, Kingston; H. J. Ewan, Yarmouth, N.S.; J. F. Fredrette, Ottawa; A. M. Grant, Ottawa; J. A. S. King, Ottawa; R. A. Logan, Middle Musquodoboit, N.S.; C. S. MacDonald, Ottawa; P. J. McGarry, Toronto; W. H. Norrish, Ottawa; B. C. Pierce, Kingston; G P. Sharpe, Salmon Arm, B.C.; R. L. Squire, Ottawa; F. H. Wrong, Sandwich, Ont.

Full Preliminary.—C. H. Biddell, Regina; J. C. Bonham, Kingston; C. A. Buck, Edmonton; F. R. Burfield, Calgary; L. C. Calder, Bergen, Alberta; J. Carroll, Toronto; C. W. Cohoon, Ottawa; W. S. Cole, Kingston; C. W. Crowell, Yarmouth, N.S.; E. M. DesBrisay, Montreal; G. H. Donaldson, Ottawa; W. L. Frame, Montreal; J. T. Fullerton, Montreal; C. E. Joslyn, Kingston; K. Keeping, Montreal; G. L. Kezar, Britannia Heights, Ont.; A. M. Knight, Edmonton; C. A. R. Lawrence, Toronto; C. C. Lindsay, Montreal; J. E. Lyon, Ottawa; F. J. Martin, Winnipeg; A. H. Meitz, Toronto; T. S. Mills, Prince Albert; W. S. McDonald, Edmonton; M. D. McFarlane, Montreal; H. R. Mackenzie, Regina; H. A. Parker, Blairton, Ont.; J. M. Paul, Calgary; G. B. Patterson, Kingston; H. B. Pelletier, Montreal; C. E. Richer, Ottawa; J. Robertson, Lachine Locks, Que.; D. N. Sharpe, Winnipeg; G. J. Smith, Kingston; C. H. Tory, Edmonton; A. G. Wilkins, Ottawa; H. C. Wright, Roblin, Ont.

Limited Preliminary.—L. C. Prittle, Carleton Place, Ont.; J. H. Ramsay, Ottawa; G. A. Wall, Calgary.

CAN. SOC. C.E.—VANCOUVER.

The Vancouver branch of the Canadian Society of Civil Engineers had a meeting on March 18th, which was addressed by Mr. J. W. B. Blackman upon the subject of town planning. Mr. Blackman outlined the development of the idea of scientific planning of towns and cities since the days of Pompeii. His lecture was illustrated by lantern slides and the general trend of his treatment of the subject was the condemnation of the invasion of sky-scrapers into our cities.

CAN. SOC. C.E.—CALGARY.

On February 20th, the Calgary branch of the Canadian Society of Civil Engineers was addressed by F. H. Peters, C.E., Commissioner of Irrigation, the subject of his lecture being "The Georgian Bay Ship Canal." He summarized the advantages and disadvantages of the project now under investigation comparing its estimated value to Western Canada with that of the new Welland Ship Canal and the Hudson's Bay Railway. According to Mr. Peters, the basic principle underlying the advisability of constructing the Georgian Bay Canal was the cost of various kinds of transportation. He outlined the progress that was being made on the Welland Canal and on the Hudson's Bay Railway and explained the movement for the Georgian Bay Canal as being a third project in the interests of cheaper cost of transportation in shipping material in and out of Western Canada.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Diven, 47 State Street, Troy, N.Y.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9-13, 1914. J. E. Pennybacker, Secretary, Colorado Building, Washington, D.C.

AMERICAN PEAT SOCIETY.—Eighth Annual Meeting will be held in Duluth, Minn., on August 20, 21 and 22, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

AMERICAN SOCIETY FOR TESTING MATERIALS—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

OBITUARY.

We regret to record the death of Mr. FRANCIS S. CLEARY, a young engineer who died on March 24th at Monrovia, Cal. Mr. Cleary was born in Windsor, Ont., 27 years ago. He was educated at Windsor Collegiate Institute, St. Michael's College and Faculty of Applied Science and Engineering, University of Toronto, graduating with the class of 1911. During the past two years he has been employed as an electrical engineer with the Edison Illuminating Company of Detroit.

The death has been announced of F. D. FRIEND, resident engineer for the National Transcontinental Railway at Graham, Ont. Heart failure was the cause. Mr. Friend was a native of Devonshire, England and came to Canada about 10 years ago.

The death was announced on March 18th of DAVID-KEAY McLAREN, president of D. K. McLaren, Limited, Montreal. Deceased was [illegible] years of age.

B. W. FOLGER, president of the Kingston Street Railway, and well known in railway and steamship circles throughout Ontario, died in Toronto last week.

The Great Western Railway Company of England has just placed an order with Herbert Morris, Limited, for the supply of all chain blocks that they require during the year 1914. This is the 13th consecutive yearly repetition of the exclusive use of Morris chain blocks on the Great Western Railway.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21505—March 16—Approving revised location C.N.R. through Sec. 19-2-6, and Sec. 24-2-7, W. 2 M., Sask., mileage 0.00 to 1.43; and authorizing construction of revised line across road between Sec. 19-2-6, and Sec. 24-2-7, W. 2 M.

21506—March 16—Approving plans showing superstructure of eight (8) bridges on 13th Dist. of G.T.R., Province of Ontario.

21507—March 17—Directing that G.T.R., on or before June 15th, 1914, install gates at St. Clair Ave., Toronto, Ont., operates by day and night watchman; 20 per cent. of installing gates be paid by Ry. Grade Crossing Fund, remainder, 1-3 by city, and 2-3 by Ry. Company.

21508—March 14—Directing that G.T.P. Ry., at own expense, make certain changes in highway crossings in Tp. 34, Rgs. 1 and 2, W. 3 M., Sask.; work be completed by May 31st, 1914.

21509—March 16—Authorizing G.T.R. to construct siding into premises of the Chalmers Milling Co., west of Dawes Road, Toronto, Ont.

21510—March 16—Approving G.T.R. plan showing proposed arrangement for lighting vehicular and pedestrian roadways on Victoria Bridge, Montreal; work to be completed within 3 months from date of this Order.

21511—March 17—Authorizing C.N.R. to construct across and divert public road between N.E. ¼ Sec. 33-28-20, W. 3 M., and N.E. ¼ Sec. 4-29,20, W. 3 M., Sask., and divert highway between N.E. ¼ Sec. 33-28-20, W. 3 M., and N.W. ¼ Sec. 34-28-20, W. 3 M., to new crossing, in N.E. ¼ Sec. 33, at station 5684-20.2.

21512—March 17—Authorizing Cedars Rapids Manfg. and Power Co., Montreal, to take additional width of 25.9 ft. for right-of-way for transmission line, making in all a width of 125.9 ft. across Lot 338, Parish St. Joseph de Soulanges, County of Soulanges, Que., property of Archelas Clement.

21513—March 16—Authorizing London and Lake Erie Ry. to connect its tracks with Michigan Central R.R. Co., at west end of city of St. Thomas, Ontario.

21514—March 17—Authorizing G.T.R. to re-construct, subject to condition contained in consent on behalf of Tp. London, overhead bridge carrying highway, known as Westminster Road, between Lots 18 and 19, Con. 1, Tp. London, Co. Middlesex, Ont., over its railway, mileage 121.58 from Suspension Bridge.

21515—March 18—Approving Marconi Wireless Telegraph Co., of Canada's Tariff C.R.C. No. 8, covering new rates for cable letters and week-end letters; said tariff to be filed in form prescribed under Order No. 6679 (General Order No. 32), dated March 26th, 1909.

21516—March 17—Amending Order No. 21417, dated Feb. 27th, 1914, by striking out figures "18903.38" after word "File" wherever they occur in said Order and substituting therefor figures "18903.47"; and striking out figures "131" wherever they occur in said Order after work mileage and substituting therefor figures "161.1."

21517—March 16—Amending Order No. 17400 dated Aug. 30th, 1912, by striking out figures and words, "Lot 31, 0.14" in last line of operative part of Order and substituting therefor words and figures, "Lot 22, Concession 1, 0.72."

21518—March 18—Directing that, on or before April 1st, 1914, C.P.R. restore old clearance by raising under-side of top of culvert eleven inches (bridge over North Branch of the Clyde River, between mileages 24 and 25, just north of Flower Station, Ont.)

21519—March 19—Amending Order No. 21418, dated Feb. 14, 1914, by striking out figures "25" before word "August," where they occur in recital of Order, and substituting therefor figures "29," to read "29th August, 1913."

21520—March 16—Authorizing city of Montreal to construct 8 ft. diameter steel water pipe beneath tracks and across and along lands and right-of-way of G.T.R., upon Lot No. 3410 on Cadastral Plan of Mun. of Parish of Montreal, to be used as Emergency Supply in case of accident to regular water supply for city, subject to and upon certain conditions.

21521—March 19—Authorizing C.N.O.R. to construct trestle to carry its railway across Indian River, Tp. Fraser, Co. Renfrew, Ont., at mileage 101 from Ottawa.

21522—March 19—Directing that C.P.R. stop train No. 22 on flag, daily except Sunday, at St. Clet, Quebec.

21523—March 20—Authorizing C.P.R. to take certain lands situate in Lot 6, Con. 4, west of Hurontario St., Tp. Toronto, Co. Peel, Ont., for purpose of revising and enlarging its station yard at Streetsville Jct.

21524—February 26—Authorizing, subject to terms and conditions contained in agreement, dated June 14th, 1910, G.T.R. to construct siding into premises of Terminal Warehouse and Cartage Co., Limited, west of Common St., Montreal, Que.; and that the Order of Board No. 9859, dated March 9th, 1910, be rescinded.

General Order, No. 123—March 19—Approving form "Release of Responsibility," No. 981, respecting carriage of clothing, wearing apparel, and personal effects (all second-hand), in trunks, securely corded, submitted by C.N.R. That said Form of Release be made applicable to all railway companies under jurisdiction of the Board, until the Board orders otherwise.

21525—March 20—Authorizing G.T.R. to operate sixteen (16) bridges on its 30th District.

21526—March 20—Authorizing G.T.R. to operate trains over bridge carrying 16th District of its railway across Birch Ave., city of Hamilton, Ontario.

21527—March 23—Amending Order No. 19958 by inserting, after item No. 3, following words and figures: "No. 3a. 0.98, Pie LX Street, Railway to cross over highway by means of a bridge, having four openings instead of five, as shown on the said plan, dated 16th November, 1912." That Orders Nos. 16998, 17572, 19286, 19800, 19958, 21414, and this Order, be certified by Sec. of Board and endorsed as provided by Sec. 46 of Rly. Act., and transmitted to Prothonotary of Superior Court in and for Dist. of Montreal, Que.: Provided said Order be without prejudice to rights, if any, to city of Montreal.

21528—March 20—Authorizing C.N.O.R. to take portions of Lots 81 and 82, parish of Ste. Dorothee, Co. Laval, Que., property of Hormisdas Bibault and Onesime Lafontaine.

21529—March 21—Relieving C.P.R. from providing further protection at crossing of Government Road, west of station building at Mortlach, Sask.

21530—March 23—Authorizing G.T.R. to construct 2 bridges—namely, No. 138, mileage 91.90, 17th Dist., nearest Station Woodstock, Ont., and No. 7, mileage 6.15, 15th Dist., nearest station Weston, Ont.

21531—March 21—Authorizing C.P.R. to use and operate Bridge No. 2.65 on its Prescott Subdivision, Eastern Division.

21532—March 23—Amending Order No. 21508, dated March 14th, 1914, by adding following paragraph:—"And it is further ordered that after the completion of the work, the Railway Co., may close the old road allowances across its right of way; the road allowances according to the new survey to be substituted in lieu thereof."

21533—March 23—Approving proposed deviation of Essex Terminal Ry. Co.'s line, as already constructed, between a point near Bedford St., town of Sandwich, Ont., and Detroit River.

CONSTRUCTION OF THE NEW QUEBEC BRIDGE

EVENTS LEADING UP TO THE PRESENT UNDERTAKING—NOTES ON THE COMPLETED MASONRY—ERECTION DETAILS AND POINTS OF SPECIAL INTEREST IN THE SUPERSTRUCTURE.

At a meeting on February 25th, 1914, the Toronto branch of the Canadian Society of Civil Engineers was addressed by Mr. C. N. Monsarrat, Chairman and Chief Engineer, Board of Engineers, Quebec Bridge. On March 2nd, Mr. Monsarrat delivered a somewhat similar address before the Canadian Club of Montreal. His subject at each meeting was a description of the reconstruction of the new Quebec Bridge, and from his remarks the following synopsis is presented:

As early as 1852 a project for a bridge over the St. Lawrence River at Quebec was considered, and again in 1884 a design was prepared and submitted to the Quebec Board of Trade for a bridge at about the present site, but nothing actually was done until about 1900, when the Quebec Bridge and Railway Company located a site near Cap Rouge and took definite steps towards the erection of such a structure. This location is at the narrowest point on the St. Lawrence River between Montreal and Quebec, the width at mean water level being about 2,000 feet. The water at this point has a maximum depth of about 200 feet and a current at ebb tide of about 7 miles per hour. The Bridge and Railway Company awarded contracts in 1900 for a bridge of the cantilever type having a main span of 1,800 feet. Work was started and proceeded until the year 1907, when about half the superstructure, then erected, collapsed. Soon after this lamentable disaster the Dominion Government undertook to reconstruct the bridge, and in 1908 appointed a board of three engineers for that purpose. This board made very exhaustive studies of various designs, including suspension and cantilever bridges, and finally decided, for good and sufficient reasons, that the cantilever type of bridge was the most satisfactory and economical kind of structure for such a crossing. It also decided that the bridge should be much wider and designed for heavier loading than the former bridge, that the same length of main span should be retained and that it should be built at the same site. Several changes were made in the personnel of this Board during the progress of the work, and since the contracts were let the Board has been composed of Mr. Ralph Modjeski, Mr. C. C. Schneider and Mr. Monsarrat, who is chairman and chief engineer.

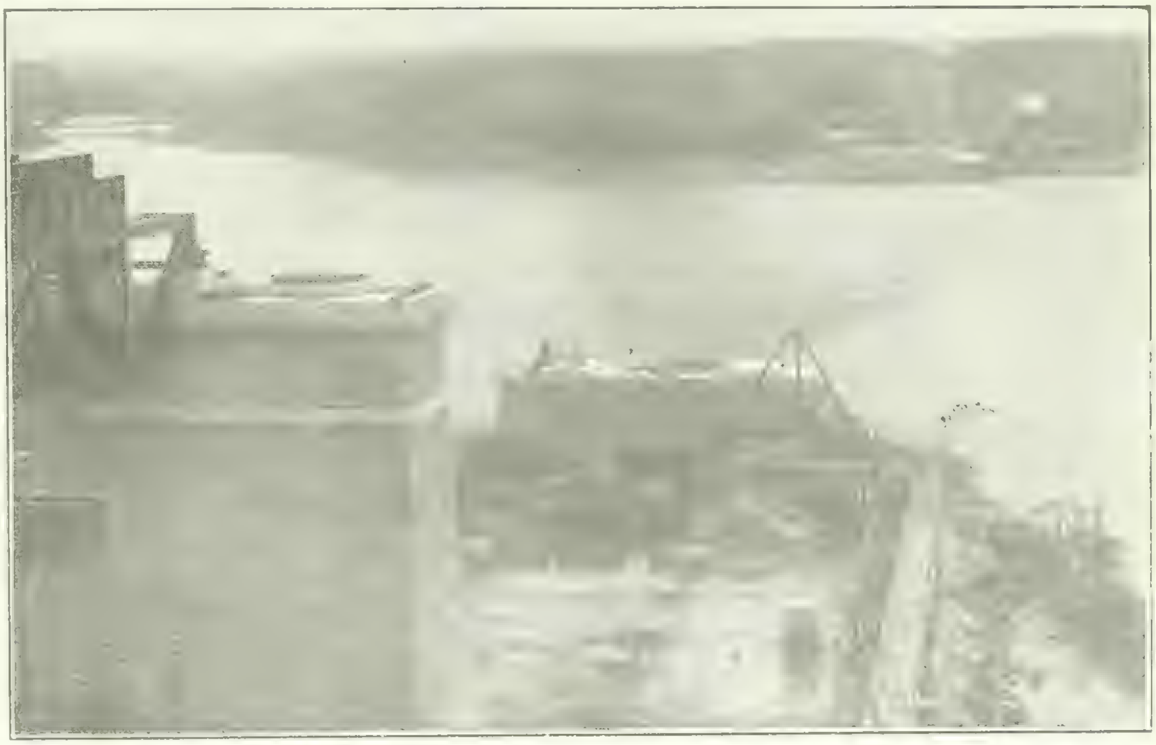

Fig. 1.—General view of the bridge site from the north shore, showing the completed masonry on both sides of the river.

Among the first things to be done in connection with the reconstruction was to take an extensive series of borings to ascertain the nature of the bottom and locate

bed rock. The latter was found to exist about 100 feet below high-water. It was also decided that the old masonry was not large enough to suit the new structure and it was therefore demolished and entirely new piers built.

The clearing away of the debris of the fallen structure was a somewhat difficult task, but it was finally accomplished by the aid of the oxy-acetylene torch and dynamite. At the present time there is little or no evidence to show that this accident had ever happened. There still remains, however, about 10,000 tons of the old bridge at the bottom of the river extending out from the shore over 800 feet. Tied down by this wreckage are the remains of some 60 or 70 men who lost their lives when the accident took place. As the water at this point is very deep and the wreckage is far below the requirements of navigation, this steel will probably remain for all time in its present location, as there is no known method of salvage at the depth at which it lies.

The most serious problem in the construction of the masonry was the sinking of the pneumatic caissons for the two main piers. On the south side a single caisson 180 ft. x 55 ft. in area was used. On the north side two caissons each 80 ft. x 60 ft. were sunk with a 10-ft. space between them, the pier being bridged over this opening. No serious difficulty was met with in the sinking of these caissons although the material on the north shore was very much harder to penetrate than that of the south.

The completed main piers at the present time, extending as they do about 25 ft. above the water, do not give evidence of the enormous amount of labor expended in their construction. As the north pier was driven 60 ft. and the south pier 100 ft. below the bed of the river, at a cost of approximately $1,000,000 each, some idea of their enormous proportions may be obtained.

The anchor piers show up more prominently, being entirely above high-water. These piers are 136 ft. long and 29 ft. wide and extend about 140 ft. above the surface of the ground, or higher than a 10-story office building.

The span of the Quebec Bridge is 1,800 ft. between main piers—the longest of any bridge in the world—being 100 ft. longer than that of the famous Forth Bridge in Scotland. The length of the suspended span is 640 ft., and the total length between abutments, 3,239 ft. The bridge has a clear height of 150 ft. above extreme high-water for a distance of 500 ft. at the centre of the bridge, in order to allow passage of ocean ships beneath. The bridge is 88 ft. wide centre to centre of trusses, or 21 ft. wider than the old bridge. The height of the main posts over the main pier is 310 ft., with an unsupported length of 145 ft. These posts weigh 1,500 tons each, the four of them costing in the neighborhood of $1,000,000. The height of the bridge above the floor at the main piers is about 180 ft. Some idea of the enormous proportions of this bridge may be gathered from the fact that a 16-story building could rest on the floor at this point and hardly extend above the tops of the main posts.

The steel shoe or pedestal carrying the main posts and other members on the main pier has a base with an area of approximately 22 ft. x 26 ft. It is 19 ft. high and weighs about 400 tons. The total reaction on each of these shoes amounts to 55,000,000 lbs. Some idea of this enormous force may be gathered from the fact that it represents the weight of 150 standard locomotives. If these locomotives were placed one upon the other they would extend to a height 15 times that of an ordinary 10-story building.

The bottom chord of the bridge weighs approximately 400 tons between main panel points. This has to be shipped in four pieces for shipment and handling during erection. The outside dimension of this chord near the shoe is approximately 7 ft. x 10 ft. 6 in. If it were not for the interior diaphragms and bracings, it would be possible for six or seven men to walk abreast throughout the length of this member.

Fig. 2.—View showing one web of double floor beam at the bridge site storage yard. These girders are 10 ft. high and 88 ft. c. to c. 11-inch pins are used to connect the 60-ton floor beams to the post.

The main post, as stated before, is 310 ft. high. It is approximately 9 ft. x 10 ft. in outside dimensions, and has an area of 1,902 sq. in. It is composed of four columns laced together, and requires to be shipped in 27 pieces and connected together in the field. The weight of the bridge will amount to about 65,000 tons, which weight exceeds that of the 200 bridges constructed on the National Transcontinental Railway. These bridges, if placed end to end, would extend over a distance of 11 miles. This weight is also about five times that of the new double-track C.P.R. bridge over the St. Lawrence at Lachine.

A proportion of the steel used in the bridge will be nickel steel, 40 per cent. stronger than the ordinary carbon steel used in other bridges. This nickel steel is used principally near the centre of the bridge where the weight is the greatest factor in deciding the size of the members.

The bridge is designed to carry two railway tracks, capable of carrying two trains weighing approximately 5,000 lbs. per lineal foot each. There are also two sidewalks for foot passengers. No provision has been made for highway traffic.

New shops have been constructed by the St. Lawrence Bridge Company, exclusively for the manufacture of this bridge, with special equipment and handling machinery, the whole costing in the neighborhood of a million dollars.* Up to the present some 9,000 tons of material have been manufactured and shipped to the site.

During the past season the contractor for the superstructure has got his plant in shape and has already erected the two north approach spans from the abutments out to the anchor pier. It is expected that during the coming season practically the whole of the north anchor arm will be erected.

The erection of this bridge is probably one of the greatest problems, calling for more engineering skill than any other structure of its kind in the world. Every feature of erection from the placing of the members to the driving of the rivets is worked out in detail, and is supplied in printed form in a bound book to the erecting superintendent. All engineering problems are therefore solved for the erection force before they start, their duty being simply to carry out the mechanical end of the work in accordance with positive instructions. To handle the huge members on the bridge itself during erection, enormous steel travellers will be used, one on each side of the river, each of which, with its machinery, will weigh over 1,000 tons. One steel traveller is at the present time nearing completion on the north shore. All the cranes and derricks on this traveller. are operated by electricity. The traveller runs on trucks and is moved from point to point on the floor of the bridge as the work progresses. This derrick is capable of lifting 55 tons on a boom 50 feet long. Everything about the mechanism and machinery has been made as nearly foolproof as possible.

In order that there may be no possibility of these heavy members being dropped and doing damage to the bridge or endangering lives, it is necessary to operate the hoisting engines against an electric resistance which means that the engines have to work just as hard to lower a piece as is necessary to raise it. Some idea of the size of the tackle used may be gained from the fact that the large blocks employed are about 5 feet in height, and weigh approximately 5,000 lbs. each.

One of the features of the erection which will probably be unique in the annals of bridge engineering will be the floating in of the centre or suspended span. This span will weigh about 5,000 tons and will be erected on trestles at some point near the bridge. When it is ready to be floated, very large pontoons will be floated under the span at low tide and when the tide rises will lift the entire span off the blocks. It will then be floated into position under the two ends of the cantilever arms at a low level and be connected up to these arms with long steel links. During this operation all navigation will be stopped in the river. When the connection has been made at the four corners at extreme high tide, the barges will settle with the tide and leave the span suspended. Powerful jacks of 2,000 tons capacity, situated at each corner of the cantilever arm, will then be brought into play and this span lifted slowly into place. It is estimated that the connecting up of the span should not take over an hour under good conditions and the span itself should be lifted into its proper position in about 48 hours.

Fig. 3.—View of one end of main bottom chord in twin vertical facing machine which faces both ends simultaneously. This chord is a ½-panel length and is shipped in two pieces. Fig. 4.—North shore traveller in course of erection. It is 200 ft. high and will weigh over 1,000 tons. Fig. 5.—One full panel length connected up for the reaming of the splice plates. The member, as it stands, weighs 400 tons. The heavy gusset plates taking a vertical tension and diagonal compression member is shown at one end.

The erection of the suspended span in this manner will save about one year in the time required for the complete erection of the bridge.

It is expected that the bridge will be sufficiently completed to allow traffic to proceed over it by the end of 1917.

---

*For full description of these shops see *The Canadian Engineer* for January 22nd, 1914.

There are many interesting features worthy of note in the shops of the St. Lawrence Bridge Company, mentioned elsewhere. Among the accompanying illustrations

Fig. 6.—North approach span erected. As the railway tracks on the bridge are 32 ft. centre to centre, these approach spans are erected as two separate bridges, each carrying a track.

there are several which convey a slight idea of the size and weight of some of the bridge members which these shops are turning out. Their proportions greatly excel

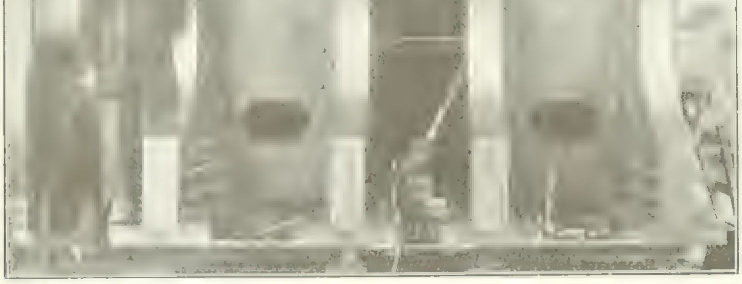

Fig. 7.—End view of member shown in facing machine. This end is bored for a 45-inch pin sleeve, which takes a 30-inch pin weighing 12 tons. Each of the webs are 7 inches thick at the pin. Manholes are provided at all diaphragms to allow contractors, painters, etc., to reach every portion of each member.

those of the product of any other shop removed any distance from the site. Moreover, the special machinery with which the plant is equipped for the rapid and accurate machining of special designs is in itself remarkable in its massiveness and adjustments. Among these various machines are the two planing machines, manufactured by James Bennie and Sons, Glasgow, with a capacity for plates up to 46 ft. in length. In them the heavy sheared plates have their edges finished, the cutting tools operating on both forward and return strokes.

The drilling and reaming are carried out on 16 stationary 7-foot radial drills, made by the Canadian Machinery Company, and 24 portable drills, transferred by cranes from one place to another. Shop rivetting is done for the most part by pneumatic yoke machines of 100 tons capacity.

A vertical boring mill manufactured by John Bertram and Sons Company, is used for boring large pin-holes and oval manholes. These large pin-holes, up to 4 ft. in diameter, are then finished in a horizontal boring machine with horizontal and vertical motions sufficient to permit the finishing of five of these pin-holes without resetting.

GRAND RIVER IMPROVEMENT.

SINCE the publication of the preliminary report of the Hydro-Electric Power Commission of Ontario on a proposed scheme or artificial storage and flood control on the Grand River, an exhaustive study of the flow characteristics of the river and its tributaries has been under way. The preliminary report appeared in *The Canadian Engineer* for April 17th, 1913. According to the 6th annual report of the Commission the investigation was begun in June, 1913, and at the present time gauging stations are established on the Grand River, and gauge recorders employed at each station to take readings of water level twice a day. This work has now been carried through one low-water season and some valuable information obtained. There has so far been a reasonably close relationship between gauge height and discharge. This satisfactory relationship has been mainly the result of low-water conditions, and there is unfortunately no likelihood that similar conditions will obtain during high stages of flow, when the gauges will be unavoidably affected by backwater.

In anticipation of the effect of back-water upon the gauges, a line of levels was run up the Grand River valley as far as Bellwood, and for several miles up each of the main tributaries. The work was started at Dunnville, using the U.S. Lake Survey level of Lake Erie as a datum. Permanent bench marks referred to sea level were established at convenient intervals on the main stream and tributaries.

During the course of the work all accessible Geodetic Survey bench marks were picked up, and in every case a very satisfactory check was obtained. A reasonable check was also obtained on various railway elevations.

All the gauges from which water level readings are being taken on the Grand River and tributaries are set from these bench marks, consequently all gauges are set to the same datum throughout the watershed, and slope data can be taken directly from the gauge readers' records. With the help of this slope data it is hoped that it may be possible to apply corrections to the gauge readings during high stages of flow, and thus eliminate to a large extent the effect of back-water.

THE MANAGEMENT OF SEWAGE DISPOSAL WORKS.

IN a paper which he read last month before the Institute of Sanitary Engineers at Westminster, Eng., Mr. John E. Farmer, engineer-in-charge of the sewage disposal works of the town of Croydon, presents the following notes on the operation of disposal works:

The works manager should look at the disposal of sewage in the light of a manufacturing process—the sewage discharged on to the works being the raw material and the final effluent the finished product. With regard to the financial aspect, a manufacturer must part with his finished product at a price that is greater than the cost of his raw material plus expenses of manufacture. With sewage disposal the raw material may be taken as being delivered to the works free of cost, and, there not being, except in a few cases, any saleable product, there is only the cost of manufacture of the final effluent to be taken into account.

There are two things to consider in the improvement of sedimentation tanks, i.e., the reduction of the amount of suspended matter in the tank effluent of the present designs, or to increase the volume now treated by the same tank capacity without increasing the solids in suspension, as now obtained. The former would lessen the work to be done by the process which follows, and the latter would save tank construction.

By placing a fine screen, such as 3/32 in. perforated zinc, between the tanks and the filters, it will save about three-quarters of the labor in cleaning the holes of the sprinklers, where such are in use, and also save much treading on the surface of the filter.

During a portion of the year there is some of the irrigation area fallow. The efficiency of fallow land is about one-third that of grass-cropped land where broad irrigation is the method; but where land filtration is in vogue the effect of a fallow period is not so great.

With an up-to-date plant for the purification of the liquid portion there are the solids to be dealt with; these have been a source of much trouble ever since sewage disposal was first put into operation.

The solids screened out and that deposited in the grit chambers are easier to deal with than the sludge, as they contain less moisture, and thereby more easily disposed of.

At Croydon all the solids are disposed of on the land—the screenings and grit by cart or trucks, the sludge by pumping—all being spread and ploughed in as manure. Lime is added to the sludge before pumping to reduce the smell and to accelerate the decomposition of the organic matter. The addition of 0.5 per cent. of lime reduces the smell about 75 per cent. The ratio of screenings and grit to sludge is 1 to 11.75, both in their wet state, or 1 to 2.8 in the dry state.

In the management of a sewage disposal plant, irrespective of the method of disposal, there should be kept records of all the different items showing the work done, thereby not only giving the present position, but enabling comparison with the past and information for the future.

The most valuable method of keeping the records is by diagrams. The usefulness of this method far outweighs the time and labor required to plot them, as the information for comparative purposes, so essential in tracing the cause and effect, which many times arises in the disposal of sewage, can be seen at a glance.

The main items for recording are: Volume of sewage and amount of rainfall; quality of sewage and effluents; amount of screenings, grit, and sludge; number of units working of the different parts of the process of purification; also the cost in wages, say, of the sludge disposal; irrigation; pumping, etc.

In keeping records there is obtained information that is of value not only to the management, but to the engineer in designing new extension works.

Combining the record of the hourly flow and the oxygen absorbed in four hours of samples taken each hour, one is able to find between which hours the greatest amount of impurity, as indicated by the above test, has to be dealt with.

Last, but not the least, item in the management of sewage disposal is the finding by observation and research the means of improvement in the present methods of purification, and also for the cause of the effect obtained.

Some work in this respect which I have done may be of some interest.

It has been known for years that a filter of fine-grade material gives better results in purification than one of coarse grade. Also some materials give better results than others. But there has not been, to my knowledge, any work done to definitely settle the cause of these differences.

One difficulty has been the want of means to measure the physical properties of the different materials used as a nidus for the bacteria. If this could be overcome, the point could be settled as to whether the cause of the difference between two different materials, when used as a nidus was due to greater absorptive powers of one than the other, or to greater surface area. The former used to be given as the reason by many a few years ago, but I think the latter is generally recognized as the reason at the present time.

To find the purification given by clinker as a nidus in a filter, as compared with gravel, a filter was constructed in two halves, one-half filled with clinker and the other half with gravel, in 1904, at Croydon.

The grading being the same for both materials, i.e., drainage tiles and 3 in. gravel = 9 in.; ¾ in. to 1 in. = 1 ft.; ¼ in. to ¾ in. = 3 ft. 3 in.; total, 5 ft. Area, 200 square yards; rate of working, 200 gallons per square yard per 24 hours. Fed by revolving sprinkler.

The average results of 31 samples taken between October 13th, 1904, and June 19th, 1905, are:—

	Tanks' Effluent.	Clinker ½.	Gravel ½.
Free ammonia as nitrogen..	5.747	0.665	4.148*
Albuminoid as nitrogen	0.360	0.068	0.166*
Oxygen absorbed, 4 hours..	4.157	0.914	1.843*
Chlorine	9.43	9.14	[illegible].71
Nitrates as nitrogen	—	4.529	1.265*
Nitrites as nitrogen	—	0.165	0.294*
Dissolved oxygen	[illegible]	5.8	[illegible]

*Parts per 100,000. †C.C.S. per litre.

The above results show that clinker gives much better results than gravel; but the question is, What is the cause of this?

To find the reason, I have carried out some experiments in the laboratory.

As regards the reduction of the impurity by passing over the surface, there must be taken into consideration that as the water passes downwards it gradually becomes less impure, so that after [illegible] surface

area it gives to the next a water which has less impurity than it received, so it is quite obvious that the same per cent. purification cannot be effected by the second area of surface, assuming they have both the same surface area.

From the experiments made one comes to the conclusion that the surface area of the material is the factor which governs the comparison between one material and another as regards its suitability as a nidus in a filter.

It may not be out of place, especially as I have mentioned it before, to give the physical property of materials for absorbing salt. During my experiments to obtain a method for estimating the surface retention, I found that all materials experimented upon absorbed a considerable amount of salt, and by extending the surface retention method this absorption could be estimated.

The following is a summary of the results: That with both clinker and gravel the amount absorbed per cube foot increases regularly with increased diameter of the particles. If this property was the cause of the difference in purification, as many believed it was, the purification would increase with the increase in size of the material; but the reverse has been shown to be the case. The management, after obtaining an effluent, has to observe its effect on the stream into which it is discharged, and there is a great probability that in the near future this will be one of the management's most important observations.

MINERAL PRODUCTION IN QUEBEC FOR 1913.

Substance.	Production, 1913. Quantity.	Value.	Value in 1912.
Asbestos, tons	136,105	$3,825,959	$3,059,084

There has been in recent years a steady increase in the amount of brick pavement laid in Rochester, last year's total being [illegible] square yards. However, the amount of asphalt pavement is still greatly in excess of any other kind. In 1913, 146,524 square yards of street asphalt were laid, while 121,700 square yards of creosoted wood-block pavement were laid in Manhattan borough, 20,000 square yards in Peekskill, and much smaller quantities in other boroughs.

REPORT ON COLLECTION AND DISPOSAL OF WASTE, TORONTO.

The Street Commissioner of the City of Toronto, Mr. Geo. B. Wilson, has recently presented a report on the collection and disposal of the city's refuse, together with a number of recommendations in connection therewith. The report has received the approval of the Medical Officer of Health for Toronto, and the Chief Health Officer of Ontario. In this report, it is assumed that the term refuse includes garbage, rubbish, and ashes; that the term garbage includes all kitchen refuse; and that the term rubbish includes all household waste other than ashes and garbage.

A summary is given as follows: It is recommended that the city construct a combined central plant at Ashbridge's Bay, where all garbage will be disposed of by the reduction process, and all rubbish incinerated in high-temperature furnaces. The power which is developed from the rubbish furnaces will be utilized in the reduction plant, and the gases deodorized.

An analysis of the studies made demonstrates that the disposal of garbage by reduction becomes more advantageous in future years, as compared with other methods of disposal.

The reduction method for the disposal of garbage requires a larger capital cost, but with all items considered, will require a much lower net annual cost.

All work contemplated will be developed on a comprehensive scale, and with reference to future needs.

The development of any method for collection and disposal of refuse should also consider all branches of work carried on by the street cleaning department, with special attention to operation and unit cost-keeping.

The equipment used in collection of refuse should be installed with special regard to work to be done, from the standpoint of sanitation and economy.

All refuse, so far as possible, should be removed from the premises (and not placed on the curb), so as to eliminate the unsightly appearance of streets on collection days.

In making separate collections of refuse, co-operation will be required on the part of the citizens, as well as the strict enforcement of regulations by the department of street cleaning.

It is recommended that the condition of the present stables, yards and shops should be remedied by the construction of adequate buildings, to enable the department to satisfactorily conduct all branches of the work.

Early action is desired, to relieve the present conditions.

The question of garbage and refuse disposal received considerable attention at the hands of Mr. R. C. Harris during the period in which the service was under his control. It was reported upon by him in 1912 and as a result a by-law was passed in January, 1913, authorizing the expenditure of $1,000,000. The matter remained in abeyance, however, until the reorganization of the present department in May, 1913. Since that time, Mr. George B. Wilson, Street Commissioner, realizing the importance of the step to be dealt with and the necessity of an early solution, has given the problem a thorough investigation. In October, 1913, he acquired the services of Mr. I. S. Osborn, an engineer experienced in the methods of collection and refuse disposal as practiced both in America and Europe. Since that time Mr. Osborne and his staff have prosecuted the necessary preliminary investigation without interruption.

The problem of waste disposal naturally involves, among other things, a complete study of the methods and costs of collection, the equipment required for such collection, and the population to be served in the different sections of the city at various periods. Recognizing that the solution of the refuse problem in itself would only afford a partial relief from the conditions which prevail throughout the city it was decided to include in the investigation a study of present stable, shop and yards requirements as well as studies of collection methods and equipment.

Concerning the methods of collection the report makes the following reference:

Collection Methods.—Great advance has in recent years been made in this manner of collecting waste in many of the European cities, and so far as possible, such changes as are to be made in the collection methods of the department, will be carried out with the idea of eliminating the undesirable features, which at present obtain. The methods of collection adopted will depend on the conditions to be met, and will necessitate considerable study and practical experimenting. This can only be undertaken when the method of disposal has been definitely determined.

Irrespective of the manner of disposal adopted, it will be necessary to continue to dispose of ashes as at present, viz., as filling for low lands. This being the case, the cost of collecting ashes will remain constant, and has, therefore, no bearing on or influence in determining the method most advantageous in the collection and disposal of other classes of waste.

The points to receive attention are as follows:

(1) The removal of waste from the premises in such manner as to eliminate the unsightly appearance of the streets on collection days, where receptacles are placed on the curb and remain there during the day.

(2) Type of equipment used in collection to be such as will prevent the scattering of material on the streets, and the creation of dust when contents are being discharged from receptacle into wagon.

(3) The improvement in type of receptacle; the ideal condition being, of course, a standard container.

(4) The development of collection methods from a sanitary and economical standpoint. (The greatest cost in making collections results from the time required to load, due to equipment remaining idle while material is being picked up.)

When disposal is made by incineration, a combined collection of garbage and rubbish is usually made. This requires the householder to provide a receptacle for the material in a combined state, and relieves the tenant of the trouble of making a separation at the house.

If disposal is made by the reduction method, it will require the householder or tenant to keep garbage entirely separate from rubbish.

It must be borne in mind that in changing from a combined collection of garbage and rubbish, to a separate collection, separate collection wagons for each class of refuse, as well as separate containers for each class, will be required.

Unless there be hearty co-operation on the part of householders, and they are educated to render assistance, it will be difficult to obtain the desired results, since without proper separation, the costs of reduction will be increased, and with a combined collection the reduction of garbage will be positively prohibitive from a practical standpoint. The adoption of this method will mean the strict enforcement of regulations governing garbage collections on the part of this department.

Climatic conditions tend to make separate collections in Toronto difficult, as during the winter months, unless well drained, garbage will freeze in the containers, though with due care in the draining of garbage before it is placed in the container, and the use of paper, this may be eliminated to a very large extent.

When garbage is mixed with rubbish, it is necessary from a sanitary standpoint to make more frequent collections, whereas with separate collections, a more frequent collection of garbage could be made if deemed advisable, and a less frequent collection of rubbish.

When separate collections are made, a wagon having a much larger capacity than our present carts, can be used to advantage for the collection of rubbish, the size being limited to a wagon that can be handled in the places where collections must be made.

It is the intention of the department to experiment with what is known as the "Roller System," whereby cans are brought from the house to the curb by men in advance of the collection wagons, and, after the material has been placed in the wagon, the empty cans are returned to the premises by men who follow up. It is expected that this will permit of the more satisfactory and expeditious loading and removal of the material.

It has been assumed by the department in its estimates of costs that the present practice of requiring the householder to place the receptacles on the curb will be done away with, and that all collections, where possible, will be made from the premises. This will eliminate the unsightly appearance of the streets, due to the fact that receptacles frequently remain from morning until night on the streets on collection days. It will, however, relieve the householder of the trouble of placing the can on the curb and returning same after its contents have been emptied.

Costs of Collection.—In estimating the cost of collection, many items will of necessity have to be considered, such for example as the type of equipment used, and the advantage of the same as to loading and unloading; the size of the wagon used in making collections for each class of material, and the maximum load of each class of material which can be economically placed on each wagon.

The costs will vary under different conditions, with the different types of equipment used. For example, the cart which is now in use will permit a man to load the material at a less cost per ton than the same work could be done by one man using a team and wagon. This is due to the increased cost of the team and wagon over the one horse and cart.

The productive cost of the man and cart as now operated by the department, amounts to approximately \$4.33 per day, while the cost of the team and wagon, with driver, amounts to \$5.83.

One man will load as much material per hour on to a cart as he will on to a wagon, so that the cost of loading, under similar conditions, increases where the wagon is used, but as the wagon will hold considerably more material than the small cart, if of proper capacity, the cost per ton mile will decrease in proportion to the weight carried. For example, the material can be placed on the cart at a less cost per ton than it could be placed on the wagon (both remaining idle meanwhile), but with increased capacity of the wagon, the quantity hauled by it will decrease the cost per ton mile [illegible]. It is, there-

fore, obvious that with any great distance to be travelled, the wagon will show a considerable saving, due to its larger capacity.

In this connection, it must be evident to all citizens that the carts at present in use by the department are taxed beyond their capacity, and are thereby rendered unsightly in appearance in collecting from house to house and travelling our public thoroughfares. It must also be evident that before the load can be collected, and the canvas placed on the cart, more or less of the material is scattered on the streets, thus rendering them untidy, particularly in the residential sections, and throwing an extra burden on the street cleaning section of the department.

As already stated, the type of equipment to be recommended for adoption will, to a great extent, depend upon the method of disposal determined, and so soon as convenient after this question has been settled, studies will be made, using various types of equipment for collection by various methods, with a view to installing that which is found to be most suitable from a sanitary and economical standpoint.

Methods of Disposal Considered.—(1) Total incineration of all rubbish and garbage, and such quantity of ashes as required for their fuel value, the bulk of the ashes being disposed of as fill; and (2) Total incineration of rubbish, and reduction of garbage, with ashes disposed of as fill.

The results of the studies made were applied to twelve projects, assuming possible locations of disposal plants or loading stations for the transfer of refuse to a central plant by steam railways, electric trolleys, or motor trucks.

In considering the method of total incineration in high-temperature furnaces, the combustion gases, where possible, should be used in generating power, but due to the price at which electric current is furnished by the Hydro-Electric Commission, it is not feasible to generate electric current from power that can be developed in the refuse furnaces, since to do so would not warrant the additional first cost of installation, or increased cost of operation. It has not been possible to find any outlet for the utilization of steam, inasmuch as at such locations as the quantity produced might be profitably utilized, the demand would not be constant. Again, where the demand would be constant, suitable sites are not available for the installation of furnaces.

Of the 12 projects investigated, 3 of them appearing the most feasible are summarized in the report according to the accompanying table.

The report recommends the adoption of project "C" which provides for the total incineration of rubbish and reduction of garbage in a combined central plant erected at Ashbridge's Bay, the material to be transferred thereto from three loading stations in the western, northwestern and northern sections of the city.

It is proposed, under the method of disposal recommended, to have all material collected delivered to the loading stations, and thence transferred either by steam railway, electric trolleys, or motor trucks, to a central disposal plant located at Ashbridge's Bay, except the rubbish and garbage collected in the territory adjacent to the central plant, which will be delivered by the collection wagons direct. The garbage will all be scientifically treated in a reduction plant, the rubbish incinerated, and the power developed from the rubbish furnaces used in operating the reduction plant, the high temperature produced being utilized to deodorize the gases.

The central plant at Ashbridge's Bay (assuming the adoption of the department's recommendation), will consist of an unloading building, in which all garbage delivered at the plant will be unloaded. All handling of material as delivered will take place in this building. The garbage from the unloading building will be delivered into reduction machinery in the reduction building, where it will be broken down by heat in enclosed equipment, and not exposed until thoroughly sterilized.

The free grease and water will be separated from the solids in the reduction building, the solids being delivered to drying building, and the water and grease to the grease separating building. The grease will be separated by gravity from the water, and the remaining

Summary of Three Proposals.

Project.	Capital cost.	Collection			Disposal			Fixed charge	Revenue			Net Annual Cost		
		1913	1918	1923	1913	1918	1923		1913	1918	1923	1913	1918	1923
A—Total incineration of all garbage, rubbish and part of the ashes, in two, three or four disposal plants.	$480,000	143,061	199,443	280,870	64,145	85,863	114,953	37,056	None	None	None	244,262	322,362	432,870
B—Total incineration of rubbish in two incinerators, and reduction of garbage outside city	$676,000	180,563	264,667	368,707	127,422	150,437	206,110	52,187	159,492	213,468	285,637	200,680	253,823	311,307
C—Total incineration of rubbish and reduction of garbage in central plant located at Ashbridge's Bay.	$720,000	173,081	240,531	341,887	112,164	149,007	193,502	55,584	159,492	213,468	285,637	181,037	231,654	305,346

water concentrated by evaporation, to recover the solids that are held in solution, and which in turn will eventually be dried with the other solids to produce a by-product, known as tankage.

The solids as delivered from the dryers in a dry state, will be delivered to the extraction building, where recovery of remaining grease will be made by a solvent.

By the treatment described, all solids originally in the garbage will be recovered, as tankage and grease, and ready for sale or shipment.

The rubbish will be delivered to incinerator building, where it will be burned. The furnaces for this purpose will be connected with boilers, so as to develop steam to be used in reducing the garbage. In addition to the boilers installed for generating steam from rubbish, boilers will be installed for use of coal to supply such additional steam as may be required to complete the process of reduction.

During the operation, all material, so far as possible, will be sealed during the process of disposal, and the gases and steam trapped, so as to pass them through deodorizing scrubbers, and such gases as are not deodorized in the scrubbers, will be exhausted and passed through the rubbish furnaces, where they will be deodorized by being subjected to a temperature of from 1,200 degrees to 2,000 degrees F. It is also intended to exhaust the air from rooms which might contain odors, and to utilize the air so exhausted to supply a draft on the rubbish furnaces.

A SHORT LINE FROM THE MARITIME PROVINCES TO THE QUEBEC BRIDGE.

Surveys have been completed for the construction of what will be known as the Quebec Extension Railway to run from Washburn, Me., through a distance of 110 miles in the State of Maine and 64 miles into the Province of Quebec. The intention is to ultimately continue the road to the Quebec Bridge, connecting there with the transcontinental roads from the west and furnishing a short line from it to the Maritime Provinces. The line will be operated throughout by electricity.

Another electric line, the Aroostook Valley Railway, runs from Washburn, Me., and will afford connection at Presque Isle, Me., with the Canadian Pacific Railway to St. John, N.B.

Mr. S. B. Wass, assistant chief engineer of the St. John and Quebec Railway, is chief engineer of the new project. From him we learn that the construction of the line will include two large bridges of approximately 600 ft. in length over the St. John and Alligash Rivers, and also an 80-foot bridge at Beaver Brook. The Canadian Eastern Construction Company, who have been awarded the contract, will likely begin operations during the coming summer.

The C.P.R. owns or controls 18,000 miles of railway. Its own system is comprised of 13,280 miles, and the Minneapolis and Duluth roads account for some 4,000 miles of track. It has still about 700 miles of spur lines and extensions to build in the west; while the double tracking will mean an addition of over 4,000 miles of railway.

The state of Minnesota has attained a position in the first rank as far as road improvement is concerned. In 1914, the state will spend $2,5[illegible] upon roads and bridges, and will inaugurate a system of road patrols for the maintenance of its roads. Nearly 1,500 patrolmen will be assigned to 5 and 8-mile sections of the state highways, and will be held responsible at all times for the condition of the roads.

GRAPHICAL SOLUTION OF THE THREE-POINT PROBLEM.

A GRAPHICAL method of solving on the plane table the three-point problem in hydrographic surveying was given recently by Mr. A. L. Higgins in "Engineering," of London, Eng. His solution is the extension of the well-known method of "two intersecting circles," and is outlined as follows:

Problem.—Given a, b, and c, the plotted positions of three points A, B, and C, and θ and ϕ, the angles subtended at P by A B and B C respectively; to determine p, the position of P on the map (Fig. 1).

Solution.—From b draw lines b e, b f, making the angles a b e, c b f respectively equal to 90 deg. — θ and 90 deg. — ϕ. At a erect a perpendicular to a b, intersecting b e at e; at c erect a perpendicular to b c, intersecting b f at f. Join e f. Let fall a perpendicular from b on e f; this will meet e f at the required point p.

Proof.—On e b and e f as diameters (centres o and o' respectively) describe circles; these will intersect at p, the common apex of two adjacent angles equal to the observed angles θ and ϕ. For, being angles in the same segment of a circle, the angle a e b is equal to the angle a p b, and the angle c f b is equal to the angle c p b. And the angle a e b is by construction equal to θ; therefore the angle a p b is equal to θ. Similarly, the angle c p b is equal to ϕ.

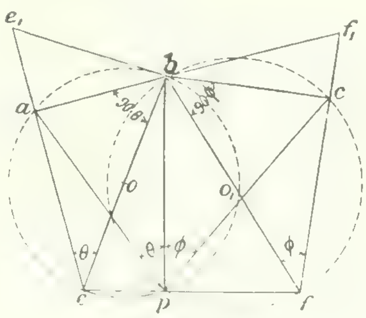

Fig. 1.

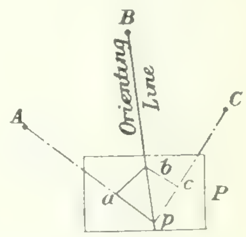

Fig. 2.

The above construction is more expeditious in the office than the one from which it is derived. It is readily effected on the plane table in a manner hereafter described.

The Analogous Plane-Table Problem.—Given a, b and c, the plotted positions of three visible points A, B and C, to determine p, the plotted position of P, the station occupied by a plane table.

(This notation is retained throughout the remainder of this article.)

Here the angles θ and ϕ (Fig. 1) are involved graphically, but the fundamental principle of the plane table precludes the necessity of observing their magnitudes.

The "three-point problem" involves the dual process of

1. "Orientation"—i.e., setting the board so that the several plotted lines are parallel to, or coincident with, the directions of the corresponding lines in the field.

2. Plotting p, the position of the station occupied. (This is a separate process (resection) in the case of Bessel's graphical solution.)

Although possessing the same characteristic—that of plotting the station occupied—this problem cannot appositely be termed a special case of resection, since the application of that method pre-supposes direct means of orienting the board—a ray drawn in the direction of P

at a previous set up over one of the three points A, B, or C.

Thus, for an example of resection, suppose a surveyor has a plane table oriented over B, and a picket at P to indicate a station selected for detail work. Before removing the table he draws a ray through b, the plotted position of B, in coincidence with the line B P, as a direct means for orientation at P. The required point p is somewhere in this ray. He then sets up over P, and orients the board by sighting at B, with the fiducial edge of the alidade along the ray through b. The board oriented and clamped, he determines p at the intersection of the line sighted through a to A with the ray through b to B. As a check he would centre the fiducial edge on c, sight at C, and note if the line thus drawn also passes through p (Fig. 2). But, as far as the three-point problem is concerned, the three points are virtually inaccessible; direct orientation is therefore precluded, and resort must be made to one or other of the mechanical, graphical, or trial solutions.

Some years ago the writer observed that the extended hydrographical solution (Fig. 1) might be readily adapted to the analogous plane-table problem, with special application to cases in which the angles subtended at P by the points A, B, and C, were large, and, in consequence, frequently necessitated additional construction in the application of Bessel's method. Not only

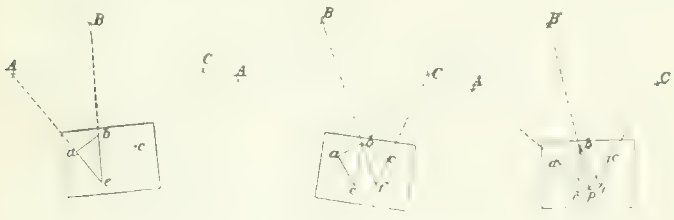

Fig. 3.

was this advantage manifest on trial, but the facility of soon estimating whether a station selected at random was within the limits of plotting, the reason of which is inherent in the fact that the required point lies in the line of two previously determined intersections.

The field routine of this method is as follows—

(The three positions of the board in Fig. 3 correspond to the three principal steps.)

First Step.—(1) Level up the table over P, the station selected, and draw a line perpendicular to a b at a. (This corresponds to erecting the perpendicular a e in Fig. 1.) (2) Place the fiducial edge of the alidade ruler along this perpendicular, and sight through a at A, the corresponding point in the field. Clamp the board in this position and repeat the sight as a check against movement. (3) Fix a pin in the board at b, and, keeping the fiducial edge against this pin, turn the alidade until the point B is seen bisected by the cross-hairs of the telescope, or, in the case of a sighted alidade, coincident with the sighting slits. Draw a line along the fiducial edge to intersect the perpendicular in e. (Thus at e, θ, the angle subtended by A B at P, Fig. 1, is set out graphically, the board being regarded a point in comparison with the area surveyed.) (4) Unclamp the board.

Second Step.—(1) Draw a line perpendicular to b c at c. (This corresponds to erecting the perpendicular c f in Fig. 1.) (2) Place the fiducial edge along this perpendicular, and sight through c at C. Clamp the board in this position, and take a check sight against movement. (3) Turn the fiducial edge about the pin at b until the point B is seen bisected by the cross-hairs of the telescope, and, holding the alidade in this position, draw a line along the fiducial edge to intersect the perpendicular from c in f. (Setting out the angle ϕ graphically at f, Fig. 1.) (4) Unclamp the board.

Third Step.—(1) Place the fiducial edge through the points e and f, and slide a set-square along that edge to p, the foot of the perpendicular from b on e f. (This corresponds to joining e and f, and letting fall the perpendicular from b on that line.) (2) With the fiducial edge through p and b, orient by sighting at B in the direction p b; clamp the board in this position, and check the accuracy of p by sighting through a to A, and through c to C. (Checking by resection.) No "triangle of error" should result—i.e., the rays passing from A, B, and C through a, b, and c respectively should definitely intersect at p.

Notes.—(1) When the station P is situated on the circle through A, B, and C, the problem is indeterminate. This case is evident when the lines b e, b f coincide, but in practice the limit is reached when the angle e b f is very small.

(2) When one or both of the angles subtended at P are greater than 90 deg. (as is the case when P is within the triangle formed by A, B, and C) obtain the intersection e_1 or f_1, or both, as the case may be, by producing backwards one or both of the perpendiculars at a and c (Fig. 1).

(3) When one or both of the intersections e and f cannot be obtained within the limits of the board, the point p may also be indeterminate for the stations selected. The likelihood of this result should be judged (by estimating the position of the line between e and f) before resort is made to the following construction:—

Erect perpendiculars at the middle points of the lines a b and b c—i.e., parallels to a e and c f, to intersect the lines from b to e and f in, say, o and o^1 respectively (Fig. 1). Let fall, as in text, a perpendicular from b on the line joining o and o^1, and, using this as a means of orientation with respect to B, determine by resection the position of p.

Bisection.—Any convenient ratio other than one-half may be chosen, provided that the lines a b, b c are proportionately divided from b.

CANADIAN INLAND WATERWAYS.

Preparation on the part of the Government for the construction of a new canal at Sault Ste. Marie indicates the magnitude of the scheme to improve the navigation of Canada's great waterway of the St. Lawrence and the Great Lakes. It is now evident that besides the new Welland Canal another will be built at the Soo, and the St. Lawrence canals deepened so that all will be equal in facility and size for handling the greatly expanding traffic. The new Welland Canal will have a depth of 31 feet, which can be increased 4 feet without rebuilding the locks, so that this waterway is eventually intended to accommodate vessels of 35-foot draft, or equal to many of the large liners now running between Montreal and Liverpool. The Soo Canal will be constructed of an equal depth, and the improvement of the St. Lawrence canals will give Canada a waterway from the ocean to Fort William that the largest ocean freighters can navigate. Cargoes will not need to be broken as they now are at Port Colborne, Kingston and Montreal. Toronto Harbor must be completed in four years. By this time the new Welland Canal will be ready for traffic, and from the activity of the Government it is certain that along the whole length of this great waterway the improvements on the canal systems and harbors will either be completed or nearing completion.

PARAFFIN BODIES IN COAL TAR CREOSOTE AND THEIR BEARING ON SPECIFICATIONS.*

By S. R. Church and John Morris Weiss.

IN specifications for coal tar creosote there is usually a paragraph stating that the oil shall be a pure product of coal tar, and free from adulteration with any oil or products from any other tar. The purpose of this clause is usually to provide against admixture with petroleum products, such as water gas tar or oil tar derivatives. In the present paper the writers wish to consider one requirement which is sometimes introduced with the object of enforcing this provision.

Coal tar is made up mainly of aromatic compounds, and the presence of bodies belonging to the saturated paraffin series has been regarded by some as direct and unmistakable evidence of contamination of coal tar creosote by distillates from other tars.

Dean and Bateman[1] proposed a sulphonation test for creosote oils, based on the principle that aromatic hydrocarbons dissolve in concentrated sulphuric acid to sulphonic acids, while bodies of the paraffin series remain unattacked. They applied this test to numerous creosote oils, and concluded that any oil yielding a sulphonation residue was contaminated with products of other source than coal tar.

A modification of this test, devised by J. M. Weiss, was proposed in an article by S. R. Church,[2] which did not in any way change the results of the test, but merely made it easier of operation, so far as the detection of traces was concerned. Later, Bateman[3] made further modifications in the test, which made it a still more convenient laboratory operation. This modification was endorsed by Church[4] after trial as more convenient and practical than the earlier proposals.

Chapin[5] proposed the substitution of a dimethyl sulphate test to be used to determine paraffin hydrocarbons in creosote oil, as well as in creosote oil dips. Reeve and Lewis[6] have used this test, and have given a number of results obtained by it.

A brief description of the tests in question may be useful in this connection:—

Sulphonation Test.—"Ten cubic centimeters of the fraction of creosote to be tested are measured into a Babcock milk bottle. To this is added 40 cubic centimeters of 37 times normal sulphuric acid, 10 cubic centimeters at a time. The bottle with its contents is shaken for two minutes after each addition of 10 cubic centimeters of acid. After all the acid has been added, the bottle is kept at a constant temperature of from 98° to 100° Centigrade for 1 hour, during which time it is shaken vigorously every ten minutes. At the end of an hour the bottle is removed, cooled and filled to the top of the graduation with ordinary sulphuric acid, and then whirled for 5 minutes in a Babcock separator. The unsulphonated residue is then read off from the graduations."

Dimethyl Sulphate Test.—"Five cubic centimeters of the fraction is pipetted into a narrow 25 cubic centimeter burette, and shaken with 8 cubic centimeters of dimethyl sulphate after closing the burette with a smooth, close-fitting cork. Separation of the residual oil occurs in a short time in the form of a clear, almost colorless, supernatant liquid layer."

* Presented before Section D of the American Association for the Advancement of Science at the Atlanta Meeting, December, 1913.

We will first briefly discuss the relative merits and demerits of the sulphonation test and the dimethyl sulphate test, and then consider in what manner the results of such a test should be interpreted, particularly as regards creosote oil specifications.

We have made some experiments, using the dimethyl sulphate test, as recommended by Chapin, and the modified sulphonation test with fuming sulphuric acid and the Babcock bottle, as proposed by Bateman. Average samples of coal tar oil and water gas tar oil were distilled, and fractions taken from 240° to 270° Centigrade, and from 270° to 300° Centigrade. These fractions were then subjected to the dimethyl sulphate test and the sulphonation test, with the following results:—

	Sulphonation Test Residue.	Dimethyl Sulphate Test Residue.
Coal tar distillate, 240-270° C....	1.2%	0
Coal tar distillate, 270-300° C....	2.0	0
Water gas tar distillate, 240-270° C.	4.0	0
Water gas tar distillate, 270-300° C.	6.8	0

Further tests on other oils were also made, with the following results:—

	Sulphonation Test Residue.	Dimethyl Sulphate Test Residue.
Water gas tar distillate, 240-270° C.	2.4%	0.0%
Water gas tar distillate, 270-330° C.	1.2	0.0
Mixed tar distillate, 240-270° C...	2.0	0.0
Mixed tar distillate, 270-330° C...	3.0	0.0
Blast furnace tar distillate, 240-270° C.	17.6	23.0
Blast furnace tar distillate, 270-330° C.	23.2	38.0
Oil tar distillate, 240-270° C.....	14.4	22.0
Oil tar distillate, 270-330° C.....	18.8	28.0

It can be seen from these results that the dimethyl sulphate method showed no residue in many oils that gave measurable residues by the sulphonation method, and we feel that the former test is of no value, so far as the detection of small amounts of saturated hydrocarbons in the presence of aromatic hydrocarbons is concerned. Undoubtedly, if there were considerable amounts of petroleum or blast furnace tar distillate present, where there might be a sulphonation residue of from 10 to 20 per cent., the dimethyl sulphate test would detect it, but where there is only a question of comparatively small admixtures of material, itself low in sulphonation residue, this test would not seem to be of any value.

We have experienced great difficulty in obtaining dimethyl sulphate; moreover, we find that it rapidly changes on standing, so that fresh supplies must frequently be had. Another objection to this reagent is the danger attendant upon handling it.

In a great deal of our laboratory work on oils distilled from various kinds of tar, the results have been clouded by uncertainty as to the authenticity of the sample. Some time ago, therefore, we procured samples of tars from typical coke ovens and gas plants under such conditions as to make accidental contamination or admixture practically impossible. These tars were distilled to pitch, and the distillate oils recovered. The oils were subjected to a number of tests, partially along the lines of Dean and Bateman's work (loc cit). It is not our intention to give the details of this work at present, except in so far as they affect the question of the sulphonation test.

Coal tars may be divided into two classes:—

1. Coke oven tars, which may be further subdivided according to the type of oven in which the coal is carbonized.

2. Gas works tars, which may be divided similarly into horizontal, inclined and vertical gas works tars.

In this investigation we had one or more samples from each of the different types of installation, both coke oven and gas works, and have, we believe, examined a sufficient number of samples to draw correct conclusions.

The examination of the oils, which is of interest in this connection, was a Hempel distillation (made in accordance with the Forest Service method for analysis of creosote oil), taking fractions at the following points on the Centigrade thermometer: 210°; 210-225°; 225-235°; 235-245°; 245-255°; 255-265°; 256-275°; 275-285°; 285-295°; 295-305°; 305-320°; 320-330°. These fractions were then subjected to the sulphonation test, using Bateman's modified, as described above. In the appended table are given the results of these tests of the various oils examined, representative tests of each type of installation being selected. Where there were any great variations between oils of the same origin, the tests of the two most widely divergent materials examined are given:—

A consideration of the creosote oil specifications in active use indicates a tendency toward the use of the sulphonation test. The requirements of the test vary widely; in one case, the sulphonation residue is limited to 10 per cent. in others, to 1 per cent., while still others specify that in the fraction 300° to 360° C. it shall not exceed 0.25 c.c.

In a Forest Service Circular C. P. Winslow[7] gives the requirement for Class 1 and Class 2 coal tar creosotes, which are the only ones considered by him as pure coal tar creosotes, that there shall be no sulphonation residue. In "mixed coal tar creosotes," he allows, in Class 1, 10 per cent. of the 305-320° C. fraction as a sulphonation residue, and in Class 2, 20 per cent. of the fraction 305-320° C., expressing it in the form that "the volume of the sulphonation residue in cubic centimeters should not be greater than one-tenth or one-fifth, respectively, of the weight of the fraction in grams."

In the opinion of the writers, the requirement of no sulphonation residue is unfair as a basis of classification of pure coal tar creosote; and a very high limit for mixed creosotes, such as 10 to 20 per cent., is useless, as it makes it unnecessary, *per se*, to have any coal tar creosote at all present, in view of the fact that a great majority of the water gas tar distillates have considerably less than this amount of sulphonation residue in any fraction. If a requirement for no sulphonation residue should be enforced, only straight coke oven tars could be used to produce such creosote oils, and this is certainly a commercial impossibility for the most part. If a limit of 1 per cent. is set, the coke oven tar oils and some of the horizontal gas works tar oils would meet the requirement, but some of the latter would require the admixture of coke oven tar oils to bring the percentage below this limit. Also, if a tar distiller should be handling considerable quantities of inclined or vertical gas works tars, oils containing as low as 15 to 20 per cent. derived from these tars might fall outside of the 1 per cent. sulphonation residue limit.

The writers feel that a fairer limit for such specifications would be about 2 per cent., as this would not bar any normal coal tar creosote oils, and would at the same time prevent the admixture of petroleum products (other than those from water gas tar), blast furnace oils, etc. The admixture of water gas distillates will, of necessity, have to be taken care of in some other way than by the sulphonation test, as it is very plain that certain mixtures of coke oven tar oil and water gas tar oil of a low sulphonation residue, would show a lesser sulphonation residue than most oils obtained wholly from gas works coal tars.

We believe, moreover, that we have demonstrated the sulphonation test of itself to be of comparatively little value in detecting the admixture of oils of petroleum origin, particularly those derived from water gas tar, with creosote oil.

In a later paper we intend to publish additional data from our analyses of authentic tars, indicating the value of certain other tests, as means of determining the origin of oils used for creosoting.

PIPE CONDUITS MADE OF CONCRETE.

An economical method of constructing efficient and durable conduits of concrete for small steam lines is described in a recent issue of "Power," from which the following illustrations and remarks are reproduced:—

The trouble experienced in installing and maintaining steam lines underground is well known, especially where cinders have been used for grading. To lay a pipe line in cinders means a continuous digging up and renewing of pipes, for the life of wrought-iron or steel pipe in cinders is short and cinders alone make a poor insulator.

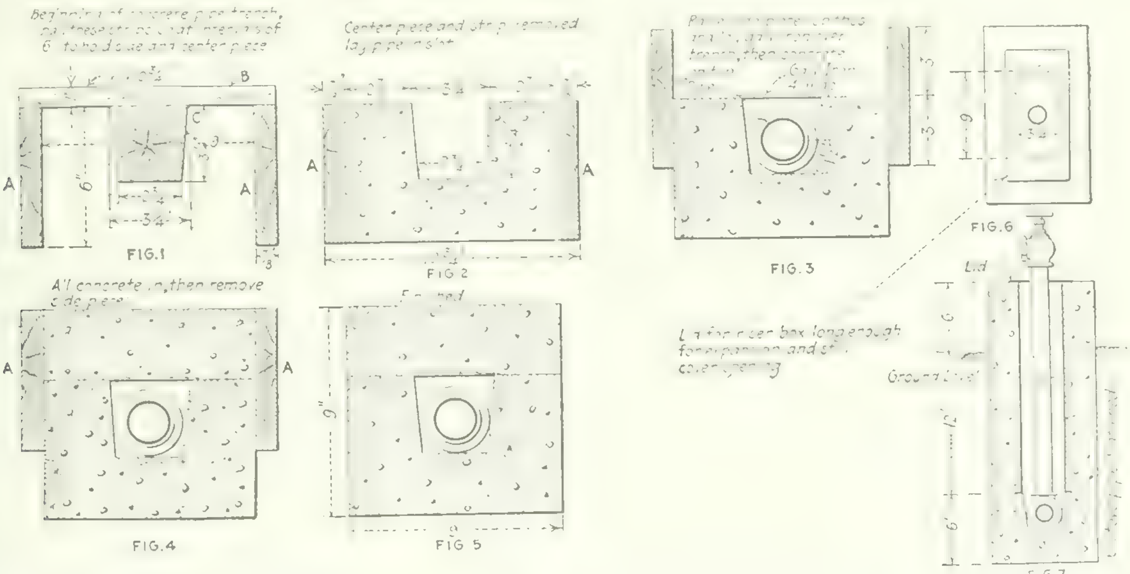
Some kind of covering must be employed to save the pipe and to prevent condensation. After using several kinds of material, including tin-lined wood casing, ordinary tile, split tile, and oak, pine, cypress and other kinds of wood coverings, each has been found to have its faults. Concrete conduits have been used for air and oil lines, there being little expansion or contraction, but providing for a steam line is a different proposition. With the knowledge gained in laying approximately 17,000 ft. of air lines in concrete, and knowing that it was immune from disintegrating action of the elements and of the cinders, a similar conduit for steam pipes was employed. It is very simple and less expensive than others, and to those who would keep down the cost of maintenance and raise the standard of service, our manner of providing conduits for small sizes of underground steam pipes may be of interest.

A method of providing for a 2-in. steam line would be to first dig a trench the required size and depth, and set in it two ⅞ x 6-in. fence boards *A*, Fig. 1, placed on edge, 9 in. apart. Next, nail a piece *C*, used as a core for forming the slot in the centre, to the strips *B*, 1 x 1 x 10¾ in. spaced 6 ft. apart, and tack them to the side boards. The ditch is then filled with concrete in sections, each about 12 ft. long, made of 10 parts of small stone or gravel, five parts sand and two parts cement. Mix the concrete to a slush and fill the form level with the top. Do not trowel the top, but use a broom to roughen the top surface, as the top will adhere better than if slicked with a trowel.

When the concrete is set, and it will generally harden enough in 12 hr., remove the strips *B* and lift out the centre core, leaving the concrete as shown in Fig. 2.

Now lay the pipe, as shown in Fig. 3, and cover the slot with a strip of thin galvanized or stove-pipe iron about 4 in. wide. Raise the side boards up 3 in., tamp dirt around the outside to hold the boards in place and fill with concrete to the top of the side boards, as in Fig. 4. When the concrete has set dry, remove the side boards, leaving the finished conduit of section like Fig. 5. If the ground is likely to hold water after a rain, it is well as an extra precaution to coat the sides and top of the conduit with hot coal tar, or with a heavy paint.

Care should be used where the risers come above the ground. For such places use a piece of 7-in. stove-pipe of the right length, split and flanged over at the lower end, and flatten the sides so as to leave space for the steam line to expand. After placing the stove pipe over the riser, set a box 9 x 15 in. around the stove pipe, both extended about 6 in. above the ground line, and fill with concrete, as in plan, Fig. 6, and vertical section, Fig. 7. When the concrete has set, remove the outside form, pack the dirt firmly around the riser box and provide a sliding lid of sheet iron, as shown, to exclude dirt and hinder the circulation of air.



Figs. 1, 2, 3, 4 and 5.—Cross-Sections of Conduit. Fig. 6.—Lid for Riser Box. Fig. 7.—Vertical Section of a Riser Box. Concrete Conduit for 2-in. Steam Line.

If a leak appears, remove a section of the top with a wedge, draw out the pipe, repair the leak and replace the top with new concrete. A length of 25 ft. of pipe can be drawn out and replaced with no trouble. This cannot be done with wood, log, tile, wooden box, or most other kinds of conduit on account of the inside supports. Many hundred feet of this kind of conduit have been installed and no trace of cracks has been found at any of the places that were uncovered to examine the concrete.

THE WET FILTRATION OF COOLING AIR FOR ELECTRICAL MACHINERY.

THE application of air, cleaned by what is now generally known as wet filtration, to the cooling of electrical machinery is a comparatively recent innovation, and the installations of this type are as yet few in number. Owing to the rapidly increasing number of turbine-driven generators requiring large and constant volumes of ventilating air, engineers are much interested in the method, and are discussing its possibilities. While on the one hand some are favorably disposed towards the new practice, the majority, frankly doubtful, prefer to await the verdict of time in those cases where it is in use before coming to a final decision. As the time is opportune, we reproduce the following remarks on the subject contained in an article by Mr. D. A. Hackett in the Electrical Review, dealing with a few of the technical aspects, with the view of stimulating the discussion of the practice.

The process of wet filtration may be briefly described as the bringing of the air which is to be cleaned into intimate contact with water in the form of a very finely divided spray. The air may thus be said to be actually washed, for as the particles form nuclei for the formation of drops, they are removed from the air current passing through the apparatus, both by their rate of fall being rendered greater and by the interposition, in the path of the spray-laden air, of specially shaped baffles from which the air issues clean and without trace of suspended moisture. In addition to the removal of dust particles, the no less objectionable acids, or acid-forming gases, are removed, being absorbed by the water.

The first question that arises is whether it is possible for the water particles to be carried over from the filter by the moving air. It is simply a matter of installing apparatus capable of dealing with the quantity of air required, and there is little doubt that manufacturers of this class of plant would be able to fulfil guarantees of the absolute absence of every trace of suspended moisture in the discharge from the filter.

The air leaving the apparatus is humid, and the greatest amount of discussion in connection with this subject has been devoted to the possibilities attaching to this condition. The insulation resistance of material is reduced by the presence of moisture in it, and considering only the humidity of the filtered air, it might be unsafe, to say the least, to pass it in its practically saturated condition through a machine. This view may be considered from several aspects. It must be remembered that the climate of this country is such, that electrical machines are frequently subjected (more often of course in winter) to atmospheric conditions approximating to 100 per cent. humidity for long periods. This is the case particularly where the machines are of the type requiring forced ventilation, and it is ordinary practice, where the environment is suitable, that is, where the atmosphere remains clean, to pass the air through machines unfiltered, without damage resulting to the insulation. In foggy weather the air is supersaturated and contains particles of moisture, but there is no record of machines having broken down due to the reduction of the insulation resistance at such times, nor is any provision ever made to reduce the quantity of moisture in the event of a fog or unusually humid atmospheric conditions. Finally, machines are insulated for use under ordinary conditions of surrounding air; in practice manufacturers' tests are assumed to be made without any special precautions with regard to humidity, and in very many cases it is even specified that the apparatus under consideration should remain in the shops for some days previous to testing subjected to ordinary atmospheric conditions. It would appear then, that the factor of safety of insulation as applied to electrical machines in general would cover such of these as are ventilated by wet-filtered air.

It might be of interest to examine the effect of the passage of the air to and through the machine, on the air itself. Let it be assumed that the filtered air is saturated, that is, that its humidity is 100 per cent. (actually it does not always reach this, the average condition being more nearly represented by 95 per cent.). The air leaving the filter passes to the machine but before coming into contact with the windings, it has to encounter resistance in the form of ducts and bends, and has also to be forced through the machine by some form of fan. In this process energy is expended, the air temperature is raised, and the humidity thereby reduced. It may seem that this effect is slight, but in the first place it requires a comparatively small amount of energy to raise the temperature of a cubic foot of air through one degree (0.575 watts per cubic foot per minute), and for a given moisture content the humidity of a given weight of air decreases rapidly as its temperature rises.

If air at 19.5 degrees C. and 100 per cent. humidity at normal atmospheric pressure, have its temperature raised one and a half degrees, the humidity drops to 90 per cent. If an actual case be taken, and assuming 65 per cent. as an average figure for the efficiency of the external fan supplying air to the machine, calculation shows that the losses in the fan and ducts produce an increase in temperature of about three degrees before the air comes in contact with the windings. The resulting humidity in this case with 100 per cent. leaving the filter is 79 per cent., which is below the average for winter atmospheric conditions in this climate.

It has also been pointed out that the air around a central station, by reason of the water vapor liberated in various operations, has, as a rule, a large amount of suspended moisture present against which no special precautions are taken.

The effect of the heating of the machine itself must be considered. An examination of the heating curve shows a sharp and immediate rise in temperature after putting on load. This should act in the direction of preventing an undue absorption of moisture by the windings, should the humidity be high. It is also worthy of consideration to note that in a generating station, due to the radiation from steam pipes, engines and generators, the air temperature is higher than the external air, and, as a result, the windings of a machine, when put on load, are already several degrees higher than the cooling air, and therefore initially more likely to resist the condensation of moisture in them. This fact, taken in conjunction with the rapid rise in temperature referred to previously, and the increase in temperature due to work done in moving the air, tends towards the reduction of the percentage of humidity, and therefore to the original condition of the air as regards moisture previous to filtration.

It is claimed that the air is cooled as well as cleaned by the process of wet filtration, and as this tends in the direction of a lower maximum temperature, it is desirable to form some idea as to the amount of the reduction in air temperature and the effect of the increased moisture content on the cooling qualities of the air, that is, practically speaking, on its specific heat. If air be taken at atmospheric conditions of temperature, pressure and hu-

midity, and caused to take up water vapor in such an apparatus as the filter under discussion, the air will be cooled owing to the heat absorbed in the evaporation of the water. It is correct to assume that the quantity of heat lost by the air is equal to that absorbed by the water during evaporation. From this consideration the reduction in temperature due to air taking up various quantities of moisture can be calculated, and from hygrometric charts it is a simple matter to obtain the amount of vapor present at the assumed condition (for air leaving the filter) of 100 per cent. humidity at any temperature. The temperature to which air at any other temperature and humidity falls when saturated in this manner, can be obtained with reasonable accuracy. The air temperature will not be reduced quite to the wet-bulb temperature corresponding to the atmospheric conditions, but to a temperature slightly higher, due to the increase of the moisture content consequent on the passage through the filter. A concrete example will make evident the extent of the cooling effect.

If air at 13.9 degrees C. and 81 per cent. humidity, corresponding to average summer conditions, be treated in a wet filter so that it emerges at 100 per cent. humidity, the resulting air temperature is 12 degrees C. The wet-bulb temperature corresponding to the original conditions is 11.75 degrees C. The cooling effect is due mainly to the latent heat absorbed by the water in evaporating, and it does not seem feasible except possibly in special cases still further to reduce the temperature materially by the addition of refrigerating plant, cooling the water supplying the sprays in the filter. It is doubtful if much advantage can be gained in this way unless some highly efficient, compact refrigerator capable of operating without supervision, can be found.

With regard to alteration in cooling qualities, an investigation of the change in specific heat and density, for the average conditions given, shows a 0.2 per cent. increase in specific heat, and an increase in density of, approximately, the same amount, so that there is a slight advantage in these respects also.

Summing up, it would seem that there is a fairly good case for the installation of wet air-filtration apparatus from the purely technical aspect. It undoubtedly produces clean air, the advantages of which it is not necessary to dwell upon, and whilst the reduction in temperature may not, generally, be great, the air is certainly cooler after filtration. With regard to the danger of breakdown, it would be of interest if some experiments were carried out under actual conditions to discover if any material alteration in insulation resistance does occur, and in this connection experience might be gained at first on low-voltage machines, where the risk of breakdown is less. It is outside the scope of this article to discuss the costs of such installations, the different types, or comparative figures for upkeep, but it might be urged that the publication of such particulars would be of the greatest interest to electrical engineers in general at the present time.

The business of the Tungstolier Company of Canada has been taken over by the Canadian General Electric Co., Limited.

It has been stated at Philadelphia that part of the pig iron which R. D. Wood and Company will cast into pipe in their 40,000-ton Italian aqueduct contract, will be brought there from Canada. This particular iron will come from Sydney, Nova Scotia. About 15,000 tons is understood to have been contracted for to be delivered at docks at Philadelphia at about $13.50 per ton.

CONSTRUCTION OF A JETTY OF SPECIAL DESIGN.

By V. J. Elmont, B.Sc., A.M.Can.Soc.C.E.

On the west coast of the Danish peninsula, Jutland, there has been completed a jetty, built of concrete blocks. It is worthy of record on account of the magnitude of the blocks, which are up to 102 tons in weight, its special design, and the difficulties which had to be met during construction owing to the heavy seas on that coast.

The jetty runs 1,000 ft. into the sea and has a width at the top of 20½ ft.; the maximum depth of water is

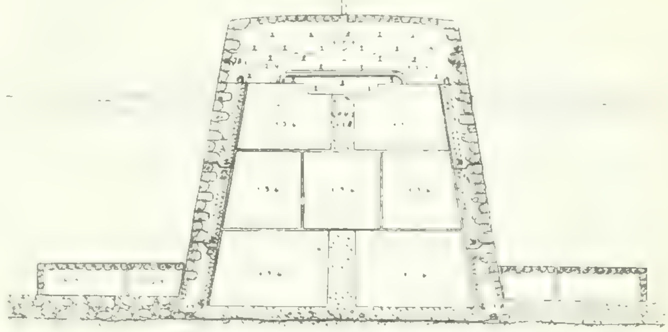

Fig. 1.—Cross-section of Jetty.

20 ft. The masonry of the jetty does not begin directly at the shore, but is connected with it by a bridge. The prevailing current conditions made it necessary to provide a free space between the jetty and the shore in order to prevent deposition along the jetty of sand and gravel carried by the coastwise current.

The cross-section in Fig. 1 shows the method followed in the design. The outside walls are composed of three 16-ft. long granite-faced concrete shells on top of each other, the operation of placing them being effected by means of a Titan crane of 110-ton capacity. The bottom

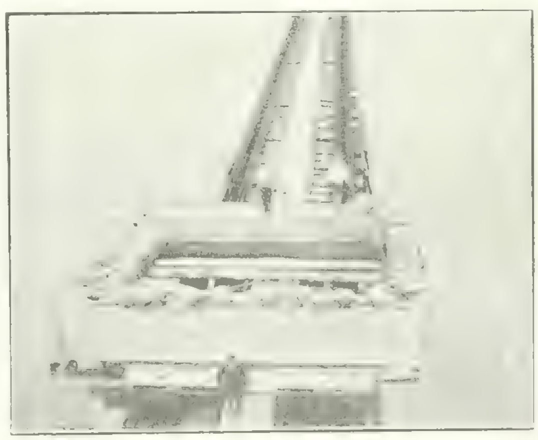

Fig. 2.—Showing a Section on Way to Site.

shell (one of them is seen under transportation in Fig. 2) was placed on the uneven ground, when the loose material covering it had been removed with a grab bucket, attached to the crane (Fig. 3). The bottom shell being in position, a sheet of cloth, connected to the sides of the shell, as indicated in Fig. 2, was spread over the base (shown also in the cross-section). On this was placed a layer of gravel, grouted with cement after being levelled

off. In Fig. 2 will also be noted a thick strand of oakum used to ensure tightness between each pair of shells, and the concrete and cement bags on which the shell was set, thus making a close joint between the base and the shell. The box formed by each set of three shells is filled with concrete blocks and the space left between these with a rich mixture of concrete.

It was originally intended to build the superstructure (granite and concrete masonry) *in situ*, but it was afterwards deemed preferable to adopt block work for a part of it. The superstructure for each section, formed by three shells, was completed by two concrete and granite facing blocks of an average width of 5 ft.; the space between them was filled with 1:2:4 concrete, reinforced with rails running lengthwise in the jetty.

Fig. 3.—110-ton Crane Used in Placing Sections and Blocks.

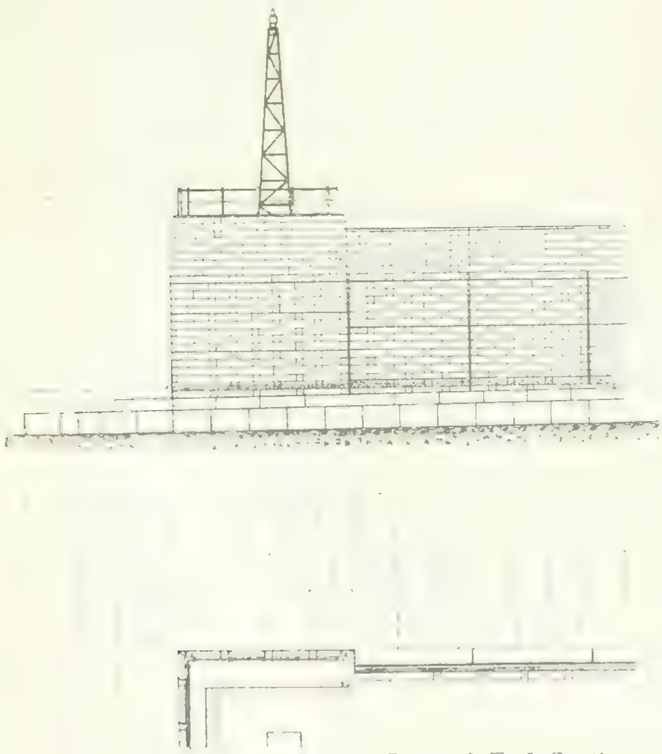

Fig. 4.—Elevation and Half Plan of End Section.

These blocks have the same dimension in the length of the jetty as the shells on which they rest. A continuous expansion joint is thereby formed from the base to the top of the jetty, provision being made for a joint in the concrete forming the centre part of the superstructure.

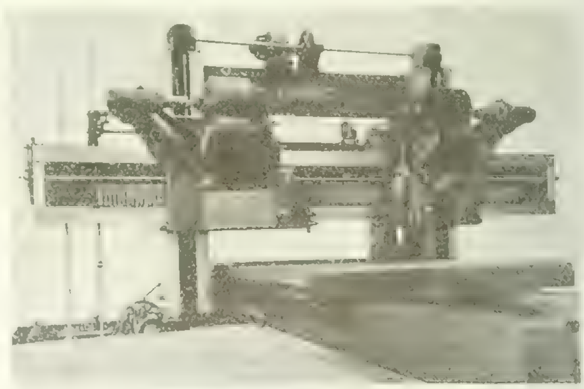
The footing of the jetty is secured against scour by means of two granite-faced concrete blocks on each side, having a total width of 13 ft. At the head of the jetty these blocks are 21 ft. wide, made up of three rows, that nearest to the jetty weighing from 15 to 20 tons, the others 8 and 9 tons respectively.

The head of the jetty (shown in plan and elevation in Fig. 4) was built up of four shells, differing somewhat from those already mentioned. They have vertical sides and are 24 ft. long and 28 ft. wide. Their weight varies from 84 to 102 tons. The total weight of the head section, when filled with concrete blocks, is 1,020 tons, while the one adjacent weighs 638 tons. By the aid of the superstructure these two sections are combined to form one mass, having a weight of 2,035 tons.

SPECIAL PLANER OF INTERESTING DESIGN.

THE unusual type of planer shown in the illustration was built by the Betts Machine Company, Wilmington, Del., for the Commonwealth Steel Company, Granite City, Ill., after the latter company's special design. It is designed especially to machine the ends of castings running up to 30 feet in length, a proceeding that is impossible with the ordinary type of planer. The cutting tools are therefore arranged so as to move at right angles to the platen, which permits machining the ends of castings of any length as well as other surfaces which cannot be reached with the ordinary planer.

The machine consists essentially of a 10 x 7 x 18 ft. planer of standard construction. The cross rail is, however, special and carries two cutting heads, each of which



Planer for Machining Large Castings.

is driven by a 30-h.p. Westinghouse electric reversing planer-motor.

The two motors are connected together electrically so that if one reaches the end of a stroke before the other, it automatically stops and waits for the other to finish its stroke, when they both reverse together. To obviate the danger of the heads running together, a push-rod is mounted on one which opens the circuit and stops the motors if pressed.

The heads are designed for a cutting speed of 30 ft. per minute and a return speed of 75 ft. per minute, and are guaranteed to take two ½ x ⅛-inch cuts simultaneously in cast steel.

The platen is provided with a power rapid traverse of 20 ft. per minute as well as a power feed. It is driven by a 7½-h.p. motor, while the cross rail is raised and lowered by a similar motor.

LOCAL GOVERNMENT BOARD IN SASKATCHEWAN.

The Third Legislature of Saskatchewan, recently concluded, passed an act to provide for the creation of a Local Government Board, to consist of three members and to exercise broad control over the financial affairs of the municipalities of the province.

Associated with the commissioners for advisory purposes will be two members, appointed annually, one by the organization representing urban municipalities, and the other representing the organization of rural municipalities. The commissioners are not allowed to hold any interest in the securities of Saskatchewan local authorities, or to be members of any company dealing in their securities, nor may they be interested in any work done or contracts let by these authorities. They are also disfranchised both as to municipal and provincial elections.

The term "local authorities" is defined under the Act to mean the council of a city, town, village or rural municipality, the board of trustees of a school district, and the directors of rural telephone companies.

The duties of the board may be briefly summarized as follows: It will have power to inquire into the merits of an application from any of these authorities for permission to raise money by way of debentures or upon security of stock; it may grant or refuse such permission; it may manage sinking funds entrusted to its care; it may supervise the expenditure of money by local authorities; it may demand a detailed statement of the financial standing of local authorities.

All local authorities, excepting cities and towns, desiring to raise money by way of loan, must first make application to the board. Cities and towns must do so prior to the first reading of the money by-law. None of the terms of the existing law as affecting villages and rural municipalities are altered in any way, except that the powers formerly vested in the Minister of Municipal Affairs will in future be vested in the Local Government Board. The same conditions will apply to school districts and rural telephone companies.

The board is given power to investigate the advisability or otherwise of authorizing a loan, and when money is to be borrowed for waterworks or sewerage systems the approval of the Commissioner of Public Health must first be procured, as is provided in the Public Health Act.

The board will have the right to enter upon and inspect any works, require the attendance of any persons whom it sees fit to summon and the production of all desired documents or plans, and in forcing the attendance of witnesses will have the same powers as the Supreme Court.

NO TIME TO TENDER.

Hardly a week elapses but that there is announced some important call for tenders which allows bidders only a week or two for the preparation of their tenders.

"No time to tender" has become a very familiar phrase among Canadian engineering, contracting and manufacturing concerns. Important firms are frequently barred from tendering, simply because of the time element. There are rare occasions when a town or city really requires material or machinery in a hurry. But nine times out of ten, the time allowed bidders could probably be increased by a fortnight, or even a month, without any detriment to the municipality—especially if a little foresight were used and tenders called for promptly

as soon as decision to have the work done had been reached.

Too frequently a council decides one meeting to call for tenders and instructs the city clerk to have tenders in hand by the next council meeting. We have in mind one Canadian municipality that allowed only a couple of weeks for tenders for an engine, and then calmly waited for eighteen months for its delivery; and another municipality that allowed less than two months for the preparation of plans and bids on a job amounting to over a million dollars, and then took over ten weeks to decide which of two bidders should be awarded the contract.

This is a matter of equal importance to buyers and sellers, as bidders often submit figures high enough to protect themselves against all risks, when they are not allowed sufficient time to investigate carefully and to figure accurately and closely.

REPORT ON CITY ARCHITECT'S DEPARTMENT, TORONTO.

Last week Judge Denton's report on the City Architect's Department was made public. It is the result of a lengthy investigation, and careful probing into the affairs of the department has brought out strong vindication of the popular belief that much inefficiency and lack of discipline pervaded the system under which it operated.

During the three months of the inquiry 179 witnesses were examined, 2,614 typewritten pages of evidence taken and 170 exhibits filed and considered.

The report recommends a complete reorganization of the department into a separate branch of civic government to be known as the "Department of Buildings." Its jurisdiction and powers are fully enumerated and show considerable increase over the present system. The head of the department, according to the recommendation in the report, should be called the Superintendent of Buildings.

"He should be the best man available. He should not only have the necessary practical and technical knowledge of the work of the department, but should possess the necessary administrative ability to reorganize and systematize the department and to introduce such reforms as will put an end for all time to come of the conditions at present existing."

The official disclosure of many inconsistencies renders it almost inconceivable that the present condition of affairs will be permitted to continue. Obviously, the department is one of the most important in the administration of civic affairs. There is every need for a superintendent possessing (1) technical ability that may be relied upon for accuracy and dispatch in engineering and architural details; (2) executive ability to reorganize and resystemize the department in order to make it efficient, reliable and up-to-date; (3) practical knowledge of the factors representative of the owner, the engineer, the architect, the contractor, the city and the building by-law; (4) disciplinary powers such that the practices which the present department has tolerated will immediately, without modification, cease.

Further, the responsibilities of this office are such as to require a man who will rigidly adhere to the belief that his is a department that cannot permit an invasion of foreign forces in the carrying out of its duties for the protection of life and property.

LETTERS TO THE EDITOR.

Artesian Water in Manitoba.

Sir,—For many years, in fact almost ever since Winnipeg has been a city, it has depended for its water supply on wells sunk through the impervious layer of boulder clay which underlies the city into a bed of porous limestone, from which water rises in great abundance. From these wells the city has been able to obtain a plentiful supply of water which, while containing a slight amount of mineral matter, is absolutely free from any hurtful bacteria, or from organic germs of any kind.

Probably no city on the continent has such a secure supply of sterile water as Winnipeg, but the city council has evidently decided that the supply is not sufficient and cannot be sufficiently increased to keep pace with the rapid growth of the population, and therefore it is said to be making arrangements to bring water from Lake of the Woods in an open aqueduct, and to take all the chances of the introduction of impurities which such a method of obtaining water necessarily entails.

Before stepping down from a safe and sterile water supply to one which may not always be safe and pure, it would be worth while to make every possible endeavor to increase the flow of pure water from the present wells.

The porous limestone into which these wells are sunk, and from which the water rises, extends to the north and west beneath a layer of boulder clay, and rises to the surface in a number of places in the country between lakes Winnipeg and Manitoba at elevations varying from about fifty to one hundred and fifty feet above the level of the prairie at Winnipeg. The rain falls on these bare rocky areas, as well as on the adjoining clay-covered country, but instead of flowing away in rills and streams, as it does on the clay-covered country, it at once sinks into the porous limestone and flows through this limestone southward and eastward until it finally reaches the surface either in the large springs north of Winnipeg or through the wells at the city of Winnipeg itself. The quantity that flows from these springs and wells is therefore largely limited to the amount of the rain-fall on those portions of the surface where the porous limestone is uncovered. Where it is covered, as it is in many places, most of the water derived from the rain either stands in small lakes and evaporates from the surface, or drains off towards Lake Winnipeg or Lake Manitoba by the many little streams which unwater the country.

The underlying porous limestone through which the water percolates on its way from the exposed areas northwest of Winnipeg to the wells in Winnipeg is a magnificent natural filter which is protected from contaminating influences throughout the populated parts of Manitoba by a thick covering of impervious boulder clay. No other city on the continent is provided by nature with such a filter, and no city could afford to duplicate it. When nature has provided such a magnificently covered filter as this great bed of porous limestone to clarify and purify the water used by its people, those people cannot afford, with due regard to their own health and welfare, to disregard it.

It may be that the supply of water, obtained from the wells sunk into this natural filter basin, is insufficient for a city of the size to which Winnipeg will certainly grow, but it would be well to determine, if the fact has not yet been determined, whether such insufficient supply is the fault of the inefficiency of the natural filter, or whether, as is much more likely to be the case, it may

be caused by an inadequate supply of water to the bed of porous limestone which forms the filter.

If the supply of water available from the wells is inadequate could it not be increased? Could not the lakes and streams which now drain the water from the country to the northwest be diverted into this great natural filter, or even would it not be possible to divert some of the water of Lake Manitoba itself into it?

These questions are worth deciding before the present methods of obtaining pure water from artesian wells is abandoned.

J. B. TYRRELL,
Consulting Geological Engineer.

Toronto, March 31st, 1914.

Jointing of Water and Gas Mains.

Sir,—I notice a letter in your issue of the 26th inst., by "Hydraulic Engineer," on "Jointing of Water and Gas Mains."

In regard to his remarks on steel pipe my own experience may be of interest.

I have laid for the Montreal Water and Power Company something over 8 miles of steel main in 60-in., 48-in., 36-in. and 30-in. diameter, and from 7/16 in. to 5/16 in. thickness for working pressures ranging from 200 to 65 lbs. per square inch.

The first mile of 36-in. was laid with a single rivetted butt strap joint. This was found to be a nuisance and expensive to lay as the joint made at the mill (the strap being rivetted to each 30-ft. length of pipe) had to be completely gone over in the field to render tight.

The remaining 6 miles of this line was obtained in tapered pipe with a total taper in 30 ft. equal, approximately, to twice the thickness of the plate. A single row of holes was shop drilled at the end of each length and a single rivetted lap joint, made entirely in the field, thus obtained. This has proved an absolutely satisfactory joint and no trouble has been experienced even with pressures up to 250 lbs.

The high pressure of 250 lbs. has been recorded due to "surging" after a sudden and accidental stoppage of the pumps.

At one point in the main a crossing of the Lachine Canal occurs. This was made in flanged steel pipe, the flanges being steel angles. Experience has shown this to be a weak and unsatisfactory joint, difficult to get tight.

I have not had experience with the lead yarn spigot or faucet joint in steel pipe, but would doubt its durability at high pressures and in large sizes.

F. H. PITCHER,
General Manager and Chief Engineer,
Montreal Water and Power Company.

Montreal, March 31st, 1914.

* * * *

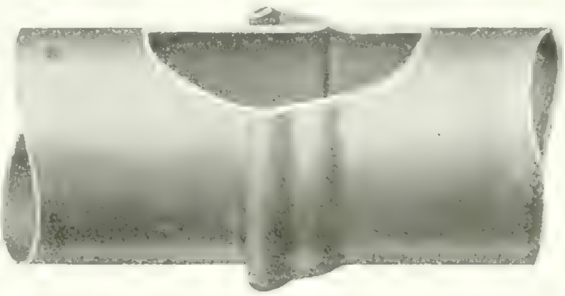
"Jointing of Water and Gas Mains."

Sir,—It is unfortunate that your correspondent "Hydraulic Engineer" did not take a little trouble to become acquainted with the actual facts of the case before making such statements as appeared in his letter in your March 26th issue. Certain of these statements are so misleading that it may interest you to have the exact position placed before you.

Your correspondent states that the process of oxy-acetylene welding is so expensive and difficult to perform, that it can be discarded as not practicable. To the contrary, the new process of welding joints is an acknowledged success, and it may interest your readers to know that orders and repeat orders have been received from about thirty gas and water companies in Great Britain, where, if anywhere, the engineer is most conservative in his ideas. To give one special instance: The City of Birmingham has installed about three miles of 9-inch pipe with this patent joint for gas work, and the probabilities are that many repeat orders will be secured from the same source.

The article in your recent issue on this new process of welding joints gave an account of the effect of expansion, and perhaps your correspondent will be good enough to read that over, so as to improve his ideas on the subject.

Another point to which exception can be taken in your correspondent's remarks is the type of sockets which he advocates for pipe lines. The consensus of opinion of engineers is strongly in favor of the following type:



The reinforced bell end removes any danger of splitting of the pipes during the caulking operation, and the turned-up spigot makes it impossible to draw the pipes apart after they are joined with lead and yarn. There is, also, a very deep groove in the socket for lead, which is a feature wanting in the special type of sockets shown in the sketches in your article of last week. The extensive mileages of pipes with this type of socket now in use can verify its popularity with engineers.

It is hoped that the above remarks will now make matters quite clear to your correspondent as they can be proved by actual fact.

A. HUTCHISON.

Montreal, March 30, 1914.

NEW SURVEYING ACT FOR SASKATCHEWAN.

The old Land Surveyors Act has given place in Saskatchewan to an act passed at the recent meeting of the Legislature of that province. The new legislation differs from the old principally in that the examination of all candidates desirous of obtaining a commission as an S.L.S. is now placed entirely in the hands of the Saskatchewan Land Surveyors' Association. This association is now placed on the same basis, and will receive the same recognition as other professional associations. It is now necessary for Saskatchewan land surveyors desiring to practise in the province to conform to the requirements of the association respecting registration.

The recently-issued report [illegible] Vancouver gives the following [illegible] the city at the close of the year:—Permanent street pavements, 51.453 miles; permanent lane pavements, 3.213 miles; streets, rocked, 146.556 miles; lanes, rocked, 25.050 miles; cement concrete sidewalks, 202.184 miles; sewers, 170.01 miles; water mains, 298.84 miles.

HYDRO-ELECTRIC POWER DEVELOPMENT AT WASDELL'S FALLS.

THE sixth annual report of the Hydro-Electric Power Commission of Ontario contains a section devoted to water-power investigations that are being carried out by the engineers of the Commission on a number of rivers throughout the province. Among them, the one farthest advanced at the present time is

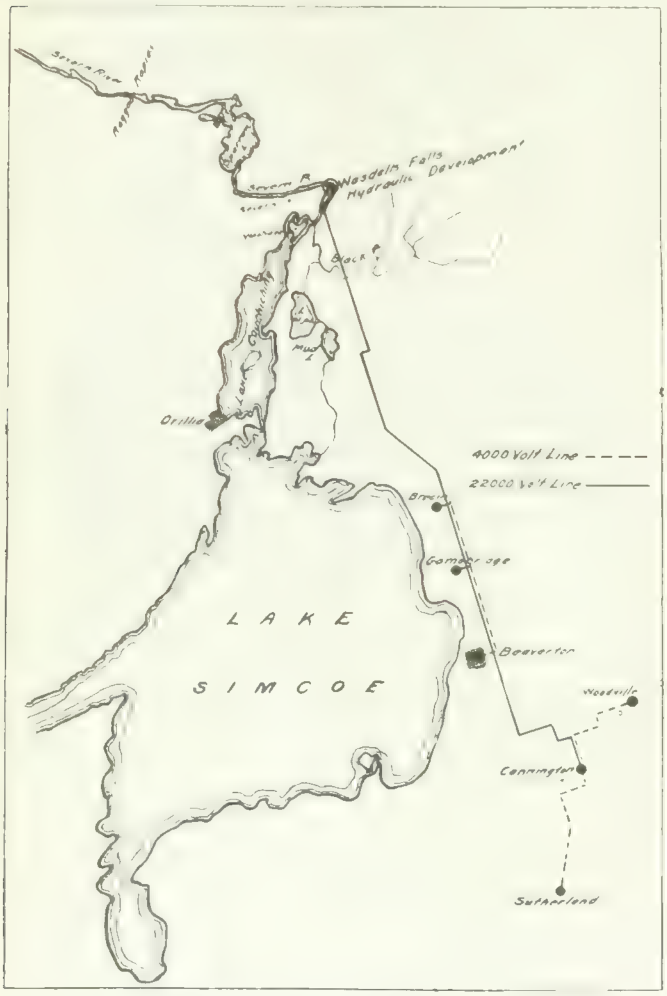


Fig. 1—Wasdell's Falls Development, showing Location and Projected Transmission Lines.

the development at Wasdell's Falls on the Severn River. There power studies are all carried out under the direction of Mr. F. A. Gaby, Chief Engineer of the Commission; by Mr. H. G. Acres, hydraulic engineer, and Mr. T. H. Hogg, assistant hydraulic engineer of the Commission. The information contained in their reports on the Wasdell's Falls project includes the following:—

The drainage area of the Severn River above the power site at Wasdell's Falls is about 2,080 sq. mi. About 700 sq. mi. of this is included in the watershed of the Black River, which joins the Severn about midway between Wasdell's Falls and the outlet of Lake Simcoe at Washago, as shown in Fig. 1. The maximum flow at Wasdell's Falls, as so far ascertained from gauge records and discharge measurements, is 9,000 sec-ft., or 4.32 sec.-ft. per sq. mi. of watershed. Under conditions that will obtain in the future, it is probable that the maximum discharge will never exceed 5 sec.-ft. per sq. mi., this low figure being due mainly to the potent regulating influence of Lake Simcoe, and to a small extent to the smaller lakes in the upper watershed.

The extreme minimum flow, during the period that the river has been under observation by the Commission, was 260 sec.-ft., or 125 sec.-ft. per sq. mi. The average flow for the period from October 1, 1912, to November 1, 1913, was 2,850 sec.-ft., or 1.37 sec.-ft. per sq. mi. This was one of the driest periods on record, so that the above is a fair indication of the minimum value of mean annual flow. On this basis the ratio of maximum to average flow is approximately as 3 to 1.

The area of Lake Simcoe is about 297 sq. mi., and when the Severn section of the Trent Canal is constructed the lake will be completely controlled by regulating dams at Washago. An annual storage draft of 18 in. may then reasonably be considered available, in which event the volume of available storage will be 12,420 million cu. ft., or 284,500 ac. ft.

The plant at Wasdell's Falls is designed for a peak capacity of 1,200 h.p. The Trent Canal works are designed to hold the tail-water level at El. 698, and with the proposed head-water level of El. 712.5, about 950 sec.-ft. of flow will be required to carry the peak load. On a 75% power factor basis the average flow will, therefore, require to be 700 sec.-ft.

The available volume of storage will provide the required average flow for 207 days in each year. Leaving an ample margin for unavoidable waste and inefficiency of operation, it is, therefore, evident that a sufficient supply of water may be anticipated at all times.

The power site at Wasdell's Falls is the only source of power from which the municipalities of Woodville, Sunderland, Cannington, Beaverton, and Brechin, may be economically served. These municipalities, in November, 1912, passed by-laws and subsequently contracted with the Commission for the supply of 625 h.p. Detailed investigations were immediately instituted, and estimates covering the cost of delivered power were submitted to the municipalities and found acceptable. The Commission, acting under authority of the Power Act, obtained an Order-in-Council covering the purchase of the site and the development of power at Wasdell's Falls, and early in 1913, work was begun upon plans and

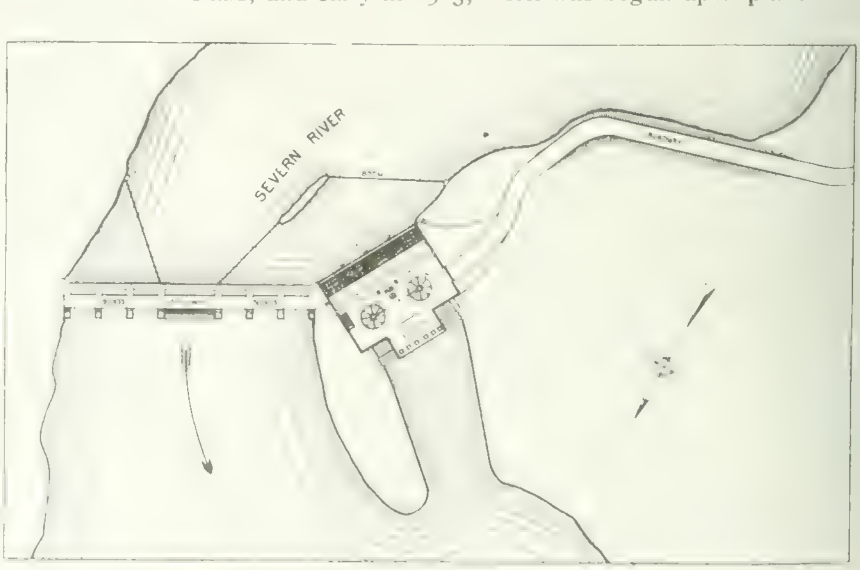

Fig. 2—General Arrangement of Wasdell's Falls Power Plant.

specifications for the hydraulic portion of the plant. Fig. 2 shows the general layout of the development, and Fig. 3 is a cross-section illustrating the power-house arrangement.

Tenders for the construction of the dam and power-house and for the hydraulic equipment were called for in

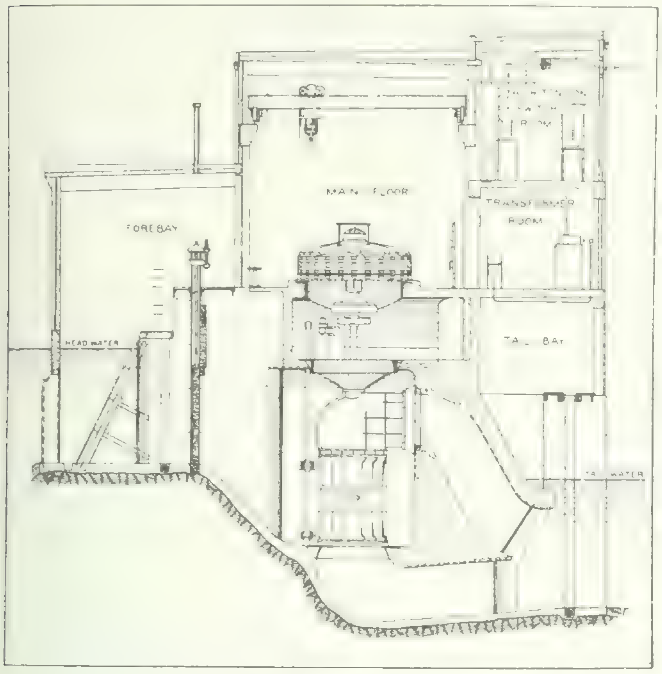

Fig. 3.—Cross-section of Power-house at Wasdell's Falls.

June, 1913. The various contracts awarded were dam and power-house, Galbraith & Cate, Montreal; turbines, Boving Company of Canada, Limited, Toronto; stop-log winch and head-gate lifting mechanism, Wm. Kennedy & Sons, Owen Sound; crane, W. D. Beath & Son, Limited, Toronto.

As regards the dam and power-house contract, the greater portion of the month of July was taken up by

Fig. 4.—Erection of Power Plant, Piers Completed.

the contractor in the purchase of plant and the installation of same at the site of work, and it was not until the middle of August that construction work was well under way. Since that time, however, good progress has been made, and there is every reason to anticipate that under the worst conditions likely to obtain the work will be beyond the reach of the high water of 1914, and with reasonable working conditions the entire works will be completed in May, 1914. Fig. 4 is a progress view of the main dam, showing the piers completed.

The contracts entered into with the above municipalities do not by any means represent the extent of the market which the Wasdell's Falls development will serve. It is confidently expected that a large rural load will be developed in the agricultural townships of Mara, Thorah and Brock, and that the demands of these townships will practically double the present contracted load.

Apart from the low head, the topographical conditions at Wasdell's Falls are favorable for development purposes, and the value of the site as a source of power will be doubled when the dams incidental to the Trent Canal construction are built across the outlets of Lake Simcoe at Washago, which is less than three miles above the plant, making the immense storage capacity of Lake Simcoe during available low-water periods.

FOREST PRODUCTS' LABORATORIES EXPAND.

The Forest Products' Laboratories, instituted last autumn by the Dominion Government in conjunction with McGill University, contemplates the enlargement of the department, and has applied to the university for the use of another building. The McGill authorities are quite agreeable provided that the Forest Products' Service is able to repair the building in such a way as to make it a safe place for the headquarters of the new department, until the extensive plans are carried into effect when the various exhibits and staff of the service would then be housed in one of the new buildings which may be erected.

The trouble with the building is that it is sinking in the same manner as the McGill Union buildng sank some time ago. At present it is propped up with large wooden beams and as it is erected either on the bed of the old Molson Creek or on the shifting clay or sand that has been found to be very prevalent in this locality, it would be a big job to dig down to rock bottom and put a new foundation under the building.

PORTABLE METAL BUILDINGS.

Metal buildings have always been much better than wood structures for contractors on railroad and other engineering work, owing to safety, convenience and other favorable factors which their use assures. The new all-steel and metal-clad buildings now being made by the Pedlar People of Oshawa, Ont., make it possible for contractors and others to equip themselves with metal buildings with the maximum of convenience and ease of erection. They are made of Toncan metal, and are portable. They are very handy, and are especially in demand for railway work, as tool houses, shelters, oil stations, freight and wharf sheds, lamp and storage houses, etc. A very favorable feature of these buildings is that they can be added to in 8-ft. lengths at any time. They resist fire, corrosion, thieves, vermin, etc., with reliability and assurance.

QUICK COMPUTATION OF WEIGHTS OF BARS.

To find the weight of square or flat iron or steel bars, "Iron Age" suggest's multiplying the sectional area of the bar by 10/3, which will give the weight in pounds per lineal foot. Add 2 per cent for steel. For example, in the case of an iron bar 1½ x ½ inches:—

3/2 × ½ × 10/3 = 5/2 or 2½ lb. per lineal foot.

For steel, add 5/100 = 2.55 lb. per lineal foot.

In the case of round steel bars, to find the weight per lineal foot, divide the square of the number of quarters of an inch in diameter by 6. For example, in the case of a steel bar ¾ inch in diameter:—

3 squared (three being 3 quarters) 9 divided by 6 = 1½ lb. per lineal foot.

SOME GOOD ROADS, THEIR CONSTRUCTION AND MAINTENANCE.

By Robert C. Muir, C.E.,
Mackenzie, Mann and Company, Toronto.

ONE of the chief requirements of our advanced civilization is good roads. This is proved by the growing demand for them. The excellence of the Roman roads still existing in various parts of Britain is direct proof of the high state of civilization to which the ancient Romans had attained, and it is admitted that no more reliable evidence can be given as to the condition of a people than that evinced by the quality of their roads, experience teaching that social, industrial and commercial development depend largely upon them.

Everyone interested in the question realizes that manufacturers, merchants and farmers save thousands of dollars through being able to haul their products to markets over an improved highway. This, the author considers the best reason for spending money on good roads.

The chief factor at the present moment is, Where is the money to come from to build and maintain good roads?

For reference the author will here explain the method employed by the Imperial Road Board of Great Britain for raising and apportioning money.

Imperial Road Board of Great Britain.—It was constituted under the Development and Road Improvement Funds Act, 1909.

The money derived from motor spirit duties and motor car license duties, imposed by the Finance Act (1909-10) is as follows:

Motor spirit excise duty of 6c. per gallon.

Manufacturer's license $4.85	Additional excise
Dealer's license $4.85	duty of $1.25 each.

Rates of Duties on Motor Cars.

Motor cycles and bicycles	$ 4.85
Motor cars not exceeding 6½ h.p.	9.70
Motor cars exceeding 6½ h.p. but not exceeding 12 h.p.	14.55
Motor cars exceeding 12 h.p. but not exceeding 16 h.p.	19.40
Motor cars exceeding 16 h.p. but not exceeding 26 h.p.	29.10
Motor cars exceeding 26 h.p. but not exceeding 33 h.p.	38.80
Motor cars exceeding 33 h.p. but not exceeding 40 h.p.	48.50
Motor cars exceeding 40 h.p. but not exceeding 60 h.p.	101.85
Motor cars exceeding 60 h.p.	203.70

The above-mentioned sums go to Road Board less cost of collection. The sum credited to the Road Board improvement fund for years 1909-10 and 1910-11 aggregated $5,806,720.

In 1910 the Road Board issued a circular as follows: "For guidance of highway authorities who contemplate making application for grants, the Board desires it to be understood that, at the outset, applications should be confined to those of the most important and urgent nature, and that special consideration will be given to those in connection with proposals dealing with:

(1) Reconstruction of important roads, the condition of which is exceptionally bad and cannot be improved without reconstruction.

(2) Widening of important roads which are dangerously narrow.

(3) Surfacing with granite, basalt, or other suitable material treated with tar or other bituminous compound by some approved method, main roads or important district roads which already have adequate foundations, especially those in or just beyond the fringe of large towns, which have to carry a heavy traffic without aid from rates of the towns served by the roads.

(4) Opening out dangerous corners and alteration of dangerous curves.

(5) Alteration, where possible at reasonable cost, of steep gradients.

(6) Strengthening or reconstruction of weak bridges, which seriously limit the use for commercial transport of roads of first class importance.

(7) Construction of new by-pass roads to avoid villages or main roads or important district roads where the conditions are exceptionally dangerous.

(8) Acquisition in urgent cases where building is imminent of vacant land required for future widening of roads, especially in urban or suburban areas.

Allocation of Grant.—The Board goes upon the principle of paying 75% of any approved scheme. First of all they must be satisfied that any proposed scheme will be beneficial to the through users of the road, and secondly, to the local authority charged with its upkeep.

This 75% is of the portion of cost which is extra over the ordinary yearly upkeep, that is to say, the average yearly upkeep is deduced from the total estimate of the scheme; then the Board pay 75% of the remainder.

This is the general principle with all county authorities, but the Board is not so generous with municipalities, where a grant of 25 to 35% is only occasionally allowed.

Specifications of Road Board.—The Board gives specifications for surface tarring, tar macadam, pitch grouted macadam, and No. 1 and No. 2 tars.

Tar Macadam Specification.—(1) Roads must have proper foundation.

(2) Thickness of surface should be ascertained by opening roadway.

(3) Thickness of tar macadam when finished should be from 2 to 3 in.

(4) Hard subsoils should have at least 6 in. of road crust foundation, and clay subsoils at least 11 in.

(5) Cross fall should be 1 in 32.

(6) The aggregate of the tar macadam should be of approved stone, at least 60% broken to 2½ in., 30%, 2½ to 1¼ in., and 10%, ¾ to ½ in., the last-mentioned to be kept separate and used as top dressing.

(7) The stone to be dried before coating with tar.

(8) Tar to be in accordance with Board's specifications Nos. 1 or 2.

(9) The quantity of tar to be from 9 to 12 gallons per ton.

(10) To be rolled smooth.

(11) Paint surface with tar after road has been open to traffic for some weeks.

(12) Surface to be gritted with ½ in. chippings.

Specification for Tar No. 1.—Tar should be treated to a temperature of 220° to 240° F. It should be derived from the carbonization of bituminous coal.

The specific gravity at 15° C. should be 1.19 or may vary from 1.16 to 1.22.

It shall not contain more than 1% of water, which water shall not contain more than 5 gr. of ammonia per gal. of tar.

Specification for Tar No. 2.—Tar should be heated to 260° to 280° F. It should be derived from the carbonization of bituminous coal. Specific gravity at 15° C. should be 1.21 or may vary from 1.18 to 1.24. The tar shall be free from water and shall yield no distillate below 140° C., nor more than 3% of distillate up to 220° C. Between 140° and 300° C. it shall yield not less than 15%, nor more than 21% of the weight of the tar.

At this point it might be convenient to mention that in Great Britain there are over 231,000 miles of roads, some of which, it is said, are the finest in the world, and for which the cost of upkeep in 1892 was $42,500,000. But last year (1913) the cost of upkeep was over $90,000,000. The number of motor cars is estimated at 240,000.

Various Kinds of Roads.—The engineer's problem of to-day is how to build and maintain good roads.

Macadam Roads.—These, when properly built and maintained, form the safest, pleasantest and cheapest road surface known for suburban streets and country roads.

The Telford and Macadam methods have given best results in a rather wet locality where the water has aided in binding the materials, and its removal by drainage of the roadbed and surface was the most important point in the maintaining of a good road. The said methods carried out in a locality having little or no rain, drainage is unimportant, and the preserving of a well-bonded surface is of the greatest importance. This bonding may be secured with a bituminous binder.

Points to be observed in construction of macadamized roads:

(1) The removal from roadbed of all vegetable matter.

(2) Subsurface drainage.

(3) Use of the very best material afforded by locality, and if traffic warrants it, the importation of suitable material.

(4) Classification of stone, 2½ in. down ½ in. chippings.

(5) Complete exclusion of loam and clay from stones.

(6) Use of stone dust and screenings, same quality of stone used to fill interstices.

(7) Thorough consolidation of stone by using a 10-ton steam roller.

Quality of Stone.—The material used for this class of road must naturally vary according to locality. Local stone, owing to cost of haulage, must generally be used. Should the traffic be excessive it will be found more economical to procure a superior stone, even at a greater cost than the local stone, in all cases where traffic is great, the best material obtainable is the most economical.

The qualities required are toughness and hardness—ability to resist the breaking up action of the weather.

A well-made and formed limestone road will be more impervious to wet than any other, having a detritus which acts like mortar in binding stones together and will not break up so soon in dry weather. Hardness without toughness is of no use, as a stone can be hard, yet so brittle as to be crushed to powder under a heavy load, when a stone not so hard but tough will be uninjured.

The author advocates the rolling of foundation and of each coat or layer of stone, the finished surface to be of chippings and dust of same quality of stone used, this to be watered and rolled until consolidated.

Watering.—Water expedites the consolidation, lessens crushing under the roller, and aids the filling of interstices with binder. The spray should be fine, a sprinkler being used, and not thrown on in quantity or by use of hose. Excessive watering tends to soften foundation and great care should be taken in applying it.

Rolling.—A steam-roller has proved to be the most economical. There is no rutting by wheels of vehicles, or holes wherein water can lodge; resistance is reduced to a minimum, saving wear and tear of horses and vehicles, and comfort of people using the roads. Roads should be made for the traffic and not by it. The use of a 10-ton steam roller for all purposes except asphalt construction, is strongly advocated.

Breaking of Stone.—Stone should be broken by hand, a practice which finds favor with many engineers in Britain. With this method of breaking, stones are more uniform in size, have sharper edges, are not flaky with rounded edges, and are therefore better for compacting. The installation of the machine breaker or crusher has effected a great saving in cost and also increased the output considerably.

In Canada, where labor is very expensive, the breaking of stone by crusher is undoubtedly the best method. The hand-breaking method, though the best, is very expensive. The wear and tear of crusher and also the initial cost are very great.

To be a paying factor, the crusher must be kept in almost constant use. Great care must be taken in feeding and must be placed so as to reduce to a minimum the cost of handling the broken and unbroken stone.

In many places a fixed plant is used for crushing, the stone being brought to the crusher. The haulage in this case may be very great, which increases the cost considerably. It is, therefore, generally more economical to take the crusher to the stone, and this is done by having a crusher of portable type and using the steam-roller to haul it.

Surfacing of Macadam Roads.—The methods employed in re-surfacing are:

(1) The surface is cleared from dirt and new stone spread on and rolled in the same manner as a new construction.

(2) The surface is scarified before new stones are spread on.

The object of this is to enable the new stones to become more compacted with old material.

As to its advantage much difference of opinion exists. Some engineers maintain that it is not good to touch the compacted surface for the questionable advantage of securing better union of old stones with new. Others are of the opinion that the surface should be scarified, the stones sorted and cleaned, and relaid with the addition of new stones. In deciding which of these methods should be adopted it is necessary to consider all the circumstances. The thickness of existing surface and nature of roadbed must be considered. In the case of a thick surface, the surface should be scarified, but great care is necessary, as should surface be broken through to roadbed the foundation is liable to be injured.

With a thin surface and weak foundation scarifying should not be done as it is liable to make the road weaker than before. The author having had experience in both methods has had good results from each, though he is in favor of not disturbing the existing surface, which is the general principle carried out in Britain.

Maintenance of Macadam Roads.—The opinion that no road is a good one unless when once laid it will take care of itself is ridiculous; there is no such road. The

essential point in the preservation of a good surface is the vigilance on the part of road authorities. Should a depression appear in consequence of settlement, defective material, or other causes, it should be immediately eliminated. Best results are obtained and money is saved by immediate repairs on the road surface rather than leaving it until practically worn. Roads must be kept clean and, if possible, dustless.

When a road is finished and opened to traffic, it cannot be left to take care of itself; if so, it will soon deteriorate. The systems of maintenance in vogue are: (1) Contract; (2) personal supervision by rural population; (3) men employed by road authorities.

The author is in favor of the system of the work being done by men employed by the authorities, as in his opinion the men become familiar with the section under their supervision, and also seem to take an interest in the work, doing their very utmost to keep road clean and tidy. This is the system carried out in Scotland and other European countries, and it is to the thorough appreciation of this fact that the excellence of their roads is due.

The contract system is very unsatisfactory from the difficulty of getting a proper observance of the terms of the contract from contractor; this system has been tried in many places and has never given satisfaction.

The personal supervision by rural population or the statute labor system is not applicable to the upkeep of improved roads. It is unsound in principle, unjust in its operation, wasteful in its practice and entirely unsatisfactory in its results.

The rolling of a road in spring, after frost is out and before roadbed is dry, is one of the best means of keeping a macadam road in good condition. As before mentioned, great care must be exercised in watering and a road should not be watered unless it really needs it.

Macadamized Road with Tar Binder.—The tar binder has given good results, producing a road almost similar to an asphalt surface, almost noiseless, less wear and tear, less mud and dust than ordinary macadam.

Asphaltic oil has been used in many places as a binder for macadam roads and in very dry climates has given satisfactory results. The following method is employed: The existing surface of the road is covered with coarse sand of ½ in. thick. The oil heated to a temperature of 175° F. is then applied and is allowed to remain for 24 hours. This surface is then covered with ½ in. of sand, and oil again applied. This surface is immediately covered with sand sufficient to fill the liquid oil and remove stickiness. The surface is then rolled. Should surface lift under this treatment a little sand is applied again.

One of the first experiments tried by the author was treating of road surface with ordinary gas-works tar. This certainly kept down the dust and as a surface binder was fairly successful. But in hot weather it was continually running, and was more of a nuisance than otherwise.

Another method tried and highly successful as a dust preventative: calcium chloride was mixed in the proportion of 1 cwt. chloride to 100 gallons of water, and the mixture sprayed on to the road. This material served the purpose well, the absence of dust within a given period (almost three weeks) being the subject of favorable comment by residents. The cost worked out at 25 cents per mile for chemicals only.

A thin coat of tar of under-mentioned specification gives a fine surface in dry weather, but becomes dirty in wet weather under heavy traffic. During summer this method is very successful if used on streets under light traffic.

Specification: Specific Gravity—1.19 at 60° F.; Water—free; Fractionation—not more than 3% at 220° C., 15 to 20% at 300° C.; Free Carbon—15%; Viscosity—30 sec. at 70° F. The cost of this treatment was 5 cents per sq. yd. One gal. of tar covered 5 sq. yd. of surface.

A few years ago the author had a section of road treated with Tarvia "A," which was an exceptionally heavy tar. This road surface was in every way good, very regular in shape. The method was carried out in the following manner:

1st, Surface of road was thoroughly cleaned and swept free of dust; 2nd, the tar was heated and spread on road by means of sprinkling cans; 3rd, chippings of same quality of stone used on existing surface, which was very gritty, ½ in. to ¼ in. in size, free from dust, was spread on surface; 4th, the surface was then rolled with a 10-ton roller. The section treated was opened to traffic a few days after completion. The quantity of tar used was ¾ gal. to 1 sq. yd. of surface. The following year a similar treatment was applied, with the exception that the quantity of tar used was ¼ gal. to 1 sq. yd. of surface. This treatment gave excellent results, openings made in road a few months after second treatment showing that tar had really penetrated the surface to a depth of one inch, which greatly helped to bind the surface. It may be mentioned that this section did not get quite a fair trial as traffic conveyed upon it mud and dust from either end of the section, which caused a little more sweeping and watering than was necessary.

Before applying the tar the surface of road must be thoroughly cleaned, all dirt being removed so as to expose the stone surface. Should the surface not be cleaned in manner mentioned, or any cakes of dirt be allowed to remain, the tar will not penetrate into the macadam.

Surfacing with a substance called "Cormastik" is another method which has proved satisfactory. It is composed of ¼ in. to ⅜ in. granite chippings, sharp sand, powdered sicilian rock asphalt containing 10% of pure bitumen and Portland cement. The binder employed is Cuban natural asphalt refined and suitably fluxed. The existing surface of road having been thoroughly swept and cleaned and painted with the bituminous solution. The "Cormastik" is then spread in a heated state to a thickness of one inch, a wooden straight edge being used for levelling, and finally rolled to a smooth surface by a 3-ton tandem roller.

This surfacing is also made up in brick form 9 x 4½ x 2 in. thick laid on a concrete foundation and suitable for heavy traffic.

Pitch Grouted Macadam.—The size of stones used was 2½ to 1¼ in. with chippings from ¾ to ⅜ in., the finished thickness being 3 in. The stone, spread and levelled, is rolled dry until proper surface has been formed. The pitch, after being melted, is heated to a temperature of 300° F. Clean, sharp sand is added to this, mixed thoroughly in mixing vessels and transferred from these into cans, from which it is poured upon the road. On this surface a thin layer of chippings is applied. The quantity of pitch used was 2 gal. to a sq. yd. of surface. This method is fairly satisfactory in some districts. In the author's experience the pitch boiled out in hot weather leaving the road in dirty condition. The crown of the road became bare of pitch, the sides getting

the surplus. The stones were never thoroughly coated, thus allowing water to get into the crust.

The method employed in one instance was a double layer. The size of stones used for the lower layer was 3 to 2 in. and for top layer 1½ in. with ½ in. chippings. The lower layer of stone is spread and levelled and is rolled dry. The pitch and sand mixture (as above described) is poured on, but not brought to surface. The pitch lying ½ in. or so below surface of the lower layer to form a key for top layer.

When the top layer has been laid, the pitch mixture is poured on surface, which is rolled and consolidated to proper shape. During rolling chippings are applied to form finished surface.

The quantity of pitch mixture used was 3½ gal. per sq. yd. for the two layers. The finished surface in this case was 4½ in. thick. This method was very satisfactory during the year, almost dustless, and not slippery during frost.

(To be concluded next week.)

ELECTRICAL DRIVING OF WINDING ENGINES AND ROLLING MILLS.

In a very complete and well-illustrated paper, delivered last month to The Canadian Society of Civil Engineers and to the Canadian Mining Institute, C. Antony Ablett, A.M.Inst.C.E., and H. M. Lyons, A.M.I.E.E., described the use of electrical machinery for driving hoisting engines in mines and reversing mill plants in steel works.

The first winders of importance were introduced in 1902, and the first electrically driven reversing rolling mill was installed in 1906, though non-reversing rolling mills were driven electrically some eight or ten years earlier.

The developments along these lines have been extremely rapid, as is shown by the fact that at the present time about one thousand large winding engines and nearly sixty reversing rolling mills are being driven electrically. The earlier winding engines were extravagant in power and had the disadvantage of drawing very heavily upon the source of electrical supply at the moment of starting. It was, therefore, impossible to use them on systems where the supply of current was limited, and even on comparatively large plants their use resulted in serious interference with other machinery. These disadvantages were, however, practically done away with when the Ward Leonard system and Ilgner's adoption of the flywheel to this system were introduced, but the last few years have seen greater improvements in the Ward Leonard and the Ilgner system.

The paper delivered by Messrs. Ablett and Lyons dealt chiefly with the developments of these systems by the various Siemens companies, who have installed about half the total plants in existence, and with whom the authors are associated, as general manager and assistant manager, respectively, of Siemens Company of Canada, Montreal. Following is a very brief abstract of the paper:—

In the Ward-Leonard system a direct current motor is used to drive the winding engine or rolling mill, the motor being supplied with power from a direct current dynamo, and the essential feature of this system is that the voltage supplied to the motor, and consequently the speed of the motor, is controlled by controlling the field current of the generator, instead of by varying the resistance in the armature circuit of the motor.

Thus, as the field current of the generator is increased from nothing to a maximum, the motor speeds up from standstill to full speed, and if the field current of the generator is reversed, the motor reverses its direction of rotation.

This system enables a very exact control of the speed to be obtained, because the speed of the motor is practically proportional to the strength of the generator field, whatever the load on the motor may be, while with any control system where resistances are inserted into the armature circuit of the motor, the speed would vary within very wide limits with a change of load, rendering the exact speed control quite impossible.

The control of the dynamo field involves scarcely any waste of electrical power, but where resistances are inserted into the armature circuit the loss of power may be, and usually is, very great. The field currents of the generator are small, so that the control mechanism is small, compact and very easy to handle, the armature currents are perhaps fifty times as great, so that any control mechanism which varies the resistance of the armature circuits is large, clumsy and difficult to handle, in fact a complicated relay system is often necessary to enable it to be handled at all.

The dynamo used to supply the motor in the Ward-Leonard system is usually driven by a motor supplied from the available power circuit, forming a motor generator set, and this motor may be either direct current or three-phase, according to the power available. The dynamo may be, and sometimes is, driven by an engine, water turbine, or other prime mover, if this happens to be more convenient.

The paper gives a full description of the application of the Ward-Leonard system to winding engines and hoists under the titles of Speed Control, Use of Flywheel, Details of Ilgner System, Brake Gear and Safety Devices.

It also describes the application of this system to reversing and three-high rolling mills, discussing power diagram for reversing blooming mill, action of flywheel, safety devices, etc.

A three-phase motor cannot be built for a very low speed without its power factor being bad, which tends to upset the regulation of the supply system, and for this reason where three-phase motors are driving winding engines they nearly always run at higher speeds than the drums, and are geared to them. In the Ward-Leonard or Ilgner system, however, where a direct current motor is used, this is almost invariably direct coupled to the drum. The three-phase system was described under the following headings: Control, Power Diagram of Three-Phase Winder, Comparison of Three-Phase Winder with Ward-Leonard and Ilgner Winders, Lowering Load, Starter and Controlling Resistances, Emergency Gear, Winding Men and Shaft and Rope Inspection.

As a number of winding engines have been equipped with three-phase commutator motors, an account of that system is also given.

The conditions governing the selection of the type of drum differ very considerably, according to whether the winder is to be driven electrically or by a steam engine. It is characteristic of the steam engine that its overload capacity is not very great and that the turning moment varies according to the position of the cranks. For a two-cylinder engine with cranks at right angles, such as is usually used for a steam winder, the minimum turning moment is .785 of the mean turning moment, and

the maximum turning moment is 1.112. The engine naturally must be able to start the hoist with the cranks in any position, so that the minimum turning moment must be at least sufficient to overcome the static load and friction. An electric motor, on the contrary, has a very large overload capacity in proportion to the mean power which it will give, and, consequently, the motor for winding engines is usually selected with reference to the equivalent continuous load, and it is very rarely indeed that the starting moment or acceleration peak needs to be considered.

The first type of drum to be employed for winding engines was the cylindrical drum, but later the conical drum was introduced. In some cases the latter gives easier starting conditions and is beneficial to the steam engine, because the rope supporting the cage at the bank top is wound off the greatest diameter, while the rope attached to the loaded cage at the pit bottom is wound on to the least diameter, so that the empty cage partially balances the rope and the loaded cage at the start of the wind.

The Koepe pulley winder is used to a considerable extent in Europe, particularly in Germany. It differs from any other type, as the rope is not wound on to and off drums but is carried over the pulley and makes contact with it for less than a single turn. Thus the rope from the ascending cage comes up the shaft over the driving pulley by the winder, and then down to the descending cage, being suitably guided by head sheaves.

It will thus be seen that the winding rope is driven by friction alone, and, consequently, there must be a very definite limit between the pull in the ascending rope and the pull of the descending rope, otherwise the rope will slip on the pulley, and, to keep the difference in pull of the two sides of the rope as small as possible, a balance rope is always necessary.

It should be noted that such a winder cannot work with a very high acceleration, otherwise slipping of the rope will take place. As the rope is bound to creep on the pulley to a certain extent, the depth indicator must frequently be reset to ensure its accuracy.

As with a Koepe pulley winder the axial length of the pulley is very short indeed compared with that of a drum on which the rope has to be wound, and as the weight of the winding drum is not increased by the rope which it is carrying, the moment of inertia of the revolving parts of a Koepe pulley winder is small, and this, together with the use of the balance rope, keeps the maximum acceleration peak comparatively small compared with that of other types of winder.

Generally speaking, the Koepe pulley winder shows to the greatest advantage with deep shafts as it avoids the use of excessively long drums, and, from the electrical point of view, where the winding speed is not very high and where the acceleration period is short compared with the total time of winding. It has the disadvantage that if the rope breaks, both cages are detached from the winder.

Table Showing the Influence of the Different Types of Drums on the Electrically Driven Winding Engine.

Depth 1,600 feet. Output 270 tons per hour.

	Cylindrical Drum	Conical Drum	Scroll Drum	Koepe Pulley
Power of motor	1,090	965	780	935
Speed of motor	84	66	62.7	97
H.P. per revolution ..	12	14.6	12.4	9.6
Maximum peak with Ward Leonard system	1,86[illegible]	1,600	1,300	1,276
Average loss of power with three-phase system	225 H.P.	260 H.P.	170 H.P.	241 H.P.

Generally speaking, the authors are of opinion that the Ward-Leonard or Ilgner system of electric winding is the most suitable for vertical shafts, and for all cases where large outputs are required and short and frequent winds are made. The three-phase winder always has the disadvantage that it cannot be so completely protected against careless handling as either the Ward-Leonard or the Ilgner, but it may prove more economical for long slopes where the full speed run is a long one and the periods of acceleration are comparatively infrequent.

Regarding the choice of drums for the winding engine, the authors are of opinion that in many cases where electrical drive is adopted, the cylindrical drum winder will prove the most suitable, but that in cases of deep shafts where the winding speed is high the scroll drum winder may prove better than the cylindrical drum winder, but that the field of application of the conical drum winder to electric winding is very small.

The authors have purposely avoided any comparison between the running costs of a steam and an electrically driven hoist or rolling mill, because each case should be considered on its own merits and comparisons made for one case will not be valid for another where conditions are different. No general comparison has any practical value, sometimes the steam engine is the more economical, and sometimes the electrical plant, according to conditions, and in deciding which is the more advantageous there are other factors besides running costs to be considered.

The authors are of opinion that direct current is much better adapted for driving mills and machinery in a steel works than three-phase current. Where large reversing rolling mills are driven electrically, and the motor driving the motor generator set is supplied from a direct current system, it is found that the power supplied to the rolling mill plant can be maintained at a much steadier value than if it is supplied from a three-phase system, and with the direct current motor about a ten per cent. saving in power can be effected, as there is no loss of power in slip resistances.

With a direct current system the flywheel of the motor generator set can be utilized to a great extent for neutralizing sudden peaks of short duration in the power demand on other parts of the system, for, during such a peak, the motor generator set would not only cease to take power from the supply, but the motor can be actually reversed, and give its full output as a generator returning the energy of the flywheel as electrical energy to the supply system.

With a three-phase system, peaks in other parts of the system cannot be neutralized to anything like the same extent, for the motor can only be made to cease to take power from the supply system and cannot act as a generator returning power to the supply system.

The direct current compound wound motor is very well adapted to fulfil the conditions for driving three-high merchant and bar mills and that considerable complication and difficulties are involved in adapting the three-phase motor for this purpose.

Direct current motors are also particularly well adapted for driving slow speed sheet and tinplate mills, and it is very easy to provide a slow speed direct coupled motor and gain the advantage and economy of this drive, and, as there is no loss of power in slip resistances, the direct current motor will prove from twelve to fifteen per cent. more economical than the three-phase motor on this current alone.

The advantages of direct current table and live roll motors are fully recognized, but it is interesting to note that in perhaps the largest steel works on the American Continent, where the main power supply is three-phase, all the table motors are direct current and a large and costly installation of converting machinery has been provided to convert the three-phase current to direct current to supply these table motors.

It may be argued that the cost of cables with a 500-volt direct current system is much higher than for a high voltage three-phase system, but it must be remembered that a well laid out steel works is comparatively compact and the distances are relatively short, so that the cost of cables is not a very serious item, and that the additional capital cost of three-phase generating plant to produce power, which is wasted in the slip resistance, etc., will pay for a good deal of extra cable.

In steel works where there are blast furnaces and coke ovens, the modern tendency is to install large gas engines using blast furnace or coke oven gas, both for driving the blast furnace blowers and for generating electrical power, and experience shows that a direct current gas engine power house is cheaper in capital cost and easier to operate than a three-phase power house.

Gas engine driven three-phase alternators present the most difficult problem in parallel running, and while sufficient experience has been gained in the past ten years to enable these difficulties to be overcome by proper design, the provision of very heavy flywheels is always necessary, and these largely increase the capital cost of the three-phase generators, which are intrinsically more expensive than direct current generators. The higher the periodicity the heavier the flywheels for the three-phase generators become. The 500-volt direct current system has found very wide application in the steel works on the Continent of Europe.

DIESEL ENGINE EXHIBIT AT THE PANAMA-PACIFIC EXPOSITION.

It is announced by the Department of Machinery of the Panama Pacific International Exposition that more than a dozen large firms have contracted for space in which to install engines built on the Diesel principle. These exhibits will occupy a central space in the great Palace of Machinery, and will be under operation through connection with electric generators or other machinery for the purpose of showing the efficiency and economy of working.

It will be recalled that the tragic death of Dr. Rudolph, inventor of the motor, by drowning in the English Channel, which occurred in September, 1913, was almost simultaneous with the final triumph of his ingenious motor by its adaptation to railway traction on a large scale.

NATIONAL IRRIGATION CONVENTION.

Arrangements are being made for a National Irrigation Convention to be held in Calgary next September. A fund of $20,000 is practically assured for it. The convention will bring a large delegation of irrigationists from Oregon, Washington, Montana, Idaho, Utah, Texas, California and other States. Irrigation work in Canada has created a good deal of interest in the country to the South, and the gigantic project of the Canadian Pacific Railway, as outlined in *The Canadian Engineer* for January 1st, 1914, will receive a thorough inspecting by many irrigationists who are extremely interested in the enterprise.

A detailed programme of the convention will be announced at an early date.

THE ZOELLY STEAM TURBINE.

In 1898, Mr. Zoelly designed a new type of steam turbine which resembled in many respects a water turbine of the impulse type. This machine was designed on the radial flow principle. The blades were not curved. A second machine with curved blades gave better results, however, the steam in this case striking against the rotor blades in radial direction. The principle of the impulse type has been adopted from the commencement as being the best, and the only alterations that took place were in the manner of guiding the steam onto the wheels. The turbine has gone through many stages of improvement which, however, have been solely of a constructional character. No departures from the adopted principle have taken place. On the original type the governing is effected simply by throttling the live steam and not by varying the number of channels through which the steam is admitted.

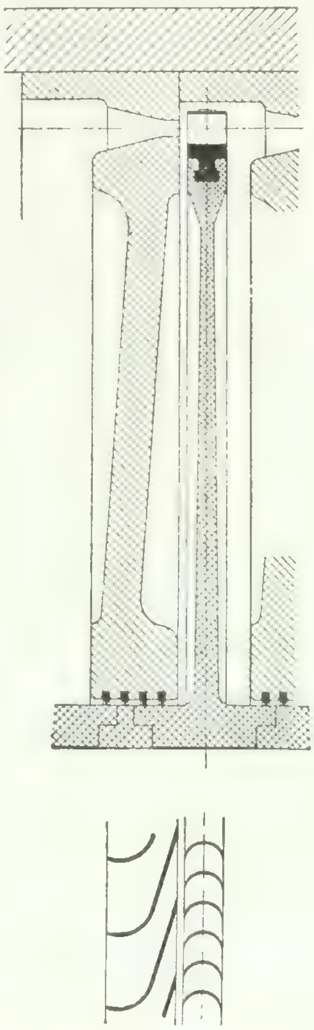

Fig. 1.—Runner and Guide Wheel of Zoelly Turbine.

This turbine has, in the past, been subjected to a good deal of criticism respecting the steam pressure and temperature in the first stage which were considered to be excessively high and which were supposed to have a deleterious effect upon the stuffing boxes. In the case of the present Zoelly turbines these criticisms are without foundation as in the first stage a greater pressure drop and likewise a correspondingly higher steam velocity is made use of than previously. This velocity equals or even surpasses that of sound corresponding to the steam conditions of this particular stage.

In order to be able to construct large units without having to employ too large blades in the last two stages, these stages are provided with a greater drop of pressure so that they also work with steam velocities which may be five and even more per cent. higher than the velocity of sound. The intermediate pressure stages work with steam velocities which do not, or only in a very slight degree, exceed the velocity of sound belonging to the conditions of these stages. At any rate, the excess of velocity over that of sound is in the intermediate stages never so great as in the first and last stages.

The total drop of pressure available has been divided up in such manner that it has been impossible to reduce the number of stages and thereby shorten the turbine by an appreciable amount. If necessary, these stages are constructed with expanded guide channels or nozzles. This expansion is not, however, designed for full load

but only for about half or a quarter of full load, in order to ensure a good efficiency even at part load. Such types of Zoelly turbines have been built since 1908.

The characteristic feature of the Zoelly turbine has always been the design of the runner wheels and guide channels in the diaphragm, the former of which, in spite of the high factor of safety required, are enabled to give a relatively high circumferential velocity. Consequently greater latitude is permissible in regard to the number of stages and speed of the steam in each case.

Construction.—From the commencement the Zoelly turbine has always been constructed with a horizontal shaft; experience with water turbines has shown that by this method the simplest form of bearing can be used, permitting an easy inspection at all times. In the case of turbines running at 3,600 r.p.m. a flexible shaft is used, so that the critical speed is sufficiently below the working speed; but in the case of turbines running at 1,800 r.p.m. and under, the contrary is the case, the shaft is rigid and the critical speed is above the working speed. The shaft is supported by two bearings which are lubricated by oil under pressure, and is connected by means of a rigid or flexible coupling (usually rigid) to the generator or machine to be driven. The casing is built up in two halves, the joint being horizontal, so that the rotor can easily be inspected without dismantling the bearings. An idea of the accessibility of all the important parts can be gained from the illustrations shown.

To keep the velocity of the steam low, which is possible in the simple velocity wheel, the wear in the blades, specially when working with saturated steam, is reduced to a minimum.

The impulse type allows large clearances in radial and axial direction. The axial clearances of the runner blades as well as the radial clearances are about 0.2 in. Nevertheless, the steam consumptions obtained with the Zoelly steam turbine are extremely low, particularly for the large size high-speed units.

The turbine is what can best be called a commercial machine, i.e., a machine giving with the greatest reliability best economy and least wear, with a minimum of attendance required.

The total thermodynamical efficiency obtained has been as high as 74%.

Since this turbine came on the market 11 years ago, it has done excellent work. Twenty firms are at present licensees of the Escher Wyss Company, of Zurich, who built the first machines and who have since supplied the bulk of the machines put on the market.

Up to 1913, Zoelly turbines of 3,350,000 h.p. have been supplied, of which those built by Escher Wyss and Company had a capacity of over 800,000 h.p. The largest size machine was 15,000 kw., equal to 28,000 h.p., of which two units were supplied to the Rheinisch-Westfaelisches Elektrizitaetswerk (Germany) — one in 1911 and the second as a repeat order in 1913.

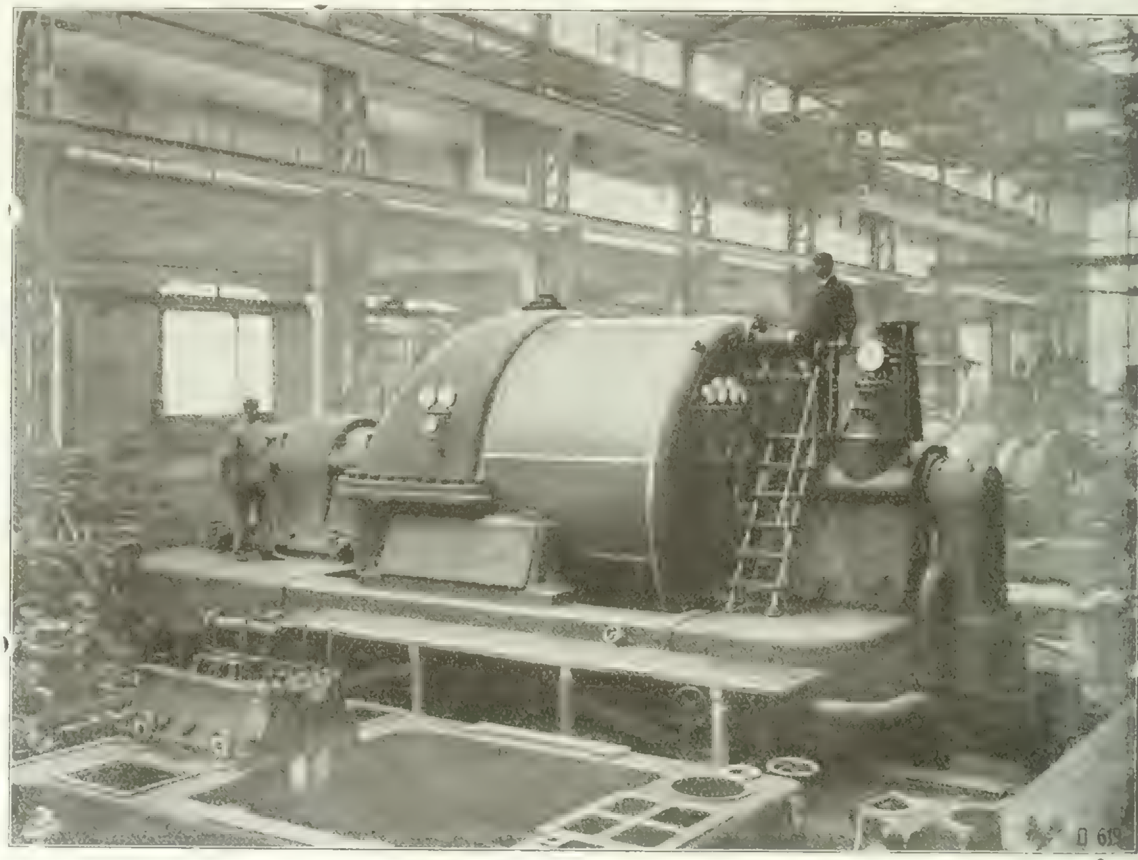

Fig. 2.—15000-kw. Escher Wyss-Zoelly Steam Turbine.

A number of machines of similar size have been built for other concerns; such as, a plant of four 10,000 kw. units for the Chile Exploration Company, of New York.

The *Engineering Record* describes the recent feat accomplished in subway tunnelling in New York city thus:—"For the first time in the history of subaqueous subway construction in New York city, a radical departure from the usual methods of building the tubes in place by compressed air tunnelling methods has been made. An 8,000-ton section of four-track steel lining, 220 feet long, 26 feet wide and 24 feet deep, which had been assembled and riveted on shore, was floated out into the Harlem River and sunk into position through 60 feet of water. The enormous mass was at all times under perfect control, was handled without any surges, plunges or violent or dangerous movements, and the structure was placed in position far below the surface without the use of guides or complicated apparatus. Work was carried out strictly in accordance with a detailed schedule of time and operation, which made ample provision for all the difficult conditions under which the work was executed."

Coast to Coast

Guelph, Ont.—The bridge leading from Riverside Park to Wellington Place and to the Guelph Country Club has been formally opened.

Victoria, B.C.—The civic board of works of Victoria has prepared estimates for 1914 calling for a requirement of $1,041,136.40, a considerable increase over the outlay in 1913 of $969,427.70.

Brantford, Ont.—By an overwhelming majority Brantford [illegible] ford Street Railway and Grand Valley Railway from Brantford to Galt for the sum of $253,000.

Vancouver, B.C.—With an expenditure of between $15,000 and $20,000, the C., M. and St. P. Railway Company has purchased its right-of-way at Sumas preparatory to linking up its line with the B.C. Electric railway, over which rails it will enter Vancouver until its own line is finished.

Toronto, Ont.—It is reported that the first of this month is to make the commencement of operations upon the harbor development scheme in Toronto. The great undertaking will be started at Ashbridge's Bay to the east of the mouth of the Don, where three piledrivers [illegible] to be supplemented by other drivers.

Hamilton, Ont.—At a recent meeting of the Hamilton Works Committee it was announced that the estimate of the Hydro Department for street lighting has been amended, the new figure being $88,125, whereas the original estimate was $64,200. It was explained that 25½ miles of streets had been added to the original estimate, and that some of these had to be lighted on both sides.

Vancouver, B.C.—Estimates recently furnished for 1914 on the partnership main between Point Grey and Vancouver, totalled $294,740, as compared with $213,394 last year. The principal increase is for submerged main maintenance. Under this head last year less than $1,000 was spent, but this year the replacing of the main on account of the government dredging is estimated to cost $100,000.

Ottawa, Ont.—On March 20, supplementary estimates, amounting to $3,257,036 for the fiscal year just ending, were tabled in the Commons by the Minister of Finance. This brings the grand total of the estimates voted for the year to almost $206,000,000. Of the supplementary estimates, the additional amount required towards the completion of public works was $264,204.

Ottawa, Ont.—The annual report of the Ottawa electric department has been recently submitted to the city council. The revenue for the year amounted to $191,648.64, as follows: domestic lighting, $68,032.27; commercial, $53,438.04; power, $26,978.76; street lighting, $32,637.73; ornamental lighting, $10,561.84. The expenditures totalled $142,283.54; leaving a gross surplus of $49,365.10, of which $24,000 was written off for depreciation, admitting a net surplus of $25,365.10.

Edmonton, Alta.—The extension of the P.G.E. railway into the Peace River district of Alberta, a line which, it is stated, will be a subsidiary road of the G.T.P. system, will start from the confluence of the Fraser and Salmon Rivers, following the latter to Summit Lake, thence along the Crooked River to Fort McLeod and McLeod Lake, thence along the Missinchinka River, through Pine Pass and along the Pine River to Hudson's Hope, following the peace River to the Alberta boundary, connecting with the McArthur railway.

St. John, N.B.—A conference was held recently at St John between the city commissioners and the members of the board of trade with reference to the Valley Railway extension and bridges. The outcome was the general endorsation of a suggestion that the road be allowed to end at the point it has reached,—e.g., Gagetown—unless it can be finished to St. John, as originally planned. The board of trade will, however, continue to deal with the matter and will probably send a delegation to Ottawa to urge further federal aid for the bridges which would have to be constructed on the extension to St. John as originally planned

Vancouver, B.C.—Mr. J. W. Stewart, president of the P.G.E. railway, has announced that employment will be given to 12,000 men this year on construction work. Three important contracts have been let covering the proposed Kelly Lake-Fort George line, which is some 280 miles in extent. Only 100 miles, however, are included in the contracts issued. As the contractors have just finished work on the G.T.P. railway at Fort George, the new work will begin at once, and it is expected that this entire section will be completed next year. The contract for the first 100 miles of the extension north of Fort George into the Peace River country will be let by the end of next month.

Toronto, Ont.—The following is part of a resolution which was carried unanimously on March 25th in the Ontario legislature: "In the opinion of this House, cheap and convenient electric railway transportation facilities is one of the most urgent needs in many rural sections and towns of the province, and this House would respectfully urge upon the Dominion government the importance of the question and the wisdom of encouraging the construction of municipal Hydro-Electric radial railways, and that this House further respectfully urge upon the Dominion government the great importance of co-operating with the province in the development of the water powers created by existing and projected canals now under construction and capable of development by the utilization of the waters necessarily supplied thereto and not required for navigation purposes."

Quebec, Que.—The Dorchester Electric Company, of Quebec, which has been in operation only about fourteen months, has completed its first year with a satisfactory surplus of $4,000; and the earnings for the first months of 1914 showed a rate much in advance of this, a surplus of $1,379 remaining after interest and other fixed charges were met. The company is extending its business substantially and is gradually cutting down operating expenses. The company's largest contracts are the lighting of the streets and municipal buildings of Quebec for a period of 10 years, a contract with the town of Montcalm for the same period, and a similar contract for Charlesbourg for the same period. The peak load which the company can carry is 1,640 h.p. At present customers are taking about 1,500 h.p. for lighting purposes; and the motor load is only 827 h.p.

Taghum, B.C.—The contractors for the Taghum bridge, Hodgson, King and McPhalen Bros., of Vancouver, are confident that the structure will be ready for traffic by May 1st. Work on the three main spans is being rushed to completion; and in addition to these, which are of truss design, there are two short spans to be placed in connection with the approach to the bridge from the south side. These, however, can be placed, no matter what the condition of the water may be. At present the contractors are exerting all their energies on the three main spans, so that these may be completed before any material rise in the water takes place. Costing in the neighborhood of $100,000, the bridge, which will be finished well within contract time, is almost entirely a product of British Columbia. Cement manufactured at Princeton, steel fabricated at Vancouver, and lumber grown in this province, are the materials which have been used.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page [illegible] a directory of such societies and their chief officials.

CANADIAN SOCIETY OF CIVIL ENGINEERS, OTTAWA BRANCH.

The last evening meeting for the season of the Ottawa Society of Civil Engineers was held on April 2nd, when Walter J. Francis, C.E., Consulting Engineer, of Montreal, delivered an address, entitled "The Engineer and the Public." The meeting was held in the Board Room of the Commission of Conservation, and was attended by 75 members. Mr. Francis advanced many arguments in favor of a united effort on the part of engineers to elevate the profession, claiming the best ways for accomplishing it to be a better education of the young man entering it, the maintenance of a proper standard of dignity, and perfection in the work of the engineer, and co-operation with fellow-engineers.

The address was followed by an excellent discussion, Messrs. R. F. Uniacke, C.E., C. R. Coutlee, C.E., Noulan Cauchon and others taking part. Mr. Geo. A. Mountain was chairman.

NOVA SCOTIA MINING SOCIETY.

The annual meeting of the Nova Scotia Mining Society will be held in Sydney, N.S. on April 14th and 15th. Indications are that it will be the most successful gathering in the history of the society. Addresses and technical papers have been prepared which will be read by a representative list of men in mining in the Maritime Provinces, and the programme gives evidence of a comprehensive review of the entire mining industry as applied to Eastern Canada. The principle topics under discussion will be electricity in mining and coal. The following is a list of some of the speakers together with the subjects which they will present:—

"Distillation of coal"—F. E. Lucas.

"Fletcher's unfinished work"—W. N. McDonald.

"Longwall machine mining"—J. F. K. Brown.

"Longwall development at Jubilee Colliery, Sydney Mines"—Robert Robinson.

"Electric motors for various services in the mining industry"—C. H. Wright, Halifax.

"Cinematographics and science"—Alexander Theuerkauf.

"A mining engineer of the fifteenth century. De Re Metallica Georgius Agricola, 1545"—F. W. Gray.

"Mine fatalities"—Robert Drumond, Stellarton.

"Use of typographical survey maps in mining"—R. Boyd.

"Shipping piers"—D. H. McDougall.

"Methods of mining two coal seams lying near together"—W. Herd.

"Coal as seen under a microscope"—A. J. Tonge.

It is expected that R. W. Brock, Deputy Minister of Mines, Ottawa, will be present and will deliver an address.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.

The 7th annual assembly of the Royal Architectural Institute of Canada will be held at Quebec, Que., on September 21st and 22nd, 1914. A very interesting programme is being prepared, which will include matters of interest to every Architect in the Dominion. The programme will be sent early in August to all the members of the R.A.I.C., and will contain all the particulars. The committee of arrangements of the Assembly is composed as follows: J. H. G. Russell, Jos. P. Ouellet, René P. LeMay, Albert R. Décary, and Alcide Chaussé, Hon. Secretary.

DINNER TO DEAN GALBRAITH.

The graduates of the Faculty of Applied Science and Engineering, University of Toronto, who are resident in Ottawa, held a dinner on March 28th, in honor of Dr. John Galbraith, Dean of that Faculty. The banquet, held at the Chateau Laurier, was attended by over 80 graduates. The function was most successful and great credit is due to the organizers. It is the first dinner of this kind that the graduates in engineering of the University of Toronto, who live in Ottawa, have held.

Prominent among the representatives from other centres were Major C. H. Mitchell, Consulting Engineer, Toronto, and a member of the Board of Governors of the University of Toronto; Professors C. H. C. Wright and T. R. Loudon, representing the Faculty of Applied Science and Engineering; Mr. J. L. Morris, Civil Engineer and Surveyor Pembroke, the earliest graduate of the institution; J. M. R. Fairburn, Assistant Chief Engineer of the Canadian Pacific Railway, Montreal; Walter J. Francis, Consulting Engineer, Montreal; G. H. Duggan, Vice-President of the Dominion Bridge Company, and others.

An important outcome of the gathering was the appointment of a local committee, consisting of Messrs. T. Shanks, J. B. Challies, R. S. Smart, F. D. Henderson, F. D. Withrow, P. F. Morley, G. H. Ferguson, J. L. Stacey and W. F. M. Bryce, to arrange for a permanent organization to take the form of Ottawa branch of the Engineering Alumni Association of the University of Toronto, and to be similar to the branches existing in various parts of Canada and the United States.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Diven, 47 State Street, Troy, N.Y.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9-13, 1914. J. E. Pennybacker, Secretary, Colorado Building, Washington, D.C.

AMERICAN PEAT SOCIETY.—Eighth Annual Meeting will be held in Duluth, Minn., on August 20, 21 and 22, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

AMERICAN SOCIETY FOR TESTING MATERIALS—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal.

MANITOBA ENGINEERING SOCIETY.

The Engineering Society of the University of Manitoba has recently issued the 1914 number of its official publication, "The Manitoba Engineer."

ARCHITECTURAL CLUB, UNIVERSITY OF TORONTO.

Plans for a power-house contemplated by the Water Power Branch, Department of the Interior, for the generation of electrical energy at Cascade River, near Banff, Alta., were drawn in competition in the Department of Architecture, University of Toronto. Of the resulting designs Mr. A. C. Wilson, a 4th year student, submitted the first prize winner. Mr. Merrill Denison of the 3rd year and Mr. Lester Husband of the 2nd year received the 2nd and 3rd prizes, respectively.

PERSONALS.

J. W. BATTERSHILL, at present in the City Engineer's office, Winnipeg, has just been appointed Engineer to the Municipality of East Kildonan.

R. A. BARRETT, Superintendent of the Toronto, Hamilton and Buffalo Railway, has just resigned owing to ill-health and has been succeeded by H. T. Malcolmson.

WALTER J. FRANCIS, C.E., consulting engineer, of Montreal, is at present on a trip to investigate sewerage and water supply problems in several cities of Western Canada.

H. T. ROUTLY, B.A.Sc., of Routly and Summers, left last week for Huntingdon, P.Q., to get his road machinery and equipment into shape for several large contracts which he has in hand there for this season.

WALLACE BROAD recently addressed the Engineering Society of the University of New Brunswick on "Engineering in China." Mr. Broad, an old graduate of that university, has spent considerable time in the Orient, and was for a lengthy period mining adviser to the Chinese Government.

ARTHUR L. MUDGE AND A. LEO MIEVILLE have become associated with Kerry and Chace, Limited, consulting engineers, Toronto, as managers of the electrical and mechanical branches, respectively. Mr. Mudge for over four years was chief electrical engineer for the Toronto office of Smith, Kerry and Chace, during which period they had charge of the design and construction of a large number of hydro-electric plants and long distance transmissions. For the past year Mr. Mudge has been chief engineer of the Midland Construction Company, which carried out most of the construction work for the Electric Power Company. He is first Vice-President of the Canadian Electrical Association and is on the library committee of the Toronto branch of the Canadian Society of Civil Engineers.

Mr. Miéville was at one time designer of high-speed machinery for W. H. Allenson and Company, Bedford, England, a firm for whom he acted until recently as engineer in Canada. Previous to this, Mr. Miéville had been assistant engineer upon the construction of the Winnipeg hydro-electric development, and turbine designer with the I. P. Morris Company, Philadelphia. Before leaving England, Mr. Miéville was for several years engaged upon paper mill engineering, and latterly in marine work, designing engines, turbines and general machinery for British and foreign admiralties.

OBITUARY.

CHARLES L. SMITH, General Manager of the Oregon Short Line Railroad, died last week at St. Catharines, Ont.

IRON AND STEEL OUTLOOK IN THE UNITED STATES.

The outlook for the iron and steel business in the United States is somewhat mixed. Orders on the books of the various mills at the beginning of April show a falling off as compared with the beginning of March, and a slowing down of operations is observed. This is more especially the case among the smaller than the larger producers. For prompt delivery, prices of the heavier lines, such as shapes, plates and bars, for second quarter contracts, are quoted at $1.25 Pittsburg, as against $1.20 for the first quarter, the efforts on the part of the mills to advance the price of the former $1 over the latter having failed. However, there has been a little more activity in the Eastern States for iron. No. 2 Birmingham iron has gone off 25 cents a ton, wire rods 50 cents and steel bars $1, as compared with the prices a week ago. On the other hand, a report comes from Pittsburg that the prices of billets and steel bars have been advanced $1 a ton to $22 and $23, respectively, at the mill, sales at these prices having taken place. In the East the market for finished steel is practically at a standstill, while a marked slowing up is observed in the Western markets for sheet and cast-iron pipe. While prices are keeping up well, the spring demand for wire products is expected to be below normal.

HOOK FOR MEASURING TAPES.

This hook, when attached to the first end of a steel measuring tape enables one person to take long as well as short measurements readily, while ordinarily two people are required; one at each end of the tape. It is a new article just put out by the Lufkin Rule Co. of Canada, Limited. It is a substantial, nickel plated hook with serrated face, and is designed so that it can be instantly attached to the first end of ¼ in. or ⅜ in. wide steel tapes. The hook grips the end of the article to be measured, and is so constructed that when attached to the first end of any regular tape measuring from the end of the ring, the zero point falls exactly at the inside of the hook so that measurements obtained are accurate. The hook can be as readily detached from as attached to tapes, in no way interfering with the use of the tape in the regular manner.

Vitrified Clays, Limited, announce the removal of their Calgary offices from the P. Burns Building to 236 Laugheed Building.

The offices of the Toronto Harbor Commission have been moved from the Bell Telephone Building to a more spacious location in the Otis-Fensom Building, 50 Bay Street, Toronto.

The city of Vancouver laid the following lengths in miles of pavements during 1913, according to the recent report of Mr. F. L. Fellowes, Supervising City Engineer:—Asphaltic concrete, 1.161; bitulithic, .248; granitoid, .179; brick block, .124; concrete, .026; wood block, .462; total, 2.200 miles.

The record of the Department of Labor for February shows that there was a pronounced decrease in the number of days lost through strikes and lockouts, as compared with the previous month, although the number was somewhat larger than for the corresponding month of last year. The decrease was largely due to a settlement of a strike of shoe machine workers in Quebec, about 3,000 employees returning to work on February 14. There were altogether seven disputes in existence in Canada during February, as against five in January and nine in February of last year. About 23 firms and 4,400 employees were involved in these disputes. Approximately 66,[illegible] working days were lost [illegible] th 117,450 during January, and 42,880 during February of last year. Three disputes commenced during February, none of which were serious from the standpoint of numbers affected. They were all, moreover, of short duration. The dispute of coal miners on Vancouver Island and garment workers at Montreal remained unsettled at the end of February.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21534—March 24—Amending Order No. [illegible], dated December [illegible], by striking out words and figures, "Between Southeast Quarter of Sec. 9, and Northeast Quarter of Sec. 16," in description of crossing No. 8 in operative part of Order, and substituting therefor words and figures, "Between the S.E. ¼ of Sec. 16 and the N.E. ¼ of Sec. 9."

21535—March 24—Authorizing C.P.R. to connect with its main line, Lake Superior Div., Cartier Subdivision, the spur of Mond Nickel Co., Limited, at mileage 103.25 of main line, in Lot 8, Con. 5, Tp. Dowling, Dist. Sudbury, Ontario.

21536—March 24—Authorizing G.T.R. to operate trains across fifty-seven (57) bridges.

21537—March 23—Authorizing G.T.R. to construct two (2) bridges—namely, No. 29, mileage 83.50 19th Dist., over Grand River, nearest station, Paris; and No. 21, mileage 76.02, 19th Dist., over Brantford and Tilsonburg tracks, nearest station, Brantford. all in Province of Ontario.

21538—March 24—Authorizing G.T.R. to construct bridge No. 257, at mileage 25.25, 13th Dist., in town of Milton, Ont.

21539—March 23—Authorizing G.T.R. to construct five (5) bridges, on its 12th District, Province of Ontario.

21540—March 23—Authorizing G.T.R. to construct siding into premises of Pelleyrino Del Sole, on Lot 105, parish of St. Bruno, Co. Chambly, Que.

21541—March 25—Suspending, tariffs and supplements applicable to international traffic, filed by G.T.R., M.C.R.R., Wabash, R.R., C.P.R. and P.M.R.R., pending hearing, to be fixed by Board, at which said Cos., will be required to justify said removal of Essex Terminal Ry. from joint tariffs, at present in effect.

21542—March 4—Authorizing Cedars Rapids Mfg. and Power Co., of Montreal, to take additional width of 25 ft. for its right of way for its transmission line, making in all a width of 125 ft. across certain lots known as Lots 262, 266, 267, 268 and 269, parish of St. Ignace du Coteau du Lac, property of Idala Charlebois; and Lot 183, parish of St. Polycarpe, Co. Soulanges, property of Charles Houle.

21543—March 19—Authorizing G.T.R. to expropriate lands between Yonge and Cherry Sts., Toronto, Ontario.

21544—March 24—Approving and authorizing clearance at G.T.R turntable at St. Thomas, Ont.

21545—March 24—Authorizing G.T.R. to reconstruct Bridge No. 328, carrying its railway across Vanstone's Pond at mileage 143.14, 6th Dist., near Lansdowne, Ontario.

21546—March 23—Approving revised location of G.T.P. Branch Lines Co.'s Regina-Moose Jaw Branch through north half of Sec. 28-17-20, W. 2 M., mileage 2.10 to 3.11, Dist. Regina, Sask.

21547—March 25—Authorizing G.T.R. to operate trains over interlocking plant at Paris Jct., Ont., without their first being brought to a stop.

21548—March 23—Approving location C.P.R. station at Denhart, on its Bassano Easterly Branch Line, in N.E. ¼, Sec. 2-20-11, W. 4 M., Alberta.

21549—March 24—Directing that G.T.R. submit for approval of Board a plan showing location of new station at Summerstown Station, Ont.; that Co. provide adequate and suitable accommodation for receiving, loading, unloading and delivering of all traffic offered for carriage upon its Rly., at Summerstown; erection of station be completed and facilities be provided by July 1st, 1914.

21550—March 24—Authorizing city of Fort William to construct, at its own expense, highway crossing over G.T.P. Ry., where Stanley Ave. would intersect said railway, Fort William, Ont.

21551—March 24—Directing C.P.R. to reappoint station agent at Beverly Station, Sask.

21552—March 25—Authorizing Board of Highway Commissioners for Government of Sask., at its own expense, to construct highway crossing over C.N.R. in N.W. ¼, Sec. 31-26-13, W. 3 M., at west end of station grounds at Forgan, Sask.

21553—March 21—Amending Order No. 21332, dated February 4, 1914, by exempting from operation of the Order the land of H. Strong, Tp. Bathurst, Co. Lanark, Ont., subject to certain conditions, that Rly. Co. (C.P.R.) erect return fences and cattle guards on H. Strong's farm crossing.

21554—March 24—Authorizing C.P.R. to construct spur for city of Moose Jaw, Sask., on Subdivision Lots 27, 28, 29 and 30, Block 127, city of Moose Jaw, Sask.

21555—March 26—Authorizing the Cedars Rapids Manufacturing and Power Co. of Montreal to take additional land for its right of way for its transmission line across certain lots in the parish of St. Joseph de Soulanges, Co. Soulanges, Province of Quebec.

21556—March 24—Authorizing the C.P.R. to construct road diversion in Sec. 34, Twp. 20, Rge. 7, W. 2 M., Sask., at mileage 100.3, McAuley Subdivision of its line of railway.

21557—March 25—Authorizing the Niagara, St. Catharines and Toronto Ry. to construct, maintain and operate a siding for the Electric Steel and Metals Co., Limited, in the town of Welland, Ont., and to construct said spur along Lincoln Street and across Denistoun Street.

21558—March 26—Authorizing the Toronto, Hamilton and Buffalo Ry. to construct, maintain and operate a temporary branch line of railway, or spur, on Lot 2, in the Broken Front Concession of the said Twp. of Barton, extending from a point marked "O-H.B." on the T.H. and B. branch line of railway serving the National Steel Car Co., Limited, and running thence northeasterly through the lands of the said National Steel Car Co., into and across the lands of Sir H. M. Pellatt, to and into the lands of the Dominion Power and Transmission Co., to a point marked "9-50 end track;" said branch line to be constructed and completed within six months from date of this Order.

21559—March 27—Extending the time within which the Campbellford, Lake Ontario and Western Ry. may use the crossing of the C.N.R. in the east half of Lot 12, Con. 4, Twp. Scarborough, Co. York, Ont., at mileage 0.35, until March 27th, 1915.

21560—March 26—Refusing application of the town of Forward for order directing C.P.R. to move its station; ordering C.P.R. to construct a spur at Forward, Sask.; commencing at a point on its Ry. just east of the distant semaphore and running eastwardly for a distance of five hundred feet; said spur to be constructed and completed by June 1st, 1914.

21561—March 31—Certifying that correction of book of reference endorsed on C.P.R. plan dated June 24th, 1911, to show Henry L. Auger as owner of portions of lands lying between stations 70-99 and 73-25 and between 73-91 and 75-16 respectively, instead of C.P.R. Co., is allowed.

21562—March 27—Authorizing C.P.R. to construct extension to spur for Hyde and Sons, Limited, in city of Outremont, Que.

21563—March 27—Authorizing G.T.R. to construct siding, subject to terms and conditions in by-law No. 74 with exception of condition No. 7, commencing at a point on 19th Dist., of its Rly. south of Allanburg Station, thence in a southwesterly direction upon, along and across Water Street (not opened). in village of Allanburg, Co. Thorold, Ontario.

21564—March 30—Authorizing Board Highway Commrs., for Government of Saskatchewan to construct, subject to terms of consent on behalf of C.N.R., at its own expense, highway over right of way and tracks of C.N.R. in N.E. ¼, Sec. 8-48-25, W. 3 M.

COMMERCIAL DESIGNING OF STRUCTURES

MONEY CONSIDERATION NEXT IN IMPORTANCE TO THE GOVERNING FACTOR OF STRENGTH—SOME INSTANCES OF EXPENSIVE DESIGNING—A CRITICAL ANALYSIS OF COSTS.

By DANIEL J. HAUER
Consulting Engineer and Construction Economist

THE highest function of an engineer is that of designing. A man with limited ability and education may be able to carry out the plans and designs of another, but the broader and higher the education of an engineer, together with a well-balanced experience, the greater should be his ability in designing.

The world knows much of the structures and appliance of such greater designers and inventors as Sir Christopher Wren, Watt, Stevenson, Bartboldi, Eiffel, Roebling and Westinghouse, although it knows little of the men who carried out their designs. The names of the greater designers of engineering structures and machines live in the history of the world, but to few of those who carry out designs, i.e., the builders, does this apply. Goethals, of Panama, is an illustrious exception.

In all designing there is need for care and accuracy. The lives and welfare of many people are dependent upon the work of designers. There should be two standards of designing in every country. One should be for work done by the general government, in which the standard for excellence should be of the highest, represented by strength and artistic lines and finish.

Cost and service should not be the governing factors. Representative structures of this kind abound in the old world, in the many cathedrals, palaces, memorial arches, parks and boulevards, and in America the number of similar magnificent structures is increasing.

The second standard should be for commercial structures, for which the first consideration should be strength, the second cost and service or utility, and the last, art. However, art should not be sacrificed for a few cents, or when an artistic finish can be had for the same money for which an unsightly structure can be reared. In all commercial designing, all governing factors should give way to cost, except that of strength. This cost is not only that of construction, but also of service and operation, for it is manifestly wrong to design a structure for cheapness of construction that will not serve its purpose, or will cause a high cost for operation.

It is to be regretted that there are many instances occurring annually of engineers sacrificing strength for money considerations. Only a few years ago the sad spectacle was recalled in a paper before a technical society, of an engineer acknowledging that owing to money considerations, he had designed an important structure with such a low factor of safety that it had failed, wrecking very valuable property and causing heavy loss of life.

Buildings under construction fail, dams are washed out and many other engineering structures go down owing to faulty designs, insufficient strength being given to the designs through errors of judgment, lack of knowledge of designing, and sometimes to incomplete surface and sub-surface surveys, and data upon which to base the designs.

Such things are either directly or indirectly the fault of engineers. Directly, when they can control their work, or they undertake designing for which they are not fitted, and indirectly, when they cannot control their work, by not being furnished ample funds and time for surveys or are interfered with by governing boards and bodies, and they do not protest against such restrictions. Engineers under such circumstances should put their protests in writing and if conditions are not then remedied, they should refuse to go on with the work. Engineers should remember that in continuing under these circumstances, they are no longer living up to the high standards of their profession, but are injuring both their profession and themselves, for they suffer in reputation, while others escape all odium.

Beyond these considerations, money and service should be the guide of all commercial designing. Many designs will serve the same purpose, but some are much more expensive from either a construction or operation standpoint than others.

Some years ago, in designing some pile bridges for a railroad the plan called for a tenon on top of the piles to be mortised into the caps. This added to the cost of construction and of renewals, while it did not add to the strength. Drift bolts and lag screws formed the ordinary method and proved satisfactory for this purpose. Mortise and tenon work is used in frame structures, but owing to the extra cost the tendency is to substitute cheaper joints that will give the same strength and longer service, as a mortise is a hole to catch rain water and start decay.

A revolving drawbridge of the bob-tail type, i.e., with but a single span, was designed by an engineer, and to counterbalance the weight of the span, he designed heavy steel members on the end opposite to the span, as in the space provided for concrete he could not get enough of that material to serve as a counterbalance. A more experienced engineer cut out of his design several

tons of high-priced structural steel, and substituted a like amount of scrap iron and steel to be mixed with the concrete, at a cost of only a few cents per pound. The utility of the structure was the same, the cost of construction much less.

A mechanical engineer designed an elaborate and expensive, but an ingenious and economical, set of cranes and devices for charging a reheating furnace and serving a steam hammer with ingots of a certain kind. It was afterwards found that it was not possible to work these ingots with that hammer. Here was a waste of money due to designing without having complete knowledge of the work in question. A few dollars spent on experimenting with the ingots in question with this hammer, would have prevented this error.

More than a decade ago a bridge being built in Canada failed owing to a pier sinking in the river as soon as the false-work was removed, owing to incomplete sub-surface surveys. This was a great waste of money due to faulty design of the foundation, based upon insufficient knowledge of the soil under it. Additional time and money spent in exploration would have prevented the failure.

Failure during construction does not always mean poor design. A few years ago an engineer had to build more than a mile of shore protection along a bay. He designed four types of walls and decided upon a design of concrete protection that was 50% cheaper than any of his other designs. He was severely criticized because about 200 feet of his shore protection failed, while being constructed under adverse conditions. Yet, this slight loss amounted to only a few hundred dollars, while he had saved more than $10,000 by the accepted design.

When the entire structure was finished it had ample strength to serve every purpose, and has proven this by some years of use.

Sewers are designed with many shapes, some of them extremely fantastic and expensive to build. Even with steel forms that are used over and over again for concrete sewers, some shapes make the cost of construction excessive. An odd shape does not add to the value of a sewer, but rather detracts from it, for the shape of the sewer should be designed for strength, available head room, and for the easiest flow of the sewage through it according to the gradient. This is also the case with conduits and aqueducts. If these considerations are followed in designing, then the costs are not likely to be excessive. When one considers the thousand miles of sewers that are needed in America, the need of an economical design of conduit is at once apparent.

Because concrete can be moulded into almost any shape, is not sufficient reason for making odd and expensive designs, not only in sewers, but likewise in any concrete structure. A railroad company asked for bids upon a number of concrete structures to replace stone masonry. The engineer had designed these concrete structures just as though they were built of stone, i.e., the wing walls had steps in them and the back of the walls and abutments had a series of steps and offsets varying from two inches to a foot, all of which meant extra costs for form work, adding nothing to the strength, as the same purpose would be served by a batter to the walls.

During the past year the writer made a visit to more than a dozen concrete bridges under construction, with a view to making economic studies of the work. It was quite surprising to note that only one engineer in designing his bridges had taken into consideration the methods of construction, and without sacrificing strength, had made his design so that thousands of dollars were being saved in construction, especially in forms. The centering timber used on one job had previously been used on three other bridges, to the superintendent's knowledge, and he stated that it was not new then. The cost of forms for concrete is always a heavy item. When their cost can be reduced it is the duty of the engineer to so design his structures.

This does not mean that graceful lines and architectural beauty should be excluded from the design. There can be ornamental panels, balustrades, columns and arches, as these structures are not only meant for service but to beautify. On the other hand, it is a waste of money to design and build ornamental panels, when they are to be covered over with vines, or the structures are so situated that they cannot be seen. A city once paid to have some bridges in a park made of ornamental design, only to allow their consulting landscape gardener to cover them with ivy. The ivy-covered bridges were pretty, but the costly ornamental panels were hidden, leaving only the graceful lines of the concrete bridges to be seen.

In designing structures the service of sewers, bridges and similar structures, is simple, i.e., they are for a single purpose. But it is not so with buildings and other edifices. Here the engineer must consider many things as regard to service, the problems being more complex. First of all, the purpose for which the building is to be used, should govern the lighting of the structure. The error in most cases is that of not having enough light, or having it enter at the wrong place or angle. Space that is too valuable may be given over to lighting, without obtaining the proper effect. At times the error may be to make the light too intense. These things apply to both sun and artificial light. A building to be used as a warehouse for storing goods does not present a difficult problem in lighting, but a school building, library, public hall, department store and factory gives the designer a very complex problem, and the success of the entire project may depend entirely on the lighting.

Money can easily be wasted in such cases. Few designing engineers and architects have given this subject study enough to solve such problems unaided, so they should call upon the services of expert lighting engineers, whose business is that of lighting alone.

In designing buildings for manufacturing, the various steps of the work to be done should be considered. The work should be planned first, and then the building designed to suit. Thus floors are generally built on the same level, while if different levels are used, chutes may carry the material from one machine to another by gravity, saving either machinery or the transferring by hand. The arrangement of rooms and floor space for machines should be in accordance with the sequence of the work so that material will not be handled unnecessarily. These arrangements should also be made in connection with the lighting system, for ample light means quicker and better work.

Store rooms for raw materials should be arranged at the place from which the material is to be worked up, and storage places for the finished products should be at the opposite end. This seems simple, yet it is a detail that is often overlooked, these store rooms being located with a view of easy handling, rather than for economical handling within the plant.

A few years ago a large manufacturing plant was to be rebuilt. The owners first employed a firm of economists to make a study of their methods of manufacturing and to devise a more economical method. This done, the engineer and architect drew up plans under the supervision of the economists. Many things were designed different from the ordinary standards and even a lighting engineer was employed. The result was that operating costs were cut nearly 25%, while the cost of building was reduced 10%. All waste room was cut out, and few later alterations had to be made.

This was in contrast to a large saw mill that was destroyed by fire and rebuilt last year on the same general plan as before. All the finished product has to be carried the entire length of the mill to be placed in the storage yard.

These examples illustrate how many engineers overlook the service feature of their structures, and how money is thus wasted in building and in operation. Both the old and the young man engaged in designing will do well to consider these important things.

MUSKOKA RIVER STORAGE.

The sixth annual report of the Hydro-Electric Power Commission contains some information on the watershed of the north branch of the Muskoka River, lying in the districts of Muskoka, Parry Sound, and Nipissing, and comprising an area of about 560 sq. mi. above Port Sydney.

The report, which has just been issued, is for the year 1913. One of the important chapters it contains is that devoted to the hydraulic investigations that have been carried out during the year. The data on stream flow and storage possibilities of various rivers in the province are steadily accumulating, and represent the acquirement of hitherto unavailable knowledge that is most important in the development of the water powers of Ontario. F. A. Gaby, B.A.Sc., is chief engineer to the commission, while H. G. Acres, B.A.Sc., and T. H. Hogg, B.A.Sc., are hydraulic engineer and assistant hydraulic engineer respectively. The following data relates to their work up to October 31st, 1913, on one of the many rivers under investigation, and outlines a projected scheme of improvement whereby storage and complete regulation of flow may be effected:

General Conditions.—Until recently, the paramount industry in the territory mentioned above has been lumbering, and for many years the north branch has been used for the transportation of saw-logs. Under ordinary conditions, log-driving seriously hampers power development, but a peculiar feature of the situation as regards the Muskoka River is that injury is now being caused not through the activity of the lumbermen, but through the cessation of their operations in the upper watershed. This is due to the nature and location of the lake areas.

In the lower portion of the watershed is a group of four large lakes, all but one practically on the same level. In the upper watershed is a large number of small lakes, which have in the past been controlled by lumbermen's dams. When lumbering operations were at their height, large quantities of water were held in these upper lakes, and they were flushed out more or less in succession in bringing drives down the main river and out of tributary streams. The water thus liberated discharged into the group of larger lakes above mentioned, and through their capacity for storage they reduced and equalized the various flood peaks, and discharged them more gradually into the lower river. As the lumbering industry waned, the quantity of water stored in the upper lakes was reduced, and the dams began to suffer from lack of maintenance, the result being that an increasing proportion of the spring run-off discharged naturally into the lower basin, and drained off in the early part of the summer.

The result has been that, while power has been developed upon the river on the basis of a minimum flow which existed 10 years ago, the minimum flow during the last three or four years has dropped as low as 120 sec.-ft. at High Falls, or less than half the flow which was ordinarily supposed to obtain 10 years previous. A large part of the capital invested has on this account become unproductive, and long and frequent periods of inadequate service have caused much trouble and inconvenience, as well as a serious loss of revenue.

The object of the investigation is to determine to what extent artificial storage can be used to improve present conditions.

The oldest established industry in the Muskoka River watershed is lumbering, but owing to the fact that practically all the pine has been cut, the waters of the north branch are now very little used for driving purposes, and in two or three years' time, the use of the waters for this purpose will practically cease.

The navigation interests are confined almost exclusively to the handling of local tourist traffic and through tourist traffic to the Lake of Bays. Open navigation exists between Huntsville and Peninsula Lake, and connection with Mary Lake is made by means of a lock.

Several passenger steamers are kept in commission during the tourist season. The largest boat on the Huntsville-Portage route is 125 ft. long, 22 ft. beam and has a maximum draft of about 7 ft. The largest boat on the Mary Lake route has a maximum draft of 6 ft., and has a length and beam specially adjusted for the dimensions of the lock.

As to the commercial use which may in future be made of these waters for navigation purposes, it would seem that the limit of their utility would be the bearing of a tourist traffic not very greatly in excess of that now existing. This opinion may be justified on the following grounds:

(1) That the cutting out of the pine timber has destroyed any lake commerce that has previously existed in connection with the lumber industry.

(2) That the desertion of farms in the townships bordering on these lakes indicates that they will be used less in the future, in connection with the commercial needs of agriculture, than they have been in the past.

(3) That the continual opening up of new tourist districts by the railways will tend to check any abnormal expansion of the tourist traffic out of Huntsville.

It will be assumed, therefore, that the requirements of navigation will be adequately met by providing for the permanent accommodation of boats similar to those now operating.

The minimum depth of channel between Huntsville and the Portage will, therefore, be 8 ft., and 7 ft. between Fairy Lake and Port Sydney.

Power.—In the year 1892, the town of Bracebridge put its No. 1 hydraulic plant in operation in the Muskoka River, a 16-ft. head being developed for lighting load

only. This plant is now used exclusively for municipal pumping. In 1901, plant No. 2 was built, and a 250-kw. unit installed. In 1908 it was found necessary to add a 300-kw. unit. In 1909, the growing demand for power led to the building of No. 3 plant at Wilson's Falls. This site is now developed to full capacity, 600 kw. being installed. At the present time, the town has over 2,000 h.p. of wheel capacity installed, and a continuous market demand of 1,500 to 1,800 h.p. Under the low water conditions which have obtained during recent years, about 25 per cent. only of this installed capacity has been capable of use, and for weeks at a time the town has been obliged to carry a commercial load of 1,800 h.p. with a maximum plant output of about 550 h.p.

It is quite evident that the continued occurrence of these periods of power shortage would ultimately ruin the municipal system, as manufacturers would be forced to install a more dependable type of motive power.

In view of the above, it is unnecessary to emphasize the urgent need of improving the flow characteristics of the north branch of the Muskoka River. The obvious means of effecting such improvement is by the storage of surplus run-off in the navigable lakes, or in the smaller lakes of the upper watershed.

Storage Possibilities.—The choice of initial storage development lies between the group of four navigable lakes above Port Sydney, and a larger number of very much smaller lakes on the upper watershed above Lake Vernon.

As regards the latter, the complete development of the larger lakes would provide approximately 60,000 acre-ft. of storage. To obtain this, it would be necessary to repair and maintain seven to ten timber dams. Owing to the small storage capacity of the individual basins, more or less constant attention would be necessary for proper operation, and the inaccessible location of most of these basins would be detrimental to operation, both as regards cost and efficiency.

Another disadvantage consists in the fact that stored water from the upper system of lakes must pass through and be partially absorbed by the large lakes above Port Sydney. The influence of wind and temperature on these lakes will make it impossible to foretell with any degree of accuracy what effect the flushing out of a basin would have on the regimen of the lower river, or in what time the effect would become noticeable.

The obvious solution of this latter difficulty is, of course, to use the navigable lakes as auxiliary storage basins. This has actually been done through the agency of the government dam at Port Sydney.

Having established the fact that the navigable lakes must in any case be used to some extent in connection with any storage scheme that may be devised, the question arises as to whether the storage of these lakes could be developed sufficiently to dispense altogether, or in part, with the necessity of developing the upper system.

The combined area of the four lakes involved is such that about 10,000 acre-ft. of storage is available for each foot in rise. The importance of obtaining the maximum possible range of variation in level is therefore evident, and the whole point at issue is to determine a range of variation which will, on the one hand, cause no extensive damage by flooding, and, on the other, permit minimum navigable levels to be permanently maintained.

Results of Surveys.—The investigations of this problem necessitated the making of surveys covering a new site for a dam at Port Sydney; flood contours around Mary Lake; surveys, with soundings, of various channels. These surveys were of service in reaching certain conclusions which may be summarized as follows:—

(1) That the maximum regulated level of Mary Lake could be held 3 ft. above the ice level which obtained at the time of the survey, without causing undue damage.

(2) That the maximum regulated level above the lock should be held at, or slightly below, high-water level, corresponding to about 8.5 ft. on the upper sill of the present lock.

(3) That a 3-ft. variation of level above the lock, during the navigation season, will not injuriously affect navigation or riparian owners.

(4) That a 4-ft. variation of level below the lock during the navigation season will not injuriously affect navigation, and will not cause serious injury to riparian owners.

New Construction and Improvements.—The existing dam at Port Sydney is a wooden structure built by the Provincial Government for maintaining navigation between Port Sydney and the lock. This dam now requires to be replaced, and, in the interests of economy and efficiency, a permanent structure should be built. The lock between Mary and Fairy lakes is in a dilapidated condition, as is also the dam. The useful life of the dam might be prolonged by extensive repairs, but the lock requires to be entirely rebuilt. All new construction at this point, whether lock or dam, or both, should be permanent.

In the narrow channels between the lakes, the backwash of the boats cuts away the banks, and the consequent silting up of the navigable channels necessitates frequent dredging. This silting action could be effectively stopped by pile sheeting the exposed sections. The whole length of the channel between Fairy and Peninsula lakes should be treated in this way, and also certain portions of the channel between the lock and Mary Lake.

All of the above new construction is required in the interests of navigation, and any additional features of design in connection with these structures, which might be necessary in order to adapt them for storage regulation, would be insignificant from a cost standpoint. The surveys also indicated that the storage capacity of the lakes above Port Sydney could be economically increased by deepening some of the connecting channels between the lakes.

Details of General Scheme.—The dam at Port Sydney is to be designed so as to enable the levels of Mary Lake to be held between El. 23 and El. 27 during the navigation season, and to allow for an additional drop of two feet during the fall and winter. The bottom of the navigable channel between Mary Lake and the lock has been set at El. 16. A small amount of excavation may be necessary through the sandbar at the mouth of the river. Some soft dredging will also be required just below the lock.

At the lock, it is proposed to drop the lower guard sill to El. 15, and the mitre sill to El. 14. The upper guard sill is dropped to El. 23, and the mitre sill to El. 22. There will thus be 8 ft. of water on the lock sills under the minimum projected summer level.

With a tight permanent dam at Port Sydney, a permanent dam at the lock is not absolutely necessary, and present requirements will be met if the latter is repaired and alterations made which will enable it to hold the level above the lock within the extreme limits of variation, El. 34 max., and El. 29 min.

The general scheme provides for a navigable channel 60 ft. wide, with a minimum depth of 7 ft., between Fairy Lake and Port Sydney, with 8 ft. minimum on the guard sills of the lock, so that an 8-ft. channel could be provided in the future by dredging.

The adoption of the scheme would make 3 ft. of draft available in summer, and 2 ft. additional in winter, upon Vernon, Fairy and Peninsula lakes, making in all 5 ft. of draft available. Under similar conditions, 4 ft. of draft will be available on Mary Lake during the navigation season, and 2 ft. additional in the winter, making 6 ft. available in all. The combined area of Vernon, Fairy and Peninsula Lakes, is about 7,600 acres. The area of Mary Lake is about 2,600 acres. On the basis of the above figures for area and storage draft, the four lakes would provide 32,800 acre-feet of storage during the navigation season. The benefit to be derived from this volume of storage will be proportional to the length of the low water season, which will vary from year to year. The continuous supply from storage alone, for seasons of various lengths, would be as follows:—

107 days	from July 17 to Oct. 31	 155	second-feet.
92	" Aug. 1 to Oct. 31	 179	"
76	" Aug. 1 to Oct. 15	 210	"
61	" Aug. 1 to Oct. 1	 271	"

Under the worst possible conditions that could be imagined the watershed of the Muskoka River above Port Sydney should produce a natural minimum run-off of one-tenth of a second-foot per square mile of watershed. This would mean a natural low-water discharge of 56 sec.-ft. at Port Sydney.

If the flow from storage under various conditions be superimposed upon this natural discharge, the figures given above will become 211, 235, 274 and 327 sec.-ft. respectively. These latter figures fairly cover the range of benefit to be derived from the utilization, during the navigation season, of 32,800 acre-feet of storage on Vernon, Fairy, Peninsula and Mary lakes.

As to winter storage, it has been assumed that 2 ft. additional could be drawn off the lakes after the close of navigation. Assuming no fall replenishment, there would be 20,200 acre-feet of storage available, to meet low-water conditions during the winter. Two months' use of winter storage would probably cover the worst condition; say, from January 15 to March 15. Over this period, the above specified volume of storage would provide a continuous flow of 169 sec.-ft., which, superimposed upon a natural minimum of 56 sec.-ft., would mean a continuous supply of 225 sec.-ft. under the worst winter conditions to be anticipated.

The outstanding points of advantage in the above scheme are the greater accessibility of the works, and the vastly greater degree of precision with which the flow can be regulated, if properly designed works are placed at the lock and at Port Sydney. The facilities thus afforded for efficient regulation would more than offset any advantage the upper lakes might have as regards aggregate storage capacity.

The complete development of the storage of the lower lakes will also allow the storage of the upper lakes to be properly utilized at very small cost, should the necessity arise. It would simply be necessary, in this case, to keep the wooden dams in a fair state of repair, and to flush out the various small lakes in rotation whenever the stage of the lower lakes was such as to permit the reception of the additional supply.

The cost of operating and maintaining the upper system under such circumstances would be comparatively insignificant.

In conclusion it may be noted that the development of artificial storage for power purposes on navigable lakes is not by any means a new idea. The navigable lakes on the Trent and Rideau systems have been used for storage purposes for years, and the range of level variation which obtains on the navigable lakes included in both of these systems is much greater than that contemplated in the case under discussion. Furthermore, in the case of the Trent Canal a through navigation route is involved, where the interests of shipping will be of vastly greater importance as compared to those of power than they can ever hope to be on the lakes above Port Sydney.

CYANAMID FACTORY AT NIAGARA FALLS.

THE problem of artificially fixing atmospheric nitrogen and combining it in suitable forms for plant food has been a difficult one for scientists and one which has had their serious thought and attention for many years. In 1895 two German scientists, Drs. Frank and Caro, found that when nitrogen gas is conducted through a hot mass of calcium carbide there is produced a compound known as Cyanamid, very rich in nitrogen.

This form of combined nitrogen was found to possess particular value as a fertilizer and its use for this purpose has developed an enormous industry. Cyanamid factories have been established all over the world. One of the largest of these is located at Niagara Falls, Ontario,

New Addition to the Plant, at Present in the Process of Construction.

where large quantities of electricity, required in this industry, can be obtained at low cost.

The American Cyanamid Company owns the sole right to manufacture and sell Cyanamid in America. Its factories at Niagara Falls began operations on January 1st, 1910. The original plant had an output of 12,000 tons a year, but this was increased during 1912 to approximately 32,000 tons a year and further extensions are under way to give an annual output of 64,000 tons.

From the very commencement of operations at Niagara Falls it was clear that a plant capable of producing 12,000 tons per annum was totally unable to meet the market requirements, but a policy was adopted to thoroughly prove the commercial practicability of, and demand for cyanamid before building a large plant.

After two years' experience they realized that the product could be looked upon as an undoubted commercial success. Methods of manufacture have been simplified and cheapened, and it is now necessary to double the existing plant in order to cope with the increasing orders.

View of Complete Plant, Showing Lime en route to Kiln.

Nitrogen is the most important of the plant foods. It is usually the first element to become deficient in cultivated soils, yet when good forms and proper amounts are furnished, crops respond to it with a more direct and immediate effect than to application of phosphate and potash.

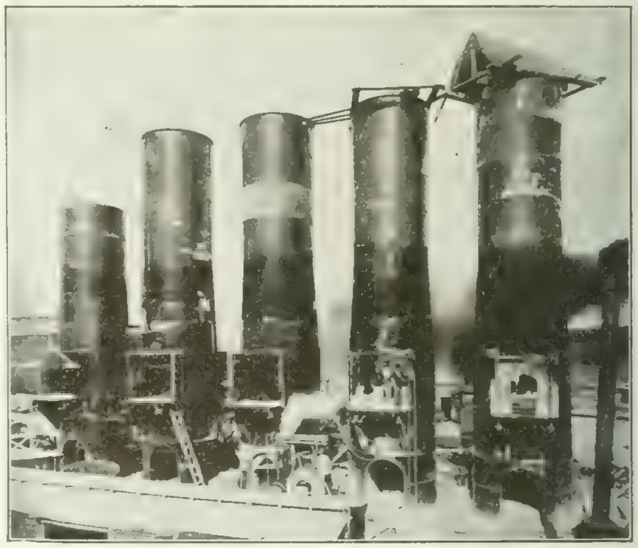
All the combined nitrogen now in existence on the earth's surface came from the atmosphere at some time. Previous to the discovery of cyanamid the only practical means of directly fixing atmospheric nitrogen was by the action of bacteria. These bacteria, themselves living on plants or plant refuse, take nitrogen from the air and combine it into chemical forms that plants can absorb. If plants were not removed, but were left to decay where they grow, the fertility of the soil would probably never decrease. When crops are removed, however, not only is the nitrogen carried away but also the plant matter on which the bacteria feed. Then, in order to maintain fertility, it is necessary to restore combined nitrogen to the soil from other sources.

Cyanamid is a bluish-black, odorless, powdered material. It contains from 18 to 20% ammonia, about 12% carbon, or lamp-black, and the equivalent of about 70 pounds of slaked lime. The material is shipped in burlap bags and can be stored indefinitely.

Cyanamid nitrogen is readily soluble. Ninety-six per cent. will dissolve out in cold water and is therefore available as plant food. On contact with the soil it reacts quickly and forms first the organic compound, urea, and then changes into the form of double ammonium compounds. These compounds are not leached or washed out of the soil, but are made available to crops by bacterial action and the solvent effects of plant roots. This action insures a slow, steady supply of nitrogen that has the advantage of not overfeeding crops a few weeks and then starving them, but of supplying this element throughout their principal period of growth. Since the soil duration of cyanamid nitrogen is from 60 to 80 days, crops are not fed when they should be maturing, and therefore ripen earlier and more uniformly.

Every 100 pounds of cyanamid contains the equivalent of about 70 pounds of slacked lime, which adds considerably to its value as a fertilizer. This line costs the farmer nothing—cyanamid is sold on the basis of the ammonia it contains as determined by analysis.

The beneficial action of lime is well known. Briefly its advantages are as follows: (1) It corrects soil acidity and produces conditions favorable for the growth and



Kiln Shells Being Erected and Fire Clay Lining Commenced.

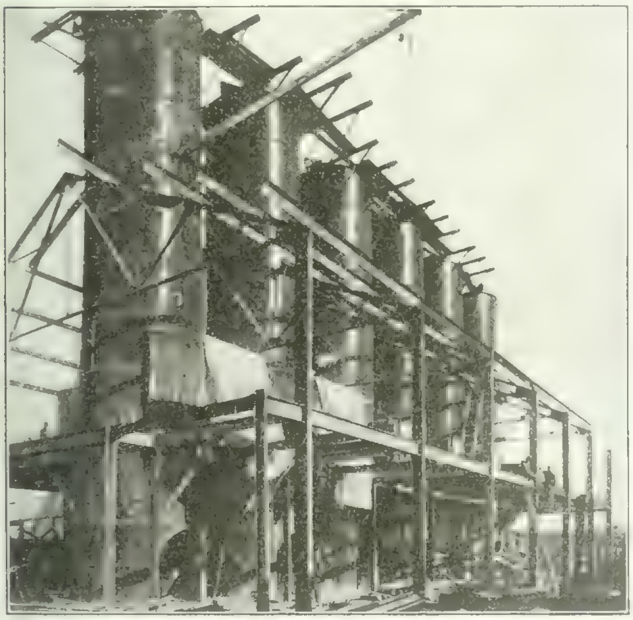
activity of nitrifying bacteria, which supply plants with much combined nitrogen. These bacteria are destroyed by acid conditions, but thrive in limed soils. (2) Lime

General View of Plant.

hastens the decomposition of waste products used as manures. (3) It destroys many injurious insects and soil diseases. (4) It makes available the phosphoric acid and potash often held too firmly in combination by some soils. (5) It improves the mechanical condition of all soils, making clay more porous and sand more retentive.

A regular application of cyanamid to soil in good condition should ordinarily neutralize the acids occuring therein. The ease with which the lime content of the soil is kept at a desired point makes this fertilizer especially valuable. Many other fertilizers tend to increase soil acidity until finally heavy liming is necessary. The yearly addition of lime as a part of the cyanamid fertilizer involves no extra expenditure of time, labor or money.

The manufacture of cyanamid depends upon the chemical fact that calcium carbide at a high heat combines with atmospheric nitrogen and forms calcium cyanamid. Calcium carbide is made by fusing together



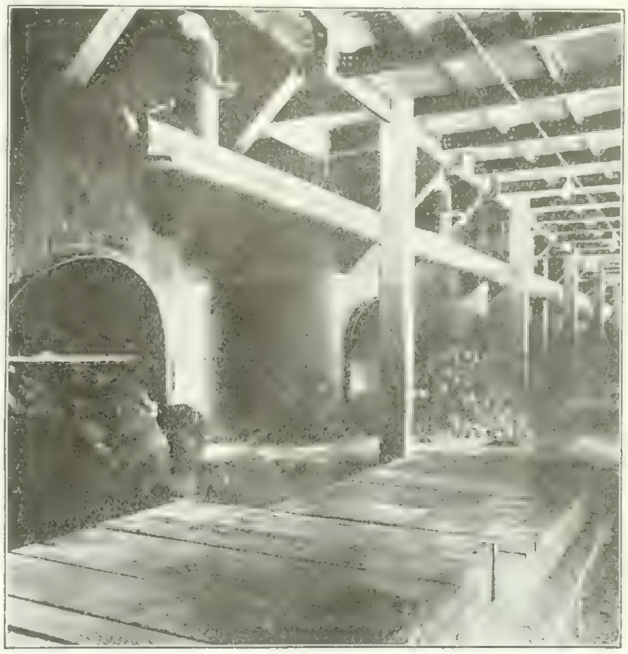
Kiln Shells Completed and Piping Being Installed.

lime and coke in an electric furnace. The carbide is placed in the ovens heated by electricity to a white heat and nitrogen is led into the ovens and is there combined with the carbide, forming calcium cyanamid. After cooling, this material is ground, treated with water and put through a mechanical finishing process.

It will readily be seen that for economical production of cyanamid the plant must be located where electricity can be secured at the lowest possible cost.

Before the installation of the cyanamid plant at Niagara Falls another matter of importance was to determine the kind of reducing gas to be used in the preparation of the nitrogen. After careful consideration a coal gas plant was decided upon as the entire output of coke could be used in the manufacture of calcium carbide and the coal gas gave the greatest amount of carbon content for use in the nitrogen ovens.

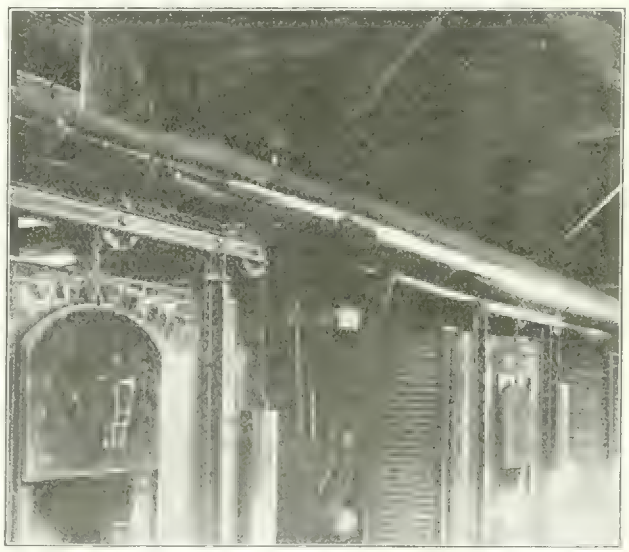
The nitrogen ovens consist of a series of vertical retorts heated by small individual furnaces. Copper oxide is placed in these retorts, and when the retorts are brought to the proper temperature air is forced through the retorts and the oxygen of the air combined with the copper and cupric oxide leaving the nitrogen free. The air is then shut off and as the oxide has gradually become foul during this cycle coal is then passed through the retort, which acts as a revivifier for the reducing agent. The nitrogen is then forced through pipes into the electric



Lime Discharge Floor, Showing Handling Arrangement.

furnaces where it combines with the calcium carbide and forms calcium cyanamid, or commercial cyanamid.

The lime plant for the manufacture of lime to be used in the cyanamid plant was designed and installed by the



Arrangement of Charging Doors of Kilns.

Improved Equipment Company. The original plant consisted of six Doherty-Eldred lime kilns equipped with the Eldred process and induced draft.

[illegible] their usefulness has not as yet been fully demonstrated.

SOME GOOD ROADS, THEIR CONSTRUCTION AND MAINTENANCE.

By Robert C. Muir, C.E.,
Mackenzie, Mann and Company, Toronto.

(Concluded from last week's issue.)

Brick Pavements.—Brick pavements, though used extensively in Europe for over 100 years, have only quite recently come to be used in this continent, the first being laid some 20 years or so ago. At first failures were numerous, these failures being due to poor foundation or the quality of brick. In Europe this form of pavement has proved highly satisfactory, and found in many places to be superior to stone blocks. Rotterdam and Amsterdam being two cities almost entirely paved with brick, here the brick for extra heavy traffic is imported from England and local brick used for light traffic.

The advantage of brick pavements are:—

(1) Easily cleaned.
(2) Easily repaired.
(3) Makes traction easy.
(4) Good foothold for horses.
(5) Durable under all kinds of traffic, granted foundations are good.
(6) Little dust and no mud.

The chief defects are: (1) The lack of uniformity in the brick; (2) noise.

The clay that the bricks are made from must be free from lime; thorough grinding and mixing of clay is essential, so as to have no lumps on the brick. A solid foundation is here again absolutely necessary, a weak foundation being often the cause of failure in all pavements. The foundation in every case should be formed of concrete (1:4) 5 inches thick.

Methods of Construction of Brick Pavements.—*Pavement on Brick Foundation.*—The roadbed should be graded to 11 in. below finished surface, then rolled until thoroughly consolidated. On this bed should be spread a layer of ashes to a depth of 3 in., then rolled. A covering of sand is then applied of sufficient thickness to form a cushion to the proper shape for receiving the bottom or foundation course of brick. This being satisfactory, place the foundation course of brick, long side parallel with curb, laid close and all joints broken. Dry sand should be spread over this and thoroughly brushed to fill all crevices.

Another layer of sand 1 in. thick is laid on to form cushion for top course of brick. This course will then be laid with longest edge surface across street at right angles to curb, laying brick as close as possible and breaking joints, no half-bricks being used unless where necessary to break joints. The surface should be then covered with sand, well brushed, and then rolled. The bricks used to be of the best quality, uniform and regular in shape and free from cracks.

Brick Pavement on Concrete Foundation and Grouted with Pitch.—The roadbed should be rolled and thoroughly consolidated and prepared to receive a layer of ashes 3 in. thick. The concrete foundation is then laid, depth varying according to traffic (5 in. is reckoned to be sufficient for medium traffic). The surface is to be made parallel with the finished surface of the pavement by floating the concrete surface over with cement and using straight-edge. Traffic should be kept off while concrete is setting, and brick should not be laid thereon for at least 4 days. When foundation is ready to receive brick lay a cushion of sand 2 in. thick. On this lay bricks on edge at right angles to curb, as close as possible, joints to be broken and then rolled with a 5-ton roller. The bricks having been rolled to perfect surface, the crevices are then filled with pitch heated to 300° F. and entire surface covered with a depth of ¼ in.; upon this spread a layer of sand ¼ in. thick. Sand must be thrown evenly on boiling pitch, and with no delay as pavement is finished, the object being to make the pavement one solid mass, which when finished shall be watertight. The sand to be used must be clean, sharp and free from moisture.

The sizes of bricks commonly used are 8¼ x 4 x 2½ in. and 9 x 4 x 3 in.

Rumbling.—Rumbling is caused by open spaces between brick and foundation. If sand cushion is not properly compacted, the settlement will leave an opening between cushion and brick, also an opening may be caused by course of brick being forced up off sand cushion. This may be caused by the swelling of lime used as joint filler. To avoid this upheaval it is advisable to place expansion joints every 25 ft., across the street and along each curb, and filled in with pitch. This is only necessary in a case of lime or cement joint.

Tar Macadam.—This is a method used extensively in Britain within the last 4 years.

Mixing.—In making tar macadam the stones should be thoroughly dried and heated, care being taken not to overheat. While hot they should be mixed with tar in the proportion of 8 gals. per ton, and mixed by machine. Opinions differ as to size of stones for this method some holding that the stones should be from 2¼ to ¾ in., so that all crevices may be properly filled. This would be quite acceptable if it were possible to have stones so evenly mixed that a proper proportion of each grade would be evenly distributed in every square yard of roadway, but this perfect grading is seldom realized, with the result that the road surface is of unequal strength. The author adopted the system of using only one size of stone for one particular piece of work, the best results being got from stones of 2¼ in. size. The smaller stones are used for very light traffic, chippings being used as a binding coat, and also for gritting the tar-finished surface. The cost per ton of making tar macadam, including stone, tar, heating, wages and carting is $2.00. This will, of course, vary with the cost of stone, price of tar, and efficiency of tarring and drying plant.

Laying.—The existing surface is scarified, evenly raked and hard rolled; this surface to be perfectly dry. Then tarred stone is spread on 4 in. thick, if a 3-in. finished surface is required. Should weather be very hot, light rolling should be applied to get stones into position, otherwise the steam roller may push the stones in front of it, thus causing a wavy surface, which is difficult to cure. When rolled hard a small sprinkling of tarred chippings will help to bind surface. After traffic has been on road for a few weeks the surface should be carefully swept and painted with a prepared tar. This class of surfacing is perfectly satisfactory on a fairly well-bottomed road with a good subsoil. The cost of this method of surfacing for a 3-in. finished surface is 40 cents per square yard.

Another method which has given good results is by the use of "Tarmac," the aggregate of which consists of furnace slag. The slag is run in a molten state from the surface into suitable receptacles and is allowed to cool. When cool the slag is removed to a convenient location and broken to suitable sizes before being put into the crusher. Thence it is broken to the regular sizes and afterwards treated with the tar composition. The

slag having had no opportunity of absorbing moisture is, therefore, perfectly dry, no extra heating being required. The slag breaks with a rough and uneven fracture and has great holding capacity for the tar composition. It is, moreover, sufficiently porous to absorb and hold a portion of composition.

The size of stone used is 2¼ to ⅜ in. chippings. The existing road surface having been prepared, spread a 4-in. layer of 2¼-in. stone and roll until thoroughly consolidated. Upon this spread a layer of 1½-in. stone, which is rolled and consolidated, making a total thickness of 4 in. This surface is thoroughly brushed over with ⅜-in. chippings, which are also coated with tar so as to fill all crevices, then rolled to a smooth surface, this finished surface to receive a covering of chippings.

Tarmac has proved satisfactory. It is almost dustless during summer and not unduly slippery during winter.

Bituminous Tar Macadam.—Where roads are subject to fairly heavy traffic something better than ordinary tar macadam is required. The author two years ago experimented on a road having a traffic density of 160 tons per yard width per day of 24 hours, which was unsuitable for ordinary macadam. With a bituminous macadam the surface in summer is excellent, but in winter the wear is pretty heavy as the protecting surface is torn off by wheels of large motor buses, especially with a thaw after a night's frost. The tar used was to the following specifications:—

Specific gravity	1.19 at 60° F.
Freedom of water	Practically free.
Fractionation	3% at 220° C., 15% at 300° C.
Free carbon	15%.
Viscosity	30 seconds at 70° F.

This was mixed with 20 per cent. of best Mexican bitumen, and after being down a few weeks, was surface coated with the same mixture and gritted with very hard chippings. Three different qualities of stone were used: (1) a very hard, keen stone, standing a great crushing strain; (2) a good, hard stone, but not so keen as first; (3) a good, moderate stone. By experience it was found that the keen stone had not taken a proper grip of the tar, and the suction of motor wheels tended to bare this stone by removing the particles of tar, which in cold weather had become pulverized by heavy traffic; the good hard stone holding the tar better, and the moderate stone being best of all, the more expensive being no advantage.

This roadway a year later was treated with tar and bitumen, part being treated with Mexican proprietory bitumen, which did not give such good results as tar and bitumen. This is the best tarred work the author has tried for a heavy traffic road.

The cost per square yard of this method worked out as follows:—

	Cents.
*Material and mixing	41
*Laying stone and binding	9
*Surface painting	5
	55

* Including labor.

Rocmac.—This binder is a silicate-saccharate-carbonate, the foundation of which is silicate of soda, sugar and carbonate of lime. The sugar is not used for adhesive purposes, but to assist the chemical action of the silicate on the carbonate, and secondly to assist the resistance of the matrix to frost.

A matrix is formed of the mixture in the proportion of ⅓ cu. yd. of crushed limestone to 5 gal. of Rocmac solution with an addition of similar proportion of water. This is mixed similar to the making of concrete, the limestone crushed to ¼-in. gauge and dust. This matrix is applied to existing road surface to a thickness of 1 in. for a finished 3-in. coat. The stone is then spread on and rolled until the matrix comes to surface. All superfluous material is swept off and surface left clean and hard.

The advantages of Rocmac are:—

(1) Repairable in almost any kind of weather, except hard frost.

(2) Cheaper than bituminous macadam (method above described).

(3) No yearly surface painting required.

(4) Dust not so obnoxious as from tar.

(5) Good foothold for horses, not so slippery as tar macadam.

(6) When laid, frost has not injurious effect on it as upon other road surfaces.

The defects of Rocmac are:—

(1) Dustiness in summer, though after superfluous limestone has been washed off dust is greatly reduced.

(2) Hard, metallic ring.

It is claimed that the life of Rocmoc road is 3 times that of an ordinary water-bound macadam road. The cost of Rocmac was 52 cents per square yard.

The author's experience has been that with roads laid upon a clay subsoil, imperfect drainage and under a medium heavy traffic tar in any shape or form soon gave out. After careful consideration he came to the conclusion that Rocmac, though not ideal in every way, was well suited to roads under said conditions.

Asphalt Pavements.—Asphalt is by no means a modern pavement, having been used in Paris about the year 1830 and introduced in London in 1860, or thereabouts.

Foundation is of the greatest importance with asphalt pavements, a solid foundation being absolutely necessary. Asphalt is commonly laid on a concrete foundation. 5 in. thick, though good results have been obtained from old macadam and brick pavement being used as foundation, which reduces the cost considerably. Foundation must be thoroughly dry before asphalt is laid, this being a most essential point in asphalt paving. Should asphalt be laid on a damp foundation it will break up as soon as traffic goes on it. Dry weather is, therefore, necessary for the laying of asphalt.

Asphalt cement pavement is composed of the matrix and the aggregate, success depending upon the selecting of materials, mixing and laying of pavement. The matrix is a cement prepared from asphaltum. The aggregate is composed of sand and stone dust, though in many districts Portland cement has been used in place of stone dust. When Portland cement is used more asphalt cement can be used, thus making a denser mixture, which tends to lengthen the life of pavement. The matrix and aggregate are heated separately to a temperature of 280° to 300° F. and are then thoroughly mixed.

The binder, which contains 5 per cent. more cement than finished surface, is then spread on foundation 1½ in. thick and rolled until consolidated. The finished surface is now applied and spread with rakes to a thickness of 4 in., if finished thickness is to be 2 in. This surface is covered with cement to prevent the roller lifting asphalt, and rolled to a perfect and uniform shape. When the road or street is curbed, asphalt should not be laid right up to the curb, but a gutter of brick or cement formed.

General Remarks.—Planning of Streets and Roads.—(1) New main roads should [illegible] side rather than

through towns, and where existing main roads are unsatisfactory for through traffic a new road should be substituted.

(2) Grades on new roads should be as easy as possible.

(3) The radii of curves, where possible, should give an unobstructive view.

(4) Street railway tracks should be placed in the centre of roads and space left on either side for separate tracks for vehicles going in opposite directions.

(5) Main traffic roads should be designed so that tracks be provided for street cars, fast and slow traffic and standing vehicles.

(6) In fixing building lines on what may ultimately become main roads, regard should be paid to future requirements.

(7) The planning of main road communication between towns should be undertaken and some initiative should rest with a central state authority.

Causes of Wear and Deterioration of Roads.—(1) Weather has the most powerful influence on the deterioration of roads. This can be minimized by effective waterproofing.

(2) The damage of heavy motor vehicles is principally caused by the balance, the ratio between propelling power and weight, weight of unsprung portions, continuity of brake action, system of springing, type of tire, diameter of wheel, width of rim, variation of speed and other factors.

(3) Heavy motor vehicles should have wheels of large diameter, with tires of a width adapted to the axle load.

(4) Light motor traffic does not cause damage to roads bound with tar or bituminous materials.

(5) In horse-drawn vehicles diameter of wheel, width of rim, and system of shoeing horses should be considered.

Finance of Construction and Upkeep of Roads.—(1) The upkeep and improvement of all main roads should be paid out of national revenues, whether or not such roads are locally administered.

(2) All tolls on roads should be abolished, but certain vehicles, on account of weight or combined weight and speed, which cause special damage to roads, should be subject to special taxation, the proceeds to go for the construction and upkeep of roads.

Experiments have proved that the binding material on roads under heavy traffic must be of a bituminous or asphaltic nature, prepared tar not standing heavy traffic. Pavements having curb and gutter on both sides give considerable support, prevent lateral thrust and enable better initial consolidation. It is advisable that all improved road crusts should be supported by a sufficient foundation, as the tendency is that the weight, speed and intensity of traffic will increase on roads. On all bituminous or tarry surfaces it is absolutely necessary to carry out repairs whenever the necessity arises, as in the case of water-bound macadam.

Instruction in Use of Tar, Bitumen and Asphalt.—

(1) The stones must be dry and heated.

(2) Top crust never to be laid on damp foundation, and the work should be carried out in dry weather.

(3) Only a sufficient quantity of binder to be used.

(4) Tar not to be overheated; if so, has tendency to cause weakness.

(5) Heating and mixing of stones and tar to be carried out on the work; this the author considers to be a very essential point.

(6) Heavy road rollers should never be used, 3 to 5-ton rollers being preferred.

PRESENT POSITION OF THE SEWAGE DISPOSAL PROBLEM.*

By Gilbert J. Fowler, D.Sc., F.I.C.

IN 1898 the Royal Commission of Great Britain was appointed to inquire and report on the whole question of the treatment and disposal of sewage. The present Royal Commission submitted its first interim report in 1901, and its eighth report, embodying final conclusions on some of the main issues involved, was published in 1912.

In the report of 1901 the commission state that, in their opinion, it is practicable to produce by artificial processes alone effluents which will not putrefy, and which might be discharged into a stream without fear of nuisance. A great part of the Royal Commission's work has consisted in the collection of evidence and the conduct of experiments, with the object of working out the conditions of efficiency of these various processes, and of standardizing the methods employed as far as practicable, so that an authority may have a fair idea what sort of a result is likely to be obtained for a given expenditure.

The fifth report of the Royal Commission and its appendices are a mine of information in this respect, and the appointment of the commission would have been more than justified by this report alone, introducing as it does the idea of quantitative accuracy into the operations of sewage disposal.

There is no excuse now for authorities to launch out on expensive works without any preliminary study as to the character and amount of the sewage to be treated. The commission show clearly that the design and extent of the works must depend on the concentration or "strength" of the sewage. This is roughly proportionate to the water supply per head, and the amount of subsoil drainage finding its way into the sewage system. The composition of the sewage is also affected, e.g., by the quantity and character of the trade effluents discharged into the sewers, and by the proportion of water-closets to pail-closets in the district sewered, and by other factors.

In the fifth report the commission indicate in general terms the kind of works necessary to obtain a satisfactory effluent from sewage of a given character.

This, of course, does not mean that in future all that a corporation or council has to do is to take a sample or two of the sewage, have it classified as strong, medium, or weak, and order a sewage works accordingly.

The chemical and engineering conditions are in no two places alike, and in order to obtain the maximum efficiency and economy under any given set of conditions, careful thought and study on the part of the engineer and bio-chemist will always be necessary.

The author has, e.g., on more than one occasion, recently found that the sewage to be dealt with in small installations in the country is rendered much more offensive and difficult to treat by the drainings from manure heaps which are allowed to enter the sewers. A creamery in a country district may also introduce unforeseen difficulties.

Dry-Weather Flow.—The question of what really constitutes the dry-weather flow is one of great importance and some difficulty. The actual water consumption may vary from 100 to 150 gallons per head, as in New York, to, say, 10 gallons per head or less in a country town or village.

---

*Extracts from a paper read before the Liverpool Engineering Society on March 4th, 1914.

It does not quite dispose of the question to say that the strength varies in inverse proportion to volume, and therefore the provision of tanks and filters must be the same for all strengths, the rate of operation alone varying.

Obviously, as regards capacity of sewers the actual quantity to be dealt with must be considered, especially in reference to storm water. While it might be quite reasonable to construct sewers to take six times, say 30 gallons per head, the problem becomes enormous if 100 gallons per head is to be taken as what may be called unit flow. On the other hand, if the dry-weather flow is, say, 10 gallons per head strength, storm overflows set at six times the dry-weather flow would discharge at only twice the dilution of ordinary 30 gallons sewage.

The question of actual quantity, apart from strength, also has to be considered in the design of disposal works. Tanks, channels and distributing mains, have all to be larger if six times an originally dilute sewage has to be dealt with than if the original sewage is strong. There is also the physical limit of speed within which filters can be operated without water-logging. This question of what is to be taken as the dry-weather flow is, therefore of great importance in calculating the sizes and sort of works necessary to deal with a given sewage.

It is because so few towns give returns of what has actually been thoroughly dealt with at their works as compared with the total quantity received, and the cost of such treatment, that it is so difficult to make just comparisons between one method of treatment and another, or one town and another. It is comparatively easy to get constantly good results when filters are carefully nursed, the test comes when they are called upon to take the day-to-day fluctuations year in, year out.

It is to be hoped that reports giving full data of costs in reference to flow and population will be more frequently published in future by municipal authorities than is now the case. Their value cannot be overestimated.

Cost of Effective Treatment.—From such figures as are available, it may be roughly assumed that the total revenue and capital cost for the production of a good effluent will amount to at least 2s. 6d. per head per annum. For small towns it may be more.

The term "satisfactory effluent" has been used in this paper so far without precise definition. This definition has been given by the Royal Commission in their eighth report as follows:—

"An effluent in order to comply with the general standard must not contain as discharged more than 3 parts per 100,000 of suspended matter, and with its suspended matters included must not take up at 65 deg. Fahr. (18.3 deg. Cent.) more than 2.0 parts per 100,000 of discharged oxygen in five days."

Under certain circumstances they indicate that an even more stringent standard may be called for. Few will deny that if every inland town produced an effluent of the character defined above year in, year out, the condition of rivers, especially in the North of England, would be very different. It can be done at a price, and is done, the author believes by certain towns in the potteries and in the Midlands. The more reason that full statistics should be published for the encouragement of others.

Effect of Dilution.—Where the effluent is considerably diluted by the body of water into which it flows, the commission conclude that the standard may, under proper supervision, be relaxed or suspended altogether.

It is however, by no means easy accurately to judge of the effect of dilution. The problem is in the first place one of efficient mixing. Cases will readily be called to mind where sea-outfalls can become a source of serious nuisance if not carefully chosen. Bombay is an example where, owing to a clerical error, the tidal currents were wrongly marked on a map, the outfall site chosen in consequence has proved far from satisfactory, as the sewage lies in a still pool under Malabar Hill, one of the best residential quarters of Bombay.

Other Problems.—It has been shown that it is possible to dispose of sewage without causing offensive pollution in the body of water into which it is discharged. The outstanding problem remaining is the utilization of the sewage. This has been the dream of the sewage enthusiast ever since modern ways of living forced most people away from the simplicities and economies of the Chinaman. The city of Shanghai makes a handsome profit from the sale of night soil, and the water carriage system is unlikely to be installed there, at any rate in the immediate future, if ever.

With its greater convenience and cleanliness the water carriage system entails constant wastage of valuable fertilizing agents which should come back into the cycle of Nature. That they eventually do so to some extent as fish may be granted, but the world needs wheat, and the fact that the Manchester sewage works and others have been able to sell dried sewage manure at a profit in Canada, that Bradford has concluded a contract for its dried sludge with the intensive gardeners of Northern France, indicates that there is an almost unlimited outlook for properly prepared sewage manure, either alone or as a basis for enrichment by artificial fertilizers. This is the conclusion of Dr. H. Maclean Wilson in a recent report, and the author is quite in agreement with him.

In their conclusions as to the value of sewage sludge the Royal Commission do not appear very convincing. They seem to have insufficiently differentiated between sludges of different origin and composition, and it will be of interest to consider the possibilities of each of these in turn:—

Taking first sludge from sedimentation and chemical precipitation processes, which are very similar in character. The most successful utilization of sludge is carried on at Bradford, Yorks, where the whole sewage, containing as it does, a high percentage of grease from woolwashing, is treated and "cracked" with sulphuric acid, the resulting sludge hot pressed, the grease thus recovered sold at a profit, and the residual cake sent away, as has been said, to France.

At Oldham, Dr. Grossman finds a ready sale for the residue left after distilling away the grease from the sludge. It is largely the presence of soap and fat in sludge which precludes its use as manure, as if they are present it will not readily incorporate with the soil. Ordinary pressed sludge cake also contains seeds of weeds and undesirable plants. Thus, if the grease and these seeds are eliminated, a much more satisfactory product is obtained.

Other kinds of sludge than those referred to above are produced in modern sewage works either by anaërobic or aërobic processes.

The latest development of the anaërobic process is the Emscher tank, the first one of which in this country is now being erected at the Withington works of the Manchester Corporation. The Emscher tank consists of two parts, a settling chamber and a sludge digesting

chamber. The sewage passes through the settling chamber, and the sedimentary matters (other than heavy grit, which must first be removed) fall through a slot in the sludge-digesting chamber, which is much larger than the settling chamber. Here the sludge remains and undergoes thorough fermentation, after which it can be run out, and, owing to the peculiar granular nature which it acquires by fermentation, can be readily dried in properly constructed draining beds. The residue thus obtained is quite inoffensive, and is useful itself as a light manure, and can easily be enriched.

In Dublin a process of fermentation of sludge by addition of yeast is in operation. A considerable separation of water occurs in the process, and the fermented and concentrated sludge is dried in an ingenious manner, and the resultant powder sold by itself for 50s. per ton and more, in proportion to added artificial fertilizers.

The mode of action of the yeast is not properly understood, but it has been suggested as the result of experiment that the yeast breaks down and the cellulose cuticle of the yeast ferments somewhat, yielding hydrogen and other gases which cause the solid matters to rise to the top of the fermentation tank, with separation of a considerable percentage of water.

Fermentation of sludge may also be aërobic, and this takes place in the Dibdin slate filter and the ordinary contact bed or percolating filter. The residuum in a Dibden slate bed has to be washed out from time to time, the filtering medium in a contact bed is taken out from time to time, and the humus from a percolating filter is generally caught in so-called humus tanks. These various products, though probably different in many ways, especially biologically, are at any rate generally free from grease, and are granular and inoffensive in character. They are therefore more readily dried than ordinary tank sludge, and in Manchester it is the "slurry," so-called from the washing of the contact beds, which is being dried, powdered and sold at a price which covers cost.

It will be seen that the function of the filter-bed, whether slate bed, contact bed, or percolating filter, is largely the collection and granulation of the colloidal matters in the sewage or tank effluent.

In an address given in November, 1911, as chairman of the Manchester section of the Society of Chemical Industry, the author made the following among other concluding observations:—

"I cannot forbear to mention also a most illuminating suggestion made to me by Dr. Maclean Wilson, that it might be possible to discover some kind of clotting enzyme, which should do the work which now apparently takes place in the surfaces of the medium of the filter-bed. If this could be done, there is a possibility of enormous saving in costly works." While considering the problem of New York, this question was anew forced on the author's attention. The idea, as an alternative to the scheme of sea-disposal already mentioned, of treating some 1,000,000,000 gallons of sewage daily on percolating filters appeared altogether impracticable in view of the possible nuisance from flies and odors. Chemical treatment of such volumes had also its special difficulties.

But experiments on various systems of forced aëration, and collection of the oxidized solids on surfaces seemed to offer possibilities, according to the experiments of Major Black and Prof. Phelps. At the Lawrence Experimental Station the author saw sewage in a bottle which under certain conditions had been completely purified by nineteen hours' aëration. This work is referred to in the recent annual report of the Massachusetts Board of Health. But the element of surface and consequent cost remained.

Since then it has been possible in the author's laboratory at the Manchester University to go further. The author's assistant, Mr. E. M. Mumford, discovered a bacillus in the water of the old colliery workings at Worsley which has the property of precipitating iron from solution in presence of organic matter. It was then found, as already reported at the congress of the Royal Sanitary Institute at Exeter, that if this organism is added to sewage effluent, together with a little iron salt, and air is blown through, complete clarification results, and the resulting deposit has a very high nitrogen content. Since then the engineering developments of the process have been the chief concern, but it has been possible successfully to inoculate about 5,000 gallons of sewage with a pure culture of the organism, and a plant is now being experimented with capable of dealing with 10,000 gallons per day.

Laboratory experiments are in progress at Davyhulme which indicate even more far-reaching possibilities, and the author looks forward with confidence to the time when it will be possible completely to purify sewage in a tank with production on the one hand of inoffensive sludge, which can be readily handled and disposed of as manure, and of the other on a well aërated effluent, in which aquatic plants and fish will make final use of the nitrogen and phosphates in solution. The problem in its present stage is largely one of engineering, but granted the possibility of applying large quantities of air economically to sewage, the saving in space and capital cost may be very great.

It should be practicable even for seaport towns to purify their sewage without great difficulty before discharge, retaining the insoluble matters in an inoffensive form, easily disposed of as fertilizer. A sewage works will then no longer be a source of nuisance and trouble, either from decomposing offensive sludge, or from flies and odors from percolating filters.

Need for Research.—In conclusion, it is necessary to emphasize again that real advance in the art and practice of sewage disposal must come through the avenue of scientific research of the highest order. It is well to remember that the modern developments are only the practical application of principles discovered long since by men like Pasteur, Warington, Frankland, and many others, without whose work sewage disposal would be mere empiricism.

Such research work necessitates well-equipped laboratories and large staffs of highly trained workers. The author realizes the responsibility in having at his disposal the resources of the Manchester University and the Manchester Corporation for this purpose, but the work is a national one, and it is to be hoped that the present Royal Commission will not be concluded before its work has been put on a permanent footing in the establishment of a national research department which could carry out work of a wider scope than is possible for any one local authority, and could correlate the work done by such authorities to the general benefit of all.

In what has been said the author is not for a moment forgetting that for the practical application of the discoveries of the bio-chemist the close co-operation of the engineer is necessary. It is through this harmonious working together of two great professions that advances may be looked for in the future adequate to the demands of complex modern life.

THE EUGENIA FALLS POWER INVESTIGATION.

In the annual report for the year ending October 31st, 1913, of the Hydro-Electric Power Commission of Ontario, the progress which the engineers of the Commission have made on a scheme for the supply of electric power to Owen Sound, Ont., and surrounding district has been described.

In the 1911 report of the Commission it was stated that the best local source of hydro-electric energy for this district was Eugenia Falls on the Beaver River, and owned by the Georgian Bay Power Company, and a report was prepared based on such data as was then available, demonstrating the value of this source of power. This report indicated that the site had a commercial capacity of about 2,000 h.p. under natural conditions, and about 4,000 h.p. if the total run-off of the watershed could be artificially controlled.

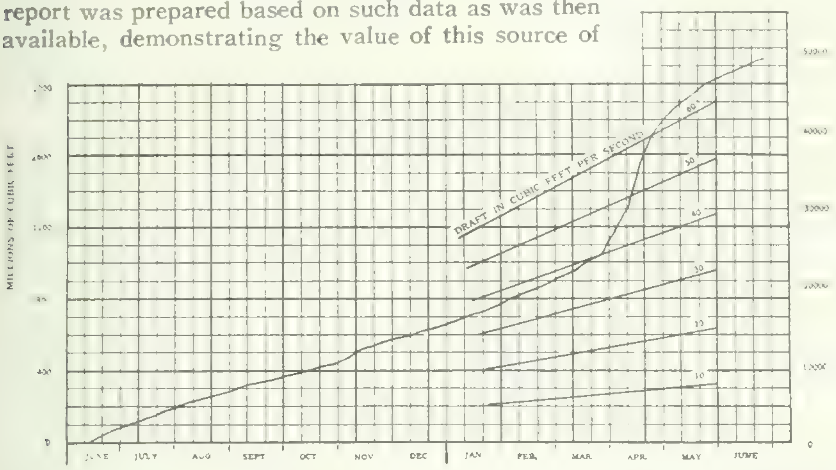


Fig. 1.—Mass Curve, Beaver River, June, 1910, to June, 1911, Inclusive.

Data on River Flow.—With respect to the hydrology of the Beaver River, the present report contains some very interesting data, derived from weir records of the river flow at Eugenia.

To compute the amount of yield of the watershed from the series of daily gaugings for the year ending June 30th, 1911, and to determine the volume of reservoir storage required to store the flood waters in order that any constant rate of flow may be maintained, the mass curve method has been used. Fig. 1 shows the curve obtained.

This method consists of totalling the daily discharges of the watershed from day to day for the whole period, which quantities are then plotted as an irregular line, or "mass curve." Any desired rate of draft may then be assumed, and the amounts necessary at different times plotted to the same scale. If a uniform rate, this draft curve forms a straight inclined line, and if it is made to start coincident with some point or summit on the "mass curve," the ordinate between the two curves at any point serves to show the volume of storage that would be required at this date to have maintained the required rate of draft up to that time. (For further explanation of the mass curve in determining stream flow yield the reader is referred to *The Canadian Engineer* for June 6th, 1913, page 819.)

The mass curve, plotted as above outlined, for the period of June, 1910-June, 1911, gives the reservoir capacities necessary to insure certain uniform rates of flow, beginning with 23 cu. ft. per sec., the minimum flow for the year. These rates of draft, with the required reservoir capacities obtained from the mass curve, are shown in the diagram of required capacity of reservoir for varying rates of draft, Fig. 2. This diagram shows that to secure a uniform flow equal to the mean annual flow (or 65 cu. ft. per sec.), it will be necessary to provide a reservoir capacity of 600 million cu. ft., or about 14,000 ac.-ft. To secure 50 cu. ft. per sec., 245 million cu. ft. of storage or about 5,700 ac.-ft. will be required.

The scheme of development at Eugenia, most economically feasible, is one involving the building of a dam above Eugenia Falls, a diversion canal from the reservoir thus formed, and about 5,000 feet of pipe line for an effective head of 500 feet. The initial development of 2,000 h.p. can be obtained with a dam 23 feet high. When the load builds up sufficiently to warrant extension of the plant, the water to operate an additional unit of 1,000 h.p. can be secured by raising this dam 10 feet. For the final development or full capacity, additional storage can be secured by a dam at Feversham, about 8 miles above Eugenia.

A study of the curves of storage capacities for different contour elevations that have been plotted for dams at Eugenia Falls and at Feversham, when analyzed in connection with the reservoir-draft curves, gives the necessary height to which the dams must be carried for any required amount of flow. The results are shown in the report, together with curves of storage capacities for different contour elevations for Eugenia which are more or less approximate, and which may be changed when further data are obtained from the surveys now in progress.

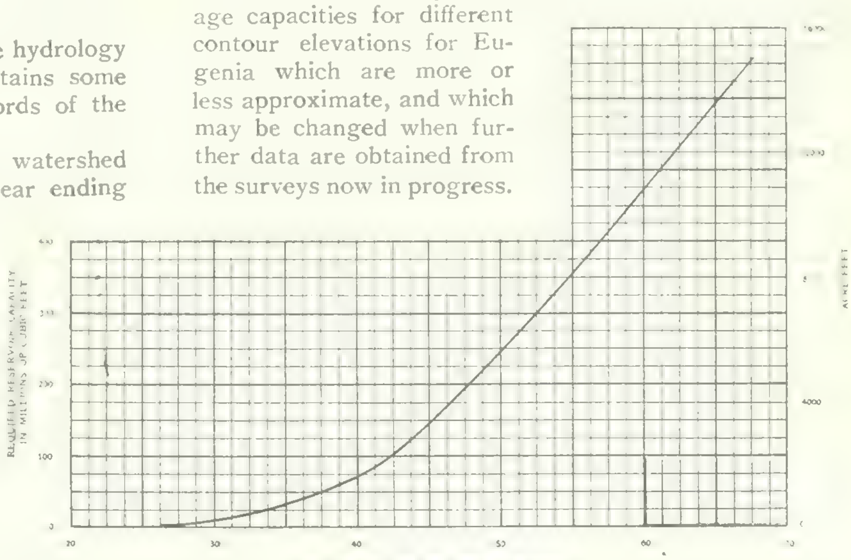

Fig. 2.—Required Reservoir Capacity for Various Rates of Draft, Based on Weir Records, Beaver River, 1910-11.

A reference to the mass-curve (Fig. 1) indicates that the fall replenishment of storage is very limited for this watershed. This conclusion is borne out by the discharges taken during 1913. Thus the storage reservoirs must impound sufficient water during the months of March, April and May to carry over the rest of the year, since it is impossible to depend on a fall filling.

The problem of determining the proper turbine capacity to install at any power-site is a difficult matter,

depending to a great extent on the judgment of the designer. One method of obtaining the economical capacity of a river, to generate power, is by means of a "duration curve." The duration curve is plotted by ranging the several daily discharges in order of their size; i.e., the maximum quantity for any one day in the year is placed as an ordinate over, say, the first day in the year, and so on down to the smallest daily quantity for that year, placed as an ordinate for the three hundred and sixty-fifth or last day of the year. This gives a smooth regular line, as may be seen in Fig. 3, the duration curve plotted for June, 1910, to June, 1911. From this curve the duration during the year of any given river flow may be directly read off.

Experience on rivers used for water power has shown that, in general, the quantity found to obtain at ordinate 182½ on the curve represents the proper and most efficient turbine capacity that may be installed. A variation of 30 days either side of this ordinate is in cases admissible.

The duration curve for 1910 and 1911 represents the flow of a minimum year, as was noted in the 1911 report of the Commission. On the ordinate 182½ the flow is 43 cu. ft. per sec., at 152½ the flow is 48 cu. ft. per sec. It is reasonable to expect that the average flow ordinate at 182½ will be at least 50 cu. ft. per sec., and at 152½ will be 55 cu. ft. per sec. for an ordinary year.

The development will therefore be planned to use the most economic turbine capacity represented by this flow. The ultimate capacity will, of course, be controlled by the later discharge records which will be obtained during the operation of the plant, and which will give more data for fixing the average flow to be expected. The operating records of the plant will also give the load factor to be expected on the complete ultimate development.

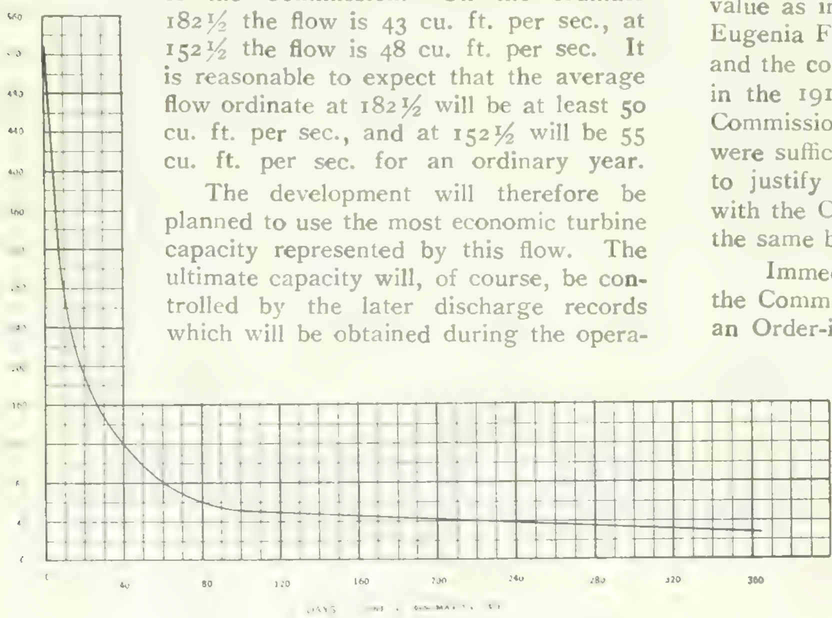

Fig. 3.—Duration Curve, Beaver River.

An inspection of the monthly flow tables for the Beaver River during 1910-11-13, shows a very remarkable coincidence of values for the months of low flow. This is due primarily to the fact that the Beaver River is a spring-fed stream in the fullest sense of the term, ground storage capacity existing to an unusual degree. This condition is in turn influenced by the existence of large tracts of undrained and uncleared swamp throughout the watershed.

Feasibility of the Project.—The success of any scheme of development at Eugenia Falls was dependent, to a large extent, upon the amount of power which could be used in Owen Sound, and upon the willingness of the municipality to enter into a contract for the supply of same. The town took no definite action in connection with the matter until early in 1913, when the light and power commissioners of Owen Sound opened negotiations with the Commission, with a view to ascertaining under what conditions they could obtain a supply of power, having special reference to the possibility of obtaining it from Eugenia Falls. After considerable discussion it was finally agreed that the town of Owen Sound would enter into a contract with the Commission, if it could be proved to the satisfaction of the municipality that Eugenia Falls was capable of supplying the necessary quantity of power. In this connection, the light and power commissioners asked for further confirmation of the data submitted in the report of 1911. While the Commission was satisfied to base its findings upon the 1911 report, it was nevertheless decided to accede to the request of the municipality, and to this end a sharp-crested weir was built at Eugenia Falls, and a recorder employed for the purpose of making continuous measurements of flow, as mentioned above. The light and power commissioners wished particularly to be assured that the records of low water flow, as set forth in the report of 1911, be confirmed, and it so happened that the summer of 1913 was one of the driest on record in that district, so that the results of the 1913 measurements are of great value as indicating the low water power capacity of the Eugenia Falls site. The details of the 1913 investigation and the comparison of the same with the results set forth in the 1911 report indicate that the contentions of the Commission's engineers were sustained, and the results were sufficiently satisfactory to the town of Owen Sound to justify the municipality in entering into a contract with the Commission for the initial supply of 1,200 h.p., the same being executed under date of October 27, 1913.

Immediately following the execution of the contract, the Commission made application to the Government for an Order-in-Council authorizing the Commission to purchase the works, assets, real property and rights of the Georgian Bay Power Company, together with such additional rights as might be necessary, and to develop power at Eugenia Falls and distribute same to the various municipalities in the Owen Sound district. The required Order-in-Council having been issued, the work of making a final survey of the site was commenced immediately and preparations made to proceed with the design of the plant. This work is in progress.

In connection with this development, it may be mentioned that the projected scheme calls for an operating head of 500 feet. With the exception of one or two plants in British Columbia, this will be the highest head in existence in Canada.

The American Institute of Electrical Engineers has authorized the formation of a Panama section There are some 30 members of the Institute now on the Isthmus.

The first railway in Iceland will be under construction in the near future. Plans have been completed, and it is not doubted that these will be accepted by the Althing, or the national assembly of Iceland. The new Icelandic railway will be a narrow gauge line running from Reykjavik through the Thingvalla district - the most fertile part of the island—to Rangavalle, a distance of about 64 miles, with a branch line to the port of Eyrarbakki, an additional 12 miles. Although the track will run through hilly country, the boring of tunnels will be avoided; but a great many bridges are necessary to carry the line across numerous streams. These bridges have to be of especially solid construction, owing to the floods which come down in raging torrents from the mountain sides in the brief Icelandic summer.

AMERICAN ROAD BUILDERS' ASSOCIATION.

At a meeting of the Board of Directors of this association, in New York City, February 24, it was decided to hold the eleventh annual convention and exhibition at Chicago in December, 1914.

The detail for arranging the meeting and exhibition will be in the hands of the Executive Committee, which was re-elected at the last meeting and consists of George W. Tillson, E. L. Powers and R. A. Meeker.

James H. MacDonald, former State Highway Commissioner of Connecticut, was elected a director to fill out the unexpired term of Chief Engineer A. W. Dean, of the Massachusetts Highway Commission, who was elected second vice-president at the annual election of officers last month.

CANADIAN PAVING IN 1913.

THE figures in the accompanying table convey an idea of the activities of Canadian cities during the past year in the matter of street pavements. Last year *The Canadian Engineer* published a general summary on the extent and wear of Canadian pavements, classifying the data collected from civic officials and outlining their opinions, as derived from their observations and experience, of the various types that had been laid under varying traffic, climatic conditions, construction, etc. The reader is referred to our issue of September 25th, 1913, for this information, including the mileages of pavements that were laid prior to 1913.

Of course, the financial stringency which enveloped municipal activities in 1913 is reflected somewhat in the extent to which paving work was carried on. Among the cities reporting upon the season's work, Cranbrook, B.C.; Lethbridge, Alta.; Medicine Hat, Alta.; Moncton, N.B.; Portage la Prairie, Man.; Prince Albert, Sask.; Prince Rupert, B.C.; Revelstoke, B.C.; Rossland, B.C.; St. Hyacinthe, P.Q.; Sydney, N.S., and Trail, B.C., report no permanent paving at all, and are, therefore, withdrawn from their respective places in the table. The statement that they did no paving should be modified slightly, however. In Moncton, N.B., the streets were subjected to considerable opening during the season owing to the laying of natural gas and water mains. All that has been done in Prince Rupert, B.C., in the matter of street work has been a rough grading with a covering of about 3 inches of broken stone, unrolled. All its sidewalks and outlying streets are paved with wood plank. Prince Albert, Sask., and Revelstoke, B.C., have no pavements of any kind. The only work done in Sydney, N.S., was in the nature of repairs. Trail, B.C., carried on operations to the extent of laying about 1,050 square yards of wood plank.

Among the cities included in the table it will be noticed that a few have shown a very small increase for the year. For instance, the extent of paving in Moose Jaw for 1913 consisted of 5,000 square yards of vitrified brick in a subway under railway tracks. It might be mentioned that a very satisfactory pavement was obtained by careful grading, a 5-inch concrete foundation, sand cushion, and the use of 1:1 cement grout. Its cost was $3.53 per square yard.

Reflecting upon the monetary situation, the small showing of some cities in the matter of improvements was naturally to be expected. It should be stated, however, that the extent of paving done is no criterion of the status of the municipality in the eye of the investing public. It is not the desire of *The Canadian Engineer* to show up any lack of activities in paving or to reflect in any way to the difficulties which some cities experienced in selling municipal bonds. Other lines of municipal work were, in some cities, much more needed than paving and asserted their plea for immediate consideration. Again, the indefiniteness of the duration of lull in financial activities prompted economy in the matter of civic expenditure. These and other factors, all of whch have been dwelt upon from every conceivable viewpoint during the past year, brought about a condition in pavement work throughout the Dominion in 1913 that is well illustrated in the returns published herewith.

There are many interesting points to be noted in 1913 paving returns, some of them indicating a decided trend towards uniformity throughout the country, in the matter of general construction, bonding of contract work, withholding of percentage of contract, etc.

Macadam and gravel roads have been included in the list as they form the wearing surface on over half of the paved streets of the cities of Canada and United States, predominating on pleasure drives, in parks and purely residential districts. Eliminating gravel and water-bound macadam from the total, it is found that 93% of the three million square yards has been laid on a concrete foundation of thickness varying from 4 to 6 inches. The adoption to this extent of concrete for foundation work shows its general acceptance in the majority of our cities.

Winnipeg is the only city to report the laying of untreated wood block during the year. Using two 1-inch boards under it, 2,285.35 square yards were laid by city day labor.

More uniformity shows itself in the term of years through which a pavement is bonded, than had been noted in previous years. St. John, N.B., requires a 20-year bond. Guelph, London, Ottawa, Toronto and Windsor stipulate 10 years. Of the remainder, twenty cities require only 5 years. In the case of London, on a 10-year guarantee a bond is taken over 5 years from a guarantee company for 50% of the amount of the contract together with the contractor's bond over 10 years with a 6% retention. Montreal bonded its stone and wood block for one year only. Quebec bonded its stone and Scoria block for two years. St. Catharines made it three years in the case of Rocmac, used on hilly approaches to the city and on residential streets with grades. Toronto bonded its Rocmac and Dolorway for three years. Vancouver bonded its creosoted wood block for one year by the contractors and required a 10-year guarantee from the manufacturers of the blocks. Winnipeg had some 4,800 sq. yds. of concrete pavement laid by contract without bond, and Woodstock laid a small amount under the same conditions.

In their contract work Edmonton, Guelph, Montreal, New Westminster, Ottawa, Quebec, Regina and St. Boniface withheld 10% of the amount of contract. St. John, Saskatoon, Stratford, and Windsor kept back 5%. Toronto withheld 15%; St. Catharines withheld 33% on asphaltic concrete and 35% on Rocmac work. Westmount had 20% of the amount of its sheet asphalt contracts covered by bond by the contractor, put up for 5 years. In Westmount during the progress of the asphalt work, progress certificates are issued monthly to the amount of 80% of the work completed, a final payment of the whole amount of the contract being made immediately after the completion of the work.

Extent of Paving in Canadian Cities during 1913

City*	Asphalt Block	Bitulithic	Brick	Concrete (Plain or Tarred)	Gravel	Macadam (Asphalt or Tar)	Sheet Asphalt	Stone Block	Wood Block (Untreated)	Wood Block (Treated)	Water Bound Macadam	Asphaltic Concrete	Total in Sq. Yds.

CONTENTS OF THIS ISSUE.

A MOVEMENT AMONG ENGINEERS FOR BETTER PUBLIC SERVICE.

Engineers who have at heart an altruistic desire for the betterment of public service will find it very encouraging to review the work during 1913 of the American Institute of Consulting Engineers. With a membership of 70, the majority of whom reside in New York State, and six of whom, it may be added, reside in Canada, the Institute is doing the country, and the profession as well, a great deal of good.

Perhaps no better examples of the justification of its existence can be presented than those outlined in a brief review of its 1913 activities. From time to time committees were appointed from its membership to urge the appointment of engineers as members of commissions and as heads of departments of public service having to do with engineering matters. The opening arguments of these committees are, in themselves, quite characteristic of the motives of the Institute.

In January, 1913, a presentation was made to the Governor of New York State for the appointment of engineers on public service commissions, which began: "We have no personal or individual ambitions to serve and no candidates to present, but as citizens, however, and expressing the sentiment of a body of professional men who, more than any other understand the problems involved in the execution and management of great public works, we may be permitted an altruistic viewpoint and speak for what we believe to be the best interests of the city and State."

In April, a communication to the Interstate Commerce Commission, recommending the creation of an advisory board of engineers in connection with the valuation of railroads, maintained the same viewpoint, as follows:

"It is perhaps not understood by the general public that the results of this great work will be of vital import to all classes of citizens, investors and non-investors alike, and that the general well being of a vast community is indissolubly bound up with the outcome."

Similar purposes were expressed on another occasion in advocating the organization of an engineering commission to act with the consulting architect of New York. And, later, in urging the appointment of engineers on public service commissions of the state, expression of the views of the Institute of the standard to which these appointments should conform was given as follows:

"In thus urging the appointment of engineers on the public service commissions, we recognize that their selection should not be based on their technical attainments alone, but also on the same degree of business and administrative acumen that should be possessed by appointees from other walks of life." Again, "That high character, tact and business and administrative ability are absolutely necessary qualifications for anyone competent to fill these positions, and we believe that these departments cannot be administered with the efficiency and economy that you desire unless they are under the leadership of such types of engineers."

In a communication to the President of the United States, advocating the appointment of an engineer on the Interstate Commerce Commission, it was observed: "The Institute has no candidate to present for office and is therefore enabled to address you from an impartial stand-

point, free from personal ambitions and solely in behalf of the public interests."

This brief summary of the aims and activities of the organization, recalls our need in Canada for the performance of a similar duty to the public. It may often be disagreeable, and sometimes misinterpreted, as there is at times the semblance of a pronounced unbelief that any act of man can be unselfish. But, every province and every city has instances of its own as evidence of the fact that sound engineering knowledge and ability is not always called into service when it should be. The public at large is unaware of the existence of this strength. It is common knowledge only among those in direct touch with efficient engineering service. It is the duty of engineers themselves to advocate its inception into public affairs, in the face of injustifiable criticism of selfish motives, and the blowing of trumpets. The American Institute of Consulting Engineers has attacked the problem in a manner that is safe and sane and certain to bear creditable fruit.

EDITORIAL COMMENT.

Previous to its deliverance on April 7th, the budget speech of the Minister of Finance at Ottawa maintained live interest in the Canadian iron and steel market—interest that remained curiosity with some had engendered anxiety on the part of others, the latter being chiefly those associated with the iron and steel industry from a manufacturer's point of view. It was not generally expected that the Government would extend further assistance, except a possible revision in the nature of protection to wire rods, for which several important corporations had so long and vigorously contended.

As noted in next column, wire rods received a duty of $3.50 per ton under the general tariff and $2.25 under the British preferential. As but a small proportion is brought in from England, the industry will practically get the advantage of the $3.50 tariff.

The Dominion Iron and Steel Corporation and the Steel Company of Canada are the chief companies affected by this change. Managers of both companies have expressed themselves pleased with the new duty.

As for the structural steel industry, also affected by new duties, it is not easy to acquire a general opinion at such an early date. Some structural men have discussed the tariff and the effect it will probably have on the cost of building, which, they claim, is already too high.

* * * *

Mr. Geo. A. Janin, City Engineer of Montreal, recommends the appointment of a board of technically trained engineers to assist in the execution of duties pertaining to the various departments under his direction. It is stated that he also advises that a deputy chief engineer be appointed.

The department of roads, bridges and tunnels is temporarily in the charge of Mr. J. H. Dubuc, by appointment of the late Board of Control. Mr. G. R. Macleod is in charge of railways, while for the third department, that of sewers, waterworks and municipal buildings, no member of the board has yet been appointed. One of the first duties of the new board of control will be to consider the appointment of this complete staff.

CHANGES IN THE TARIFF SCHEDULE.

THE changes effected by the new tariff schedule submitted by the Minister of Finance in his budget speech to the House of Commons on April 6th, comprise a number of items of interest to readers of *The Canadian Engineer.*

The following items have a direct bearing upon engineering construction, particularly in the case of the iron and steel industry:

Rolled iron or steel angles, beams, channels and other rolled shapes and sections of iron or steel not punched or drilled or otherwise further manufactured, weighing over 120 pds. per lineal yd., not otherwise provided, not square, flat, oval or round shapes, and not being railway bars or rails, changed from $2, $2.75 and $3 to $2, $3 and $3 per ton under British preference, intermediate and general tariffs, respectively.

Galvanized hoopsteel changed from 30% to $7 per ton, general tariff.

Wrought or seamless iron or steel tubing, from 4 to 10 in. diam., changed from 10, 12½ and 15% to 20, 30 and 30%.

Wrought or seamless iron or steel tubing over 10 in. in diam., changed from 10, 12½ and 15% to 10, 15 and 15%.

Coil chain and links 1¼ in. in diam. and over, changed from 5, 7½ and 10% to free, 5 and 5%.

Coil chain and links under 1⅛ in., changed from 5, 7½ and 10% to 15, 20 and 20%.

Malleable sprocket chain or link belting chain made free when used in agricultural implements, whereas it was formerly free for all purposes.

Rolled round wire rods in the coil of iron or steel, not over ⅜ in. in diam., changed from free to $2.25, $3.50 and $3.50 per ton, when imported to manufacture wire in the coil; for use in the manufacture of chain changed from free to $2.25, $3.50 and $3.50.

Chloride of lime and hypochlorite of lime, in packages of not less than 25 pds., transferred from the free list and made dutiable at 10c. and 15c. per cwt. When in packages of less than 25 pds., 17½, 25 and 25%, instead of free.

Cork slabs, boards, planks and tiles produced from cork waste or ground cork, changed from 15, 17½ and 20%, to 20, 30 and 30%.

Building stone, sawn on four sides, is made dutiable at 15c. per cwt., and when further manufactured at 45c., instead of 20%, as formerly.

Carbon electrodes of over 35 in. in circumference, changed from 3 to 20%.

Ferrosilicon made $4.50 a ton, instead of $2.50.

Ferro-manganese and spiegeleisen changed from $2.50 a ton to free.

Among the provisions for drawbacks are the following:—

Lapwelded tubing of iron or steel, not less than 4 in. in diam. and used in casing wells or for natural gas transmission, 50%.

Bituminous coal, drawback of 99% of duty extended to coke ovens, other than those owned by smelting works, when intended for smelting and melting ores.

Wire rods used for the manufacture of fencing wire, 9, 12 and 13 gauge, 99% of duty.

Charcoal used for smelting of ores, 99%.

Rolled hexagon iron or steel bars used in the manufacture of cold-drawn or cold-rolled iron or steel bars or turned and polished shafting, 99%.

THE STEEL HARDENING PROCESS.

By R. H. Cunningham, B.A.Sc.,
General Manager, Canadian Hoskins, Limited,
Walkerville, Ont.

ORIGINALLY the name "steel" was applied to various combinations of iron and carbon, there being also present, as impurities, small proportions of silicon and manganese. At the present time, however, the use of the name is extended to cover combinations of iron with tungsten, vanadium, nickel, chromium, molybdenum, titanium and some of the rarer elements. These latter combinations are quite generally known as the "alloy steels" to distinguish them from the "carbon steels," those in which the characteristic properties are dependent upon the presence in the steel of carbon alone. The alloy steels are divided into the "high speed" steels and the Mushet or "air-hardening" steels.

The specific properties that distinguish these different steels are due in part to their respective compositions, i.e., to the particular elements they may contain and the relative proportions in which these occur, and, in part, to their subsequent working and heat treatment.

Effect of Difference in Composition.—In general, any change in the composition of a steel results in some change in its properties. For example, the addition of a certain metallic element to a carbon steel causes, in the alloy steel thus formed, a change in position of the proper hardening temperature point. Tungsten or manganese added, tend to lower this point; boron and vanadium, to raise it. The amount of the change is practically proportional to the amount of the element added.

Further, adding a small proportion of carbon to iron produces steel, which has decidedly different properties than pure iron. Increasing the proportion of carbon in the steel thus formed, within certain limits, causes a variation in the degree in which these properties manifest themselves. For example, consider the property of tensile strength. In a 0.1 carbon steel (one in which there is present but 0.1% of carbon) the tensile strength is very nearly 25% greater than that of pure iron. Adding further carbon causes this to rise, at approximately the rate of a 2.5% increase in tensile strength for each 0.01% of carbon added.

Due alone to differences in proportion of carbon present, carbon steels are divided into three classes. The first of these embraces the "unsaturated" steels, those in which the carbon content is lower than 0.89%; the second, the "saturated" steels, in which the proportion of carbon is exactly 0.89%; and the third, the "supersaturated" steels, those in which the carbon content is higher than 0.89%.

Effect of Heat Treatment.—With a steel of a given composition, proper heat treatments may be applied which of themselves will alter in form or degree some of its specific properties, or practically eliminate one or more of them, or, perhaps, add certain new ones. Physical properties of size, shape and ductility are examples of the first. Of the second, heating a steel beyond its hardening temperature takes away its magnetism, making it "non-magnetic." And the third, the property of hardness—for practical purposes—may be added to a steel by the process of hardening. In connection with this it must be understood that strictly speaking, "hardness" is a relative term and that all steel has some hardness.

There are three general heat treatment operations so considered—forging, hardening and tempering. In all of these the object sought is to change in some manner the existing properties of the steel; in other words, to produce in it certain permanent conditions. Each of these operations, broadly speaking, consists of two parts, viz., raising and lowering the temperature of the piece. (In forging, of course, mechanical work is also done upon it.)

Obviously then, the controlling factor in all heat treatment is temperature. Whether the operation is forging, hardening or tempering, there is, for any certain steel and particular use thereof, a definite temperature point, at which to work the steel, that alone gives the best results. Insufficient temperatures, either through ignorance of what the correct point is, or through inability to tell when it exists, cause "burned" steel. This is a common failing, resulting in great loss. In degree, very slight variations, from the proper point, may do irreparable damage.

Due to temperature variation alone, steel may be had in any of three conditions: (1) in the "unhardened" or annealed state—when not heated to temperatures above 735° C. (1355° F.); (2) in the "hardened" state—by heating to temperatures between 735° C. (1355° F.) and 820° C. (1508° F.); (3) in a state softer than (2), though harder than (1), when heated to temperatures which exceed 820° C. (1508° F.).

The Hardening Process.—Hardening a carbon steel is the process of increasing its degree of hardness, this property being its power to resist penetration. It is the result of a change of internal structure which takes place in the steel when heated properly to a correct temperature. In the different carbon steels this change for practical purposes is effective only in those in which the proportion of carbon is between 0.2% and 2.0%.

When heated, ordinary carbon steels begin to soften at about 200° C. (392° F.) and continue to soften throughout a range of 170° C. At the point 370° C. (698° F.) practically all of the hardness has disappeared. "Red hardness" in a steel, is a property which enables it to remain hard at red heat. In a high-speed steel this property is of the first importance, 550° C. (1022° F.) being a minimum temperature at which softening may begin. This is some 350° C. above the point at which softening commences in ordinary carbon steels.

The process of hardening a steel is best carried out in a closed furnace. Of the many sources of energy capable of producing the required heat, electricity offers the most attractive advantages. The electric resistance furnace, as now built in such a variety of sizes of either muffle or tube chamber types, has one fundamental point of superiority over all coal, coke, gas or oil-heated furnaces. *It is entirely free from all products of combustion*, the heat being produced by electrical resistance. This is important. It does away with the chief cause of oxidation of the heated steel. Further, the temperature of the electric furnace can be easily and accurately regulated to, and maintained uniform at, any desired point. When electric power is generated for other purposes, the increased cost of this form of energy for operating furnaces is not sufficient to orgue against it. Even when current is purchased, the superior quality of work performed by this kind of furnace, frequently more than offsets the slightly higher cost of operation.

In the actual heating of a piece of steel, it is essential to good hardening that small projections or cutting edges are not heated more rapidly than is the body of

the piece, i.e., that all parts are heated at the same rate, and also that all parts are heated to the same temperature. These conditions are facilitated by slow heating, especially in case the treated piece is large. A uniform heat, as slow in temperature as will give the required hardness, produces the best product. Lack of uniformity in heating causes irregular grain, internal strains and may even produce surface cracks. Any temperature above the "critical point" of a steel tends to open its grain—to make it coarse and to diminish its strength, though such a temperature may not be sufficient to lessen appreciably its hardness.

Critical Temperatures.—The temperatures at which take place the previously mentioned internal changes of structure of a steel, are frequently spoken of as the "critical points." These are different in steels of different carbon contents. The higher the percentage of carbon present, the lower the temperature required to produce the internal change. In other words, the critical points of a "high" carbon steel are lower than those of a "low" carbon steel. In steel of the commonly used carbon contents there are two of these "critical temperatures," called the "decalescent point" and "recalescent point" respectively.

The decalescent point of any steel marks the correct hardening temperature of that particular steel. It occurs while the temperature of the steel is rising. The piece is ready to be removed from the source of heat directly after it has been heated uniformly to this temperature, for then the structural change, necessary to produce hardness, has been completed. Heating the piece slightly higher may be desirable for either or both of the two following reasons: (1) In case the piece has been heated too quickly, and not uniformly, this excess temperature will assure the structural change being complete throughout the piece; (2) any slight loss of heat which may take place in transferring the piece from the furnace to the quenching bath may thus be allowed for, leaving the piece at the proper temperature when quenched.

If a piece of steel, which has been heated above its decalescent point be allowed to cool slowly, it will pass through a structural change, reverse to that which takes place on a rising temperature. The point at which this takes place is the "recalescent point" and is lower than the rising critical temperature by some 30° to 100° C. (86° to 212° F.). The location of these points is made evident by the fact that while passing through them the temperature of the steel remains stationary for an appreciable length of time. It is well to observe that the lower of these points does not manifest itself unless the higher one has been first fully passed.

It is for the reason that these critical points are different for different steels, that they cannot be definitely known, for any particular steel, without an actual determination.

Heating a piece of steel to its correct hardening temperature thus produces a change in its structure, which makes possible an increase in its hardness, but this condition is only temporary unless the piece is "quenched."

Quenching.—This treatment consists in plunging the heated steel into a bath, cooling it quickly.

By this operation the structural change seems to be trapped and permanently set. Were it possible to make this cooling instantaneous and uniform throughout the piece, it would be perfectly and symmetrically hardened. This condition can not, however, be realized, as the rate of cooling is affected both by the size and shape of the treated piece; the bulkier the piece, the larger the amount of heat that must be transferred to the surface and there dissipated through the cooling bath; the smaller the exposed surface in comparison with the bulk, the longer will be the time required for cooling. Remembering that the cooling should be as quickly accomplished as possible, the bath should be amply large to dissipate the heat rapidly and uniformly. Too small a quenching bath will cause much loss, due to the resulting irregular and slow cooling. To insure uniformly quenched products the temperature of the bath should be kept constant so that successive pieces immersed in it will be acted upon by the same quenching temperature. Running water is a satisfactory means of producing this condition.

The composition of the quenching bath may vary for different purposes; water, oil or brine being used. Greater hardness is obtained from quenching, at the same temperature, in salt brine and less in oil than is obtained by quenching in water. This is due to a difference in heat-dissipating power possessed by these substances. Quenching thin and complicated pieces in salt brine is unsafe as there is danger of the piece cracking, due to the extreme suddenness of cooling thus produced.

In the actual round of shop work the steel to be hardened is generally of a variety of sizes, shapes and even compositions. To obtain uniformity both of heating and of cooling, as well as the correct limiting temperature, the peculiarities of each piece must be given consideration in accordance with the above outlined points. In other words, to harden all pieces in a manner best adapted to but one, would result in inferior quality and possible loss of all except this one. Each different piece must be treated individually in a way calculated to bring out the best results from it.

Theory.—The presence of these critical points in the heating and cooling of a piece of steel is a phenomenon. The most reasonable theory advanced to explain this is as follows:—

While heating, the steel uniformly takes on heat. Up to the decalescent point all of the energy of this heat is exerted in raising the temperature of the piece. At this point, the heat taken on by the steel is expended, not in raising the temperature of the piece but in work, which produces the internal changes here taking place between the carbon and the iron. Hence, while the heat added is being taken up in this manner, the temperature of the piece, having nothing to increase it, remains stationary or, due to surface radiation, may even fall slightly. After the change is complete the added heat is again expended in raising the temperature of the piece, which increases proportionally.

When the piece has been heated above the decalescent point and allowed to cool slowly, the process is reversed. Heat is then radiated from the piece. Until the decalescent point is reached, the temperature falls uniformly. Here the internal relation of the carbon and the iron is transformed to its original condition, the work required to do this being converted into heat. This heat, set free in the steel, supplies for the moment the equivalent of that being radiated from the surface. While this condition holds, the temperature of the piece ceases falling and remains stationary. Should the rate of evolution of heat from the internal changes be greater than that of surface radiation, the resulting temperature of the piece will not only cease falling, but will obviously rise slightly at this point. In either event the condition exists only momentarily, for when the carbon and iron

constituents have resumed their original relation, the evolution of internal heat ceases and the temperature of the piece falls steadily, due to surface radiation.

The Practical Problem.—From the foregoing sections it is evident, first, that there is a definite temperature at which to best harden any carbon steel, and second, that there results great loss, both of labor and material, unless the hardening is carried out at this temperature.

The actual shop problem thus presented is to determine readily and accurately the correct hardening temperature for any carbon steel that may be in use.

[A practical means of solution, even by one who is not an expert, will follow this article at an early date, comprising a description of apparatus and methods.—Editor.]

MUNICIPAL WORK IN SOUTH VANCOUVER.

Mr. S. B. Bennett, who has recently assumed the duties of board of works and waterworks engineer for the district of South Vancouver, sends in the following summary of street improvements carried out in that municipality up to December 31st, 1913.

South Vancouver has an area of over 9,000 acres or 14½ square miles, with a population of about 40,000.

Total mileage of streets in municipality	246.5
Mileage of streets cleared and rough graded	204.0
Mileage of street uncleared	42.5
Mileage of streets macadamized	35.4
Mileage of paved roadways	3.84
Mileage of planked roadways	12.00
Mileage of sidewalks laid	117.83
Mileage of street car lines, double track	4.57
Mileage of street car lines, single track	6.02
Mileage of single track, interurban railway	4.70
Mileage of double track, interurban railway	2.08
Number of wooden bridges built	7
Number of concrete catch basins	76
Number of wooden catch basins	76
Number of concrete manholes	11
Mileage of wooden box drains and culverts	13.14
Mileage of sewers laid	.15
Mileage of storm sewers laid	2.50
Mileage of concrete curb only laid	.24

Waterworks Department.

	1910.	1911.	1912.	1913.	Total.
Miles of water mains laid	76	69	39	15	199
Fire hydrants installed	132	169	216	66	583
Services installed	2,007	2,753	2,373	1,689	8,822

Like most other municipalities, South Vancouver has been suffering from the financial depression but is looking forward to considerable activity this season. Considerable paving work is proposed. The waterworks committee is also building a steel water tank of 750,000 gal. capacity. When completed it will be 75 ft. high and 45 ft. in diameter. The cost of the tank, painted and enamelled, will be $30,000.

To preserve ste[illegible] fr[illegible] rus[illegible] [illegible] 1 part [illegible]outchouc and 16 parts turp[illegible]ntine [illegible], [illegible] 8 parts boiled oil, and mix by bringing [illegible] boiling water. Apply to the steel with a brush, the same as varnish. It can be removed again with a cloth soaked in turpentine.

REPORT ON THE MAITLAND RIVER AS A POWER PROJECT.

A REPORT on the power possibilities of the Maitland River, Ontario, is given in the sixth annual report of the Hydro-Electric Power Commission of Ontario. Since the preparation of the preceding report, continuous daily gauge readings were made at Benmiller, and these readings, with the aid of a rating curve of the stream, compiled from the regular monthly measurement of discharge, furnished the data for a further study of the hydrology of the river in its relation to the development of power.

The report contains duration curves plotted for the years 1911, 1912 and 1913, indicating that the amount of flow for economical development on this river ranges from 300 cu. ft. per second on the 212½ ordinate to 1,000 cu. ft. per second on the 152½ ordinate.

In last year's report the abnormal flow characteristics of the Maitland River were noted, and attention was drawn to the fact that any development of power must depend for continuous operation on the minimum flow of the stream in conjunction with such advantages as can be derived from local pondage.

During the summer of 1913, on a number of days the minimum flow of the stream was 75 cu. ft. per second. At the Black Hole site, with an operating head of 80 ft., this flow, without pondage, gives a minimum continuous power capacity of about 545 h.p. The local pondage above the Black Hole dam would be something over 700 acres. Assuming a maximum draw on this pond of 5 ft. (thus giving a minimum operating head of 75 ft.), a reservoir capacity of 3,500 acre-feet would be available.

An analysis of the mass curve of the Maitland River from 1911 to date, shows that 3,500 acre-feet of reservoir capacity will provide a continuous discharge of about 110 cu. ft. per sec. In extremely dry years it is probable this flow would not exceed 100 cu. ft. per sec.

From this the report ventures to state that any power development on the Maitland River at the Black Hole site could not be depended upon to deliver continuously more than 750 h.p.

The following table gives the amount of storage required for different rates of uniform draft up to 200 cu. ft. per sec., with the continuous available power for these amounts, if developed at the Black Hole:

Required Storage in Million cu. ft.	Storage in Acre feet	Uniform Flow in cu. ft. per sec.	Continuous Power Available
0	0	75	545 h.p.
80	1,835	100	725 h.p.
260	5,960	125	910 h.p.
520	11,920	150	1,090 h.p.
800	18,350	175	1,270 h.p.
1,100	25,230	200	1,450 h.p.

The table shows that for the development of 1,500 h.p. of continuous power at the Black Hole about 25,000 acre-feet of storage will be required. Owing to the fact that facilities for storage in the Maitland River watershed are lacking to an unusual degree, the purchase of land construction of the necessary works would entail an expenditure which, added to abnormal cost of development at the Black Hole, places the project, for the time being, outside of economic limits as a source of continuous power.

The rapid development in the quality of steel must be credited to a great extent to the automobile and the aëroplane. Wire [illegible] to 0.102 inch diameter, with a tensile strength of 350,000 pounds per square inch.

TORONTO WATERWORKS REPORT DISCUSSED.

The Toronto City Council has before it two reports on extensions to the waterworks system of the city. They are that submitted by R. C. Harris, Commissioner of Works, in January last, and an earlier one, presented in 1912 by a board of experts appointed in 1911 by the city. Summaries containing the fundamental points of each were published in *The Canadian Engineer* for January 22nd, 1914, and May 30th, 1912, respectively.

The later report severely criticized the recommendations of the former, and it has been, in turn, subjected to criticism of a somewhat similar nature by the engineers of the former investigating board. On January 24th, Willis Chipman, C.E., its secretary, forwarded a memorandum in which it was demonstrated that at an intake located opposite Victoria Park, the site recommended by the Commissioner of Works, the pollution of the water supply would be eight times that at the intake at Scarboro, proposed by the board of experts, this statement being based on the assumption that an intake crib be located in the same depth of water and at the same distance from shore at each of these two points.

A second memorandum forwarded by Mr. Chipman to the Board of Control recently, deals further with the two proposals. Following are interesting abstracts from it:—

"It should be noted that we recommended that the Scarboro crib be located 2 miles from shore, and at a point where the depth of water is double that at the proposed intake crib at Victoria Park. There can be no reasonable doubt, therefore, that the pollution of the supply through the Harris intake off Victoria Park, would be at least ten times greater than at the proposed intake off Scarboro Heights.

"Our designs for an intake crib have been most unfairly criticized. We did not state in our report that the structure was to be built within the harbor and floated to place, as illustrated in the diagram annexed to the Harris report. Intake cribs of the proposed height have not been sunk for waterworks purposes owing to the fact that the water in the other great lakes in the vicinities of the large cities have not the depth of Lake Ontario at Toronto, but cribs of greater depths have been sunk at other places for bridge piers and abutments, of which full descriptions are available in engineering publications.

"We also, as a board, obtained offers from responsible and experienced contractors to construct an intake crib in this depth of water, whether built of concrete or steel, who were prepared to submit bonds as a guarantee that they would carry out the work to successful completion.

"We have been taken to task by Commissioner Harris for not having made a sufficient number of borings to determine the practicability of a tunnel at the depth proposed. In explanation I may state that it was not until the latter part of November, 1911, that the board finally concluded to recommend the Scarboro project, and as we were being urged by the council and the newspapers to complete our labors, and as it would have taken another full summer season to make the borings, we decided to submit our report, in which we expressed the opinion that shale of a similar character to that beneath Toronto harbor would be found beneath the lake off Scarboro, this opinion being based upon borings made by us at the Scarboro shore upon information received from the geological survey at Ottawa, and statements made by Prof. Coleman, of the University of Toronto, who has made a special study of the Scarboro formations. The borings recently made by Smith and Travers have confirmed our opinion.

"The leakage into the tunnel beneath the harbor during construction was only about 350 gal. per min., a trifling amount. All the evidence points to the fact that the shale off Scarboro is of precisely the same character as under the harbor, practically dry and without seams or faults.

"If, however, borings should demonstrate that we made an error in judgment, there is no reason why the Scarboro intake crib could not be located in the same depth of water and at the same distance from shore as that now advocated by Mr. Harris. The Scarboro intake would then be about 7 miles from the point of pollution instead of 2½ miles.

"Before concluding our report we consulted one of the foremost tunnel experts in America, who visited Toronto at the request of the chairman of the board, examined our designs and pronounced them practicable.

Reservoir Supply.

"We propose to pump water to an elevated reservoir, not for the fun of seeing it run down hill again, but to supply all of the city north of College Street, and the higher sections not now receiving a city supply. The College Street line, which now divides the intermediate service from the lower service, was to be maintained for the present, but we anticipated that this line might be lowered; that is, some street to the southward might be adopted in the future as the northern boundary of the low level district, this lower district to be served exclusively by the present John Street station.

"Assume two municipalities, one, say, 200 ft. higher than the other—there can be no reasons advanced why they cannot be supplied by two independent pumping stations. Connecting the two systems by one or more pipes provided with check valves and gate valves, permits either area to be supplied from the other in case of emergency, as was done recently in the city of Montreal when portions of the city were supplied by the Montreal Water and Power Company.

"When enlarged and improved, the old works may be depended upon for a minimum of 60,000,000 and a maximum of 90,000,000 gal. per day. The John Street system will then meet the demands of a population of something over 500,000, which will probably be reached within the next few years.

"The supply from Scarboro reservoir might, however, be drawn upon in case of a break-down in the John Street system.

"We did not recommend or propose that the entire water supply should be pumped to a height of 370 ft. We did not propose that the new reservoir should be operated in connection with the present city system, nor with the Rose Hill reservoir, excepting in case of emergency, and all of Mr. Harris' assumptions respecting the overflowing of the Rose Hill reservoir and the interference at the John Street pumping station, rendering the old plant useless, are simply nonsense.

"In regard to reservoirs, Commissioner Harris cites several large cities without reservoirs, but he fails to state that in each of these cities there is no ground of sufficient elevation upon which to construct a reservoir. It is hardly necessary to call attention to the fact that we did not recommend the city of Toronto to construct

a mountain or hill upon which to erect a reservoir, but simply took advantage of what nature had provided.

"At Cleveland the capacity of the reservoir is over 100,000,000 gal., and dozens of cities might be mentioned where the reservoirs are of even greater capacity. If the city of Montreal had been provided with a reservoir containing 3 or 4 days' supply, the recent water famine might have been averted. At the rear of Mount Royal, a large reservoir for the Montreal Water and Power Co. is now in course of construction, and the fire underwriters and expert engineers have recommended additional storage reservoirs to lessen the possibility of water famine.

"We admit that there would be a loss of pressure due to friction. The longer the conduit and the smaller its diameter, the greater the friction, but, if I am not mistaken, the citizens of Toronto would prefer paying the trifling extra cost of pumping water through a few miles of large pipes, to the cost of the extra amount of chloride of lime necessary to disinfect a more polluted water supply, and the extra cost of filtration at the Victoria Park station.

"Furthermore, the extra cost of pumping through the mains, which would not exceed 10 or 12 pounds, would be offset by the extra cost of the pumping at Victoria Park. All of the water at this point will require to be pumped twice, first to the filters by low lift pumps and second by high lift pumps into the distribution system. No practical man will deny that pumping water twice will cost more than pumping it once to the combined height of two pumpages. The records at the John Street station and at the filtration plant, will, without a doubt, prove the above statement, but as no report of the city engineer or the public works department has been published since 1911, the public is in the dark respecting costs of operation and maintenance.

"In regard to the length of the proposed steel conduit from Scarboro westward, the distance is only four miles greater than with the Victoria Park scheme. With a new steel conduit of this length under an exceptionally light head, the possibility of breakage or interruption would be a minimum. When the population of the city of Toronto reaches 700,000 people, a second conduit will probably be required, but no one can foresee where this additional population will be distributed, and we did not, therefore, consider it advisable to include a duplicate conduit in our project. In an emergency, if the new conduit should for any reason be closed for repairs or inspection, the high level district could be supplied as it is at present by the high level pumping station, the water to be taken from the low level district and the Rose Hill reservoir.

"In regard to booster stations, the costs were not included in our report as we did not consider they would be required for a few years.

Pumping Machinery.

"In regard to pumping machinery, our recommendation was for an electric plant. The city had at that time contracted for a large block of electric power, electric pumps were being installed at the John Street station, and at the high level station, and as patriotic citizens we advocated electric power, on condition that two independent transmission lines should be constructed, also a reservoir of 130,000,000 gal. capacity.

Mr. Harris' statement respecting the pumpage of the entire water supply to a height of 370 ft. has been pointed out as incorrect. Of the 15,000,000 gal. per day now pumped at the John Street station, about 15,000,000 gal. per day is now re-pumped at the high level station, and the volume re-pumped is increasing rapidly each year. Mr. Harris' report only confirms that made by our commission.

"The maximum daily consumption in the low level district (south of College Street) is now given as about 50,000,000 gal., and in the high level districts, about 22,000,000 gal., or 72,000,000 gal. now pumped at John Street, of which 22,000,000 gal. are re-pumped at Poplar Plains station.

Pollution at Intake.

"Assuming two points near the north shore of Lake Ontario where the water is practically of the same depth and at the same distance from shore, the pollution due to the main sewer outlet near the Woodbine will vary inversely as the squares of the distances from the sewage outfall. This is axiomatic and can not be controverted.

"It must also be admitted that if the distance from shore be doubled and the depth of water also doubled, that the pollution will certainly be less than half. At Victoria Park intake, the supply under existing conditions would unquestionably be polluted at least four fold what it is at present, while at Scarboro the pollution would undoubtedly be less than one-half what it is at present, and probably less than one-fourth.

"The Harris report states that further treatment of the sewage of the city will be necessary if the water supply be taken from Victoria Park, also that the water supply should at all times be chlorinated. thus admitting the certainty of gross pollution."

ASBESTOS PRODUCTION IN QUEBEC.

The Province of Quebec contains the principal asbestos-producing areas of Canada. The present workable deposits are scattered through the great serpentine range which strikes through the townships of Broughton, Thetford, and Coleraine. The total length of the belt is 23 miles, with a width of 100 feet in the extreme easterly part, increasing to 6,000 feet in the Mock Lake area. The principal deposits are at Thetford, Black Lake, Danville, and East Broughton; the first two are the most important. The mineral occurs in a series of narrow and irregular veins, sometimes, though rarely, reaching a width of six inches. Large mills are now in operation in which the rock is broken and crushed and the fibrous asbestos is taken up from screens by suction fans, and blown into settling chambers. At present the annual production is over 100,000 tons, valued at upwards of $3,000,000. It includes a large variety of grades, from the long-fibred crude asbestos, valued at $300 a ton, down to the shortest mill fibre, valued at only $2 or $3 per ton, and "asbestic sand," used for wall plaster, and valued at from 75 cents to $1.50 per ton.

In a summary of the waterpower of the world the possible horsepower of France is estimated at 4,500,000, of which only 800,000 is utilized. About an equal amount of power is available in Italy, but only 30,000 horsepower is utilized. Falls of 10,000 horsepower are abundant in the Alps. The estimate for Switzerland is incomplete, but about 300,000 horsepower is in use. Germany has 700,000 horsepower available, with 100,000 applied. Norway has 900,000 horsepower available, with a large part already developed. In Sweden there is 763,000 horsepower available, but mostly at a considerable distance from any industrial centre. In Great Britain there is 70,000 horsepower already utilized, and an equal amount in Spain. The resources of Russia are estimated at 11,[illegible] horsepower, of [illegible] been developed. The United States is credited with 1,500,000 horsepower, while Japan has 1,000,000, of which 70,000 has been exploited; and in India 50,000 horsepower has already been developed.

TESTING OF CENTRIFUGAL PUMPS.

A CENTRIFUGAL or turbine pump is not a positive displacement pump and there are no "rule of thumb" methods of arriving even approximately at its capacity. It may be, therefore, accepted that a well-equipped testing plant is one of the most important essentials for its successful manufacture.

From the manufacturer's standpoint the records of tests carefully carried out are of the utmost value. as they constitute the foundation upon which future propositions can be based, designs developed, improved and modified to suit particular requirements. From the purchaser's standpoint, on the other hand, is the absolute assurance that the hydraulic and efficiency requirements have been fulfilled and, secondly, that a trial run of several hours' duration will ensure continuous operation of the machine with no mechanical difficulties arising after leaving the works.

There are a number of testing methods in use with varying degrees of accuracy. They may be classified as follows: Weight or volume method; weir method; velocity meters. The last group includes Venturi meters, nozzles and the Pitot tube.

The instruments required, pressure and vacuum gauges to determine the total head, wattmeters to determine input to motor, or indicator to determine horsepower of steam engines, have long been standardized and are usually accepted without question by consulting engineers and representatives of purchasers on official tests; in any case their calibration is a simple matter and ready facilities are provided for this purpose. But the measurement of the quantity of water being handled presents many difficulties because the methods generally adopted, owing to their cheapness, such as weirs, nozzles, Pitot tubes and in fact all velocity meters are open to the very strong objection that their accuracy depends on constants determined by experiment which, as far as consulting engineer or official representative is concerned, may or may not be right. A means of direct measurement either by weight or volume is an absolute necessity.

In the testing plant of Canadian Allis-Chalmers, Limited, at Rockfield, near Montreal, no one single testing method is relied upon, but any one of the three abovementioned testing methods can be used and the volume method can be used to check either the Venturi meters or the weir. It may be stated here that a testing plant established at the Mather & Platt works, in Manchester, England, served as a basis for the design of this unique equipment at Rockfield.

Figs. 1 and 2 represent views of portions of the testing plant. The overall dimensions of the tanks alone are 34 ft. 6 in. long, 18 ft. 3 in. wide and 9 ft. 4 in. deep, of such proportions as are well able to cope with the largest pumping units. All tanks have been placed underground so that factory space is not wasted and the flooring made in such a way that the tanks can be easily uncovered. The total area has been divided into three tanks; the suction tank, 18 ft. 3 in. long, 15 ft. wide, 9 ft. 4 in. deep; the calibrated delivery tank, 18 ft. long, 11 ft. wide, 7 ft. 4 in. deep, and the weir tank, which is 18 ft. long, 5 ft. 9 in. wide, 7 ft. 4 in. deep. All tank walls are made of waterproofed concrete and the bottoms carefully levelled. By raising the bottom levels of delivery and weir tanks above the suction tank, they drain by gravity through connecting valves into the suction tank. A small motor-driven centrifugal pump serves as drainage pump for all tanks. Suction pipes with foot valves and strainers of various sizes are situated in the suction tank, and little time is lost in making the suction pipe connections when pumps about to be tested are bolted to the cross rails, thus providing a firm setting-up.

The discharge connections are formed by two elbows, which connect to a 6-inch and a 12-inch Venturi meter. Following the discharge pipes, they are carried to a common large pipe, which finally connects with a water switch. By removing a blank flange, a passage can be made from the delivery tank to the weir tank. On the wall dividing the delivery tank from the weir tank is located a manometer, as shown, which, by means of pipe connections to the Venturi meter tubes, registers the amount of water flowing through the tubes. Next to this

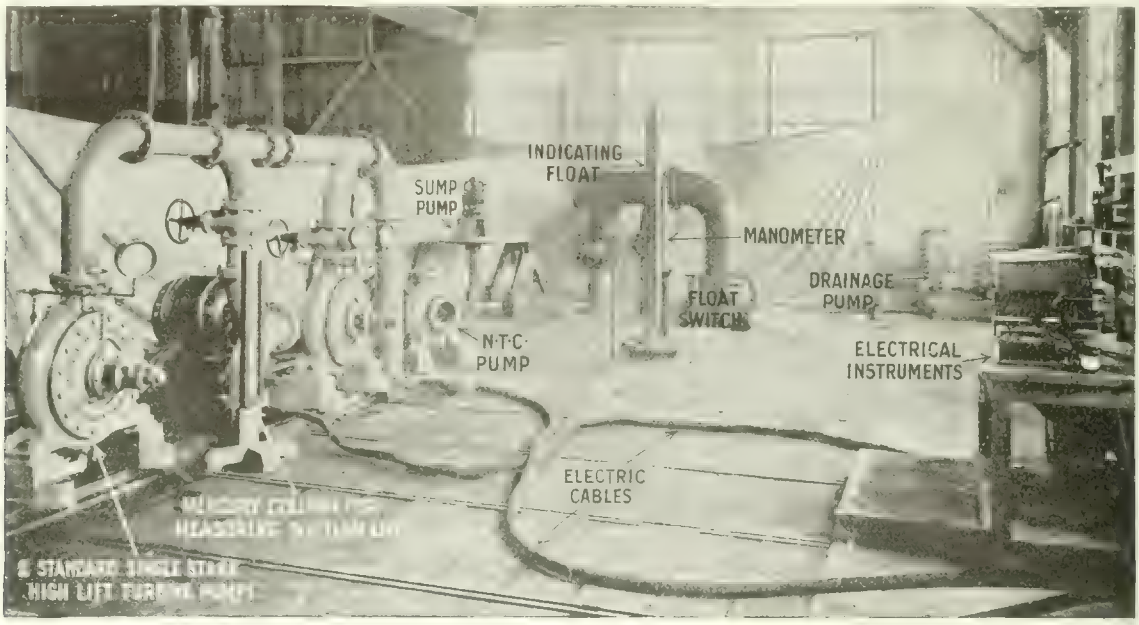

Fig. 1.

instrument is mounted a float with indicator which indicates the height of water in either delivery or weir tanks by opening and closing valves.

Referring to the weir tank, it has a cast iron weir frame, which is set in the wall dividing the weir tank from the suction tank. Weirs of the V-notch shape, and rectangular weirs of 18, 22, 24, 35 and 48-inch widths can be inserted in this frame. A ladder with a platform has been provided to allow the test operator to descend and observe the levelling and careful setting of the weir crest to the zero mark of the float scale. Baffle plates in the weir tanks can be raised or lowered in wall frames to best advantage to check any disturbances of the water and to ensure a quiet flow near the weir.

A table with the necessary electrical instruments to measure the electrical input, and engineer's desk and a fitter's bench complete the equipment.

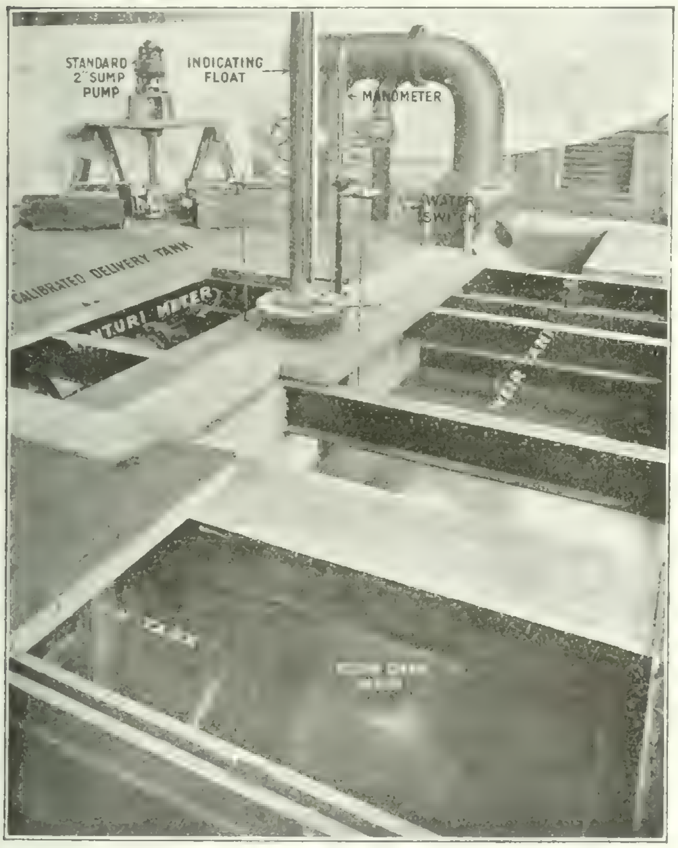

Fig. 2.

The method of test is as follows: All suction pipe connections are made with the above-mentioned pipes in the suction tank. The discharge connection is made with one of the two elbows, according to the size of pumps to be tested, and the water is discharged direct into the water switch. By operating the hand lever the water can be instantaneously switched either into the calibrated delivery tank, or into the weir flume. As the name indicates, the delivery tank, although of uniform section, has been carefully calibrated by weighing the water and noting the rise of level on the float scale. Assume the operator by means of the water switch has directed the flow into the weir flume. He observes the weir flume scale on the float and the manometer reading at the same time, thus checking the weir against the Venturi meter. Now the float is closed to the weir tank and opened to the delivery tank. The level of the water in the delivery tank having been observed and, with stopwatch in hand, the water switch lever is thrown over, allowing the water to fill up the delivery tank.

The operator allows the pump to discharge into the delivery tank for from, say, one minute in the case of 10,000 gal. per min. pumps to even half an hour if required for 500,000 gal. per min. pumps and noting the time, switches the discharge from the pump back into the weir flume whence it continues to circulate round. At his leisure and when the water in the delivery tank is quite still, the operator observes the new level and, subtracting it from the original level, arrives at an exact volumetric measurement of the water passing through the pump. Note here, also, that the water is still passing through the Venturi meters, thus checking them against the delivery tank. Thus the Venturi meter checks the weirs and the volumetric measurement checks the Venturi meter.

For any quantities over 10,000 gal. per min. the discharge is delivered direct into the delivery tank through bypass into the weir flume and over the largest weir which, having been checked up to 10,000 gal. per min., may reasonably be assumed to be exact for larger quantities.

It may also be mentioned here that steam inlet and exhaust pipe connections are available at the test plant and small or large steam turbine-driven pumps can be easily tested as motor or belt-driven units.

HYDROGRAPHIC SURVEYS IN ONTARIO.

THE stream measurement work developed in 1912 by the Ontario Hydro-Electric Power Commission was carried on continuously in 1913 with satisfactory results in the case of some rivers, and the reverse in others. The relation between gauge height and discharge was disturbed in nearly every case by ice conditions, as was to be expected. In the case of the rivers in the southwestern peninsula, such as the Grand, Maitland, Saugeen, Thames, Credit, and Nottawasaga, measurable velocities could in general only be obtained at wide shallow sections, where a high degree of accuracy in measurement could not be depended upon. The large number of mill-dams located in these streams also made it impossible to locate all gauges where they would not be affected by back-water at high stages of flow. This trouble has not yet manifested itself at the stations established on the Grand River during 1913, but it is to be expected during periods of high water.

In the case of the northern rivers, the above conditions were aggravated in many instances by the necessity of locating stations at accessible points. This usually meant the use of a bridge station, and in the case of the Sturgeon, Maganetawan, Wahnapitae, Spanish and Seguin Rivers, backwater trouble occurs intermittently owing to the operation of dams in connection with power development. The Mississaga station is seriously affected by wind levels on Lake Huron.

In the case of the Thames, Saugeen, South, Sturgeon and Credit rivers it has been found that by eliminating measurements where backwater effects are plainly evident, a fairly good station rating curve is obtainable. An effort will be made to re-locate the gauges at some of these stations so as to produce still better results.

RAILWAY TUNNELLING.

PART III.

By Leonard Goodday, C.E., M.E.

PREVIOUS articles of this series on the practical side of tunnel driving dealt with the method of procedure as followed generally in different countries. The sinking of shafts, setting out of tunnel, driving of headings, etc., were taken up in January 15th, 1914, issue of *The Canadian Engineer*. The description was continued as far as, and including in part, operations of mining and timbering, in March 19th issue, while in the following notes the discussion proceeds to the finishing of the brickwork.

From the stage at which the length under construction has been mined down to the top sill and this sill put into position the excavation must be got away quickly, as now begins the paying part of the work. Excavate down to the top of the bottom heading, placing the bars and poling farther apart. These bars may now be only a little longer than the length being mined and about 12 in. diam., one end of them being supported in the brickwork of the toothing which can be cut out for their reception, and the other end supported by temporary raking props, at a point a little back in the length from the front of the sill. About the level of the top of the bottom heading another sill is placed, the bottom of it being kept high enough to clear wagons, etc., passing through the heading. This sill is similar to the top one, but may be stronger and, of necessity, longer, because here the tunnel is nearly full width. It is placed in the same manner, letting each middle sill prop be exactly under one of those above, supporting the bars from the top sill. Two strong rakers must now be got in to support the top sill from formation, more particularly against face weight. They should be on very strong foot-blocks, and when in position, driven up tightly with driving wedges, inserted between the end of raker and the foot-block. The top end of these rakers should be formed into a jaw, to take in the bottom face angle of the sill, and should be provided with a good iron gland, just below the jaw to prevent splitting.

These top sill rakers should be got in as soon as it is possible, even before the middle sill is in, or, in any case, temporary rakers should be used. In getting out the remainder of the length, leave the sides in, and excavate the middle portion only, leaving side slopes like a cutting, and do not undermine the middle sill. Arriving at formation level, place two strong props on good foot-blocks under the middle sill, on either side of the bottom heading, and place 2 rakers to this sill, similar to but shorter than those for the top sill. The face weight is sometimes very heavy, tending to shove the sills into the length, especially when the tunnel is inverted, and in that case, besides these rakers, sill stretchers will be needed, stretching or strutting the sill ends from the last toothing. If this is not effective, "Judkin" rakers must be introduced. These are timbers abutting against one another at the centre of the sill face, and stretching it horizontally across the length to the toothing. The excavation of the slopes may now be worked, extending all to formation level across the tunnel, beginning at the top of the slope, and putting in a light bar here and there, sufficiently near to one another for them to secure the ends of any poling boards that may be required to support the ground. These bars should be supported by raking props at either end. Should the ground be good, no bars will be required below the middle sill. Do not undermine the middle sill, but leave a good footing of ground until the rest of the length is out, then take this out in bays, putting a prop under the sill from a foot-block on formation, one by one as the bays are removed.

The foundations of the side walls are usually carried down 2½ ft. below formation level and should be trenched to the net width of the lowest course of the brick footing. They must be level and solid. Any water accumulating in them can be got out by hand-pumping.

Each gang of miners should always have two faces to work, for if not, it will be idle while the bricklayers are lining. If these two faces be A and B, and the work just described as having been done in A face, while the mining of this length is going on, and before it is finished, the bricklayers should have commenced and keyed the arch of the length last got out in B face. Directly they have keyed it, some of the miners' gang in A should begin to drive the top heading for another length in B. They should be able to get the 5 bars drawn into that length before that in A is finished. There is then about room for the whole gang to get to work in this next length in B face.

By the time a few lengths are finished, it is likely that a good deal of water has been tapped, and that the method of emptying the sump by barrel is not sufficient. A steam pump is really the best and cheapest means to install. One of these occupies little space, and can be fixed in a manhole in the side wall of the tunnel, near the bottom of the shaft, and locked up. The force pipe is conducted up the shaft, and the suction into the sump, with a branch along the side wall to near the length that is being mined. To this latter can be attached a flexible hose. A stop-cock should be fitted to each branch of the suction, so that communication can be cut off from either pipe. The steam for the pump can be supplied from the winding engine's boiler.

Lining the Length.—Having the wall foundations out, everything is ready for setting the side wall frames.

The engineer should put a centre line point accurately in the middle sill, and mark off the face of the walls, and by driving a spike into the timber at any point above rail level properly distanced from the centre line. Set up the frame with its back edge against this spike, and plumb it. The projecting piece of timber marking rail level must be precisely levelled to rail level. Spike this frame securely, its place being at the leading end of the length, and close up to the sill. Put the frame up for the other wall in the same way. Four of these frames will be required for a first side length.

Bricks and mortar are now required in the length. It may be inconvenient to supply them from the open ends for all the faces, because of the number of these faces at work and the traffic in and out of the tunnel. When 8 or 10 lengths have been turned at any face, a turn-out should be put in off the main track, i.e., a siding where wagons can stand and allow others to pass them. For a tunnel of this length a mortar mill can be used in each of the entrance cuttings.

A gang for lining a length is made up of 4 bricklayers and 6 laborers—half the number being on each side and each party working on the same side of the tunnel for all lengths—so that their work will be similar throughout. The best one usually takes the leading end or toothing of the length on his side. The term "toothing" denotes leaving the bricks at the leading end projecting every alternate course, as the bond causes them

to be laid, and they then form a bond for the next length. Some prefer every length to be finished up squarely. It has a neater appearance, and is quite as strong as bonding one length into another.

A length should be complete in itself, and as one length is lined a few days before the next is commenced, there is time for settlement. If the bricks in this first length are tooth, the next, when built to it, settles also, tears out of the toothing, and becomes broken. This has to be patched, is unsightly, and suggests weakness.

Again, the courses may not be started at the same level as the last, and to get the bricks into the last toothing a little squeezing takes place, the consequence being that the first three or four bricks in every course of the new length are found to be running up or down out of the general level. A block toothing is best where bricks are used for lining. Stone side walls are another matter.

English bond is best for side walls. The first course of all wall footings may be laid dry, and the footings should have half brick projection every two courses in height. In heavy ground, however, portions of these footings are carried up plumb to formation level, i.e., full width of bottom course.

On these solid "stick-ups" set the sills and props for supporting the centre ribs. Before the wall is at rail level the courses must be level (except in the case of a gradient). At rail level leave a projecting brick near the leading end as a guide and reference. Now stretch a line from the saw cut in the wall frame, marking the courses to the corresponding course of the last length. Continue this procedure following the courses marked on the frame until springing level, the top of the frame, is attained. Grout every course and flush every joint. As the brickwork proceeds, all cavities between the back work and the mined ground must be carefully filled and packed solid.

The walls should be built up without interruption until complete to springing level, after which the centres or ribs are set. The ribs for a 5-yard length are, as mentioned before, three in number, viz., two intermediate and one leading.

The leading rib must be so placed that the laggings provided (15 ft. x 7½ in. x 2½ in.) will reach and fit between the groove or projecting sweep in the rib under the last toothing and on the one now being put up. Fix the ribs together by spiking pieces of plank upon their under sides, and drive up the slack-blocks until the crowns of the ribs are all level, and about 1 in. over sight to allow for after settlement in the work. All the necessary laggings required must be in readiness on the scaffolds standing under the last length.

One lagging is placed on each side at the arch-springing. The bricklayers put on lagging by lagging as they require them as the brickwork progresses.

The laggings will not bear on the ribs in places, when the latter have been used several times; in such cases it is necessary that wedges be used under the laggings, to keep them up to proper line, and to allow of no sagging or springing.

When the underside of the lower bar is reached, 2 laborers may then do the packing and help getting these bars out, which is done with the aid of tackle. To get a bar out it is raised a little, so that another course of brickwork can be got in to secure the ends of the poling boards that will be released by the bar. In heavy ground nearly all of the boards round the arch must be left in behind the brickwork to keep the ground from "running." When the ends of the boards are secured, the bar can be lifted out of its place, and turned round until it can be got through a bay of the ribs, and back upon the scaffold under the last length. This is often hard work where many ribs are needed, and the nearer the crown the more crowded it becomes. For the arch, English bond for the brickwork is often insisted upon, while some prefer single-ring work, i.e., all bricks laid as stretchers with bonders of headers where possible, and which is good, securing better work and less mortar used. The more bricks and less mortar there are in such a piece of work, the better the work, providing there is enough mortar to properly bed the bricks. A ¼-in. joint on the soffit, if properly radiated from the centre, will be much thicker at the extrados of the brick, and must be so if the courses are to radiate. Care must be taken, so as not to overdo this, for if there is an excess, there will be a greater settlement afterwards, and in a wet tunnel the mortar gets washed out, reducing the safety of the arch.

Returning to lining the length, the arch is built up level with the top sill, when a bricking-in piece must be introduced. It has been shown that before the top sill could be got in the bars above it had to be back-propped ahead of it, as the brickwork cannot be built further forward than the sill, and as all bars must come out as drawn sooner or later. It follows that there must be a few feet of mined ground ahead of the toothing now being formed, poled with boards, but without support. When the bars are drawn out bricking-in pieces about 8 ft. 0 in. x 6 in. x 6 in., are placed behind the brickwork between each two bars, about 3 ft. of their length resting on the brickwork and the remaining portion projecting along the roof of the mined ground ahead. They are securely packed from the brickwork before the bar is taken out, and they will then hold up the poling boards and ground.

The seventh bars are the last taking out bars. Before getting up to this height, a temporary scaffold must be made above the main one.

When the bars are all out, bricking the arch continues under the drawing bars.

The last lagging which has been put on each side must be grooved on its top edge about 1 in. deep and the length of the lagging on which rest the block lagging, which are pieces of board 1 in. thick at the ends, 2 in. thick in the centre and about 3 ft. long, used for building the key. They are laid transversely to the other laggings.

At this stage the work is very arduous and comparatively slow progress is made. Generally speaking, 55 hours is an average time in which to line a 5-yard length. It can be done in about 42 hours, however, if a full gang is kept steadily on the work. This is, on the whole, rather uneconomical as when the brickwork approaches the key of the arch working space is badly curtailed. Better practice is to withdraw the gang of men on one side until the other side has finished up to the key or within about 1½ ft. of the crown. Then the other side is finished with greater ease and better workmanship.

The brickwork completed, the bars are drawn and operations continued on the next length.

After several hundred feet of tunnel is thus completed at any face, the centre drain should be built in. In size a drain 18 x 12 in. wide is generally sufficient. The bottom should be of 4-in. flag stone, and the sides of brick or flat bedded stone laid dry. A 6-in. flag stone bedded in mortar but with joints open forms a satis-

factory cover. Its top should be at formation level, and the formation should rise from this flag towards the side walls of the tunnel, this rise to be about 6 in.

Bench marks should be plainly indicated opposite one another on the side walls, from which the height of the soffit at various points may be ascertained soon after the arch is turned. By renewing these measurements, any sinking or settling of brickwork can be noted.

REVISION OF UNITED STATES ROAD LAWS.

ROAD laws which have been on the statute books of various states of United States for more than one hundred years will probably be repealed as a result of the movement which has been inaugurated by the American Highway Association in conjunction with the American Bar Association. The committees appointed by the two associations have had prepared through the co-operation of the U.S. Office of Public Roads a complete literal compilation of the road laws of all the states, as well as the laws relating to indebtedness, the use of convict labor, and various other subjects which have a bearing upon the management of the public roads. An index chart for these various laws is now being prepared and as soon as it is completed the committees will determine upon the lines along which revision will be sought. The governors of the various states will then be asked to recommend to the legislators the appointment of special committees to confer with these committees with a view to adequate revision of existing road laws.

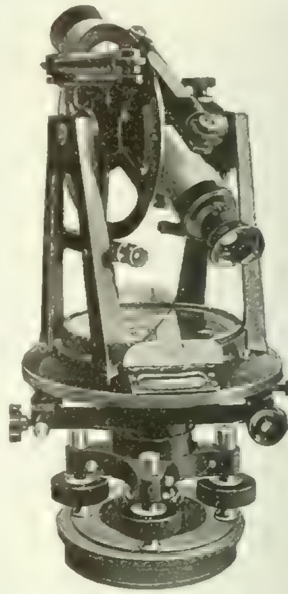
The first step in the revision of the state road laws will be to recommend that all obsolete, useless, or unnecessary road laws be repealed. The next step will be to simplify and arrange in logical order the existing necessary road laws. It has been found that in some of the states an accumulation of road laws running back over 100 years exists thus creating almost hopeless confusion. Certain basic features of good administration will be urged by the joint committees such as the payment of road taxes in cash; the elimination of a multitude of unnecessary road officials now characteristic of many of the states; the requirement of skilled supervision in the actual construction and maintenance of roads by providing qualification tests; the constant employment of highway engineers or superintendents; the adoption of the appointive rather than the elective method for such officials; the substitution of continuous maintenance for the present intermittent method; the proper utilization of convict labor where climatic and other conditions warrant its use on the public roads for the preparation of road materials; the general adoption of the principle of state aid and supervision; the proper safe-guarding and accounting of road funds.

Wherever practicable, uniformity among the road laws of the various states will be urged by the committees as it is realized that the traffic is now controlled by economic conditions rather than by state lines and should not be hampered by conflicting laws of the various communities.

It is expected that a most interesting report will be made by the joint committees at the Fourth American Road Congress which will be held at Atlanta, Ga., November 9-14, 1914.

A NEW TRANSIT.

A new transit, called the "C. E. De Luxe," is being built by E. R. Watts and Son, Canada, Limited, of Ottawa. Among the interesting features appearing in the specification for this instrument, illustrated herewith, are the following:—



Horizontal Circle—Five-inch diam., reading to 30 seconds, graduated with two rows of figures, 0—360, both ways. One row of figures with the corresponding vernier is filled in with red, while the other row and vernier are filled with black.

Bubbles—The plate bubbles are enclosed in the compass, but are adjusted outside the compass by means of capstan headed screws.

Telescope—The telescope is made by Carl Zeiss, of Jena, and is fitted with their patent internal focusing arrangement, which gives absolutely accurate readings without the use of a constant.

Foot-Screws—The foot-screws are threaded on hard German silver, whilst the milled heads are made of hard rubber. The former admits of a fine thread and an easy motion. The hard rubber millings allow of a larger diameter head without increasing the weight, and are advantageous in extremely cold temperatures.

Tangent Screws—All tangent threads are cut in German silver. The upper plate, clamp and tangent screw milled heads are of a different shape to the lower clamp and tangent screw milled heads. This enables the observer to distinguish by touch which clamp and tangent he is using, whilst to further facilitate this point they are placed in such a position that even when wearing heavy mitts their distance from the plate denotes, without having to take the eye from the telescope, which clamp and tangent is being used.

A London engineer has recently compiled figures in an endeavor to throw light upon the vexed question of whether motor traffic is more injurious to road surfaces than is ordinary horse-drawn traffic. He takes as a basis of comparison the horse traffic periods of 1905-1906, and the motor traffic periods of 1911-12 which shows a decrease in annual cost per mile of roadway, for cleansing and scavenging, in the following six London districts: Battersea and Chelsea, $540 per mile; Fulham, a decrease of $5.30 per mile; Paddington, a decrease of $620 per mile; Wandsworth, a decrease of $470 per mile, and Westminster a decrease of $895 per mile. A particular case of saving in up-keep cost is given in the example of a macadam road between Hammersmith and Barnes, which went on pieces under motor traffic. The Barnes district council spent $47,000 in relaying this stretch with block paving, and a tabulation of expenses shows that not a single penny has been spent since then in repairs to the block paved road, although the motor traffic has increased at a very heavy rate. During the horse traffic period the cost of maintaining the macadam road was $5,750 in 1906, and $1,915 during the early part of 1907, in which year the roadway was relaid.

Coast to Coast

Guelph, Ont.—The financial statement of the water commissioners at Guelph for the month of March shows a balance of $3,418.96.

Fort George, B.C.—The last spike on the G.T.P. was driven on April 7th, at the east end of the bridge over the Nechaco at Fort Fraser river.

Toronto, Ont.—The net surplus for the Toronto Hydro-Electric system in 1913 amounted to $34,576, or approximately 3 per cent. on the total investment.

St. Thomas, Ont.—The St. Thomas board of works estimates its expenditure for the current year at $19,900, which is about the same as required last year.

Victoria, B.C.—The outcome of the consideration by the Victoria council of estimates for 1914 is that the aggregate amount to be raised has been placed at $2,460,000.

Brantford, Ont.—Civic estimates for this year at Brantford provide for a total expenditure of $539,465, as compared with $472,579 last year, showing an increase of $66,886.

Montreal, Que.—Latest advices from headquarters at Montreal state that the $1,000,000 station and office building of the C.P.R. at Vancouver will be ready for opening in June.

Regina, Sask.—A new generator at the new power house at Regina has been installed, and is working satisfactorily; while another generator, which will be powerful enough to carry the whole of the lighting system of the city of Regina, is reported to be on its way.

Winnipeg, Man.—The statement has been made by Morley Donaldson, vice-president and general manager of the Grand Trunk Pacific Railway company, that the last spike on this second transcontinental railroad in Canada will be driven and the last rail will be laid on April 9.

Fredericton, N.B.—The conclusion concerning the harbor at L'Etang, reached by Mr. A. D. Swan, M. Inst. C.E., M. Inst. M.E., M. Can. Soc. C.E., who has furnished a report to the Federal Department of Public Works on ports in Charlotte county, N.B., is that this port would not be suitable for the largest class of modern merchant vessels, but, if desired, it would make an excellent harbor for steamers of moderate size.

Hamilton, Ont.—The cost of Hydro-Electric street lighting at Hamilton has now been estimated at $88,125 for one year, as compared with $65,800 previously estimated. The increase is due to extra cost of corner lights, increased area to be lighted, and the Ontario commission's decree to increase the cost. When the Hydro's $88,125 system is running complete, there will be 9,100 lights, giving a total of 1,320,000 candle-power, evenly distributed.

Halifax, N.S.—On March 24, a bill was introduced in the Nova Scotia legislature to incorporate the Nova Scotia Tramways and Power Company, which is to have a capital of $5,000,000 with power to increase it to $10,000,000. It is also provided that the bill authorizes the company to purchase the Halifax Electric Tramway Company. Moreover, the Nova Scotia Light and Power Company agrees to transfer to the new company all its rights in certain power sites and lands at Gaspereaux.

Moncton, N.B.—The I.C.R. is now constructing 165 new bridges along the lines in the eastern provinces, while by October 30 new 35-ton passenger locomotives will be put into commission. A section of road from Pasaic Junction to Oxford, 70 miles long, will also be double-tracked by that time. Another project of the new I.C.R. head is that of utilizing the short line between Pictou and Oxford Junction for Sydney freighting. This will necessitate bridging across the West, Middle and East rivers of Pictou to overcome the Westville grade.

Yorkton, Sask.—Recently at Yorkton, what may prove to furnish an adequate water supply for the town has been discovered. A supply has been struck in a test well now being dug by the town, which promises to develop into a flow amply adequate for all requirements for years to come. The new test well is 6 feet in diameter, and at a depth of 35 feet the flow of water was struck. It is now proposed to sink a 15-foot well, 50 or 60 feet; and it is confidently predicted that this will produce a water supply sufficient for a city with five times the population of Yorkton.

Kamloops, B.C.—The vertical lift span in the C.N.R. company's new girder bridge, just completed across the North Thompson river, consists of a 93-foot deck plate girder, weighing about 236,000 pounds, which is balanced by counter weights attached to cables which pass over sheaves at the top of the towers. The span is raised and lowered by means of cables fastened at the top and bottom of the towers. These cables pass over drums at each corner of the span, which are actuated by a system of gears and shafts connected to a gasoline engine at the centre. Hand operation is also provided. The machinery is designed to lift the span 53 feet in 100 seconds, providing a clearance of 55 feet above high water.

Prince Rupert, B.C.—The construction work which has been accomplished by the G.T.P. Railway company along the banks of the Skeena river to its terminus at Prince Rupert is said to be one of the greatest of railway engineering achievements. For a 200-mile section of railway, millions of dollars were spent before a shovelful of earth was removed. But along the banks of the Skeena a route has been hewn free from sharp curvature or steep grades, despite the rugged contour of the river's course, and there is no danger of the turbulent river ever being able to disturb this roadbed. Very little tunnelling has been done, for nearly 4,000,000 cubic yards of rock were blown away on 186 miles of line between Prince Rupert and Hazelton to make a route through the Cascades.

Regina, Sask.—The new reservoir to be constructed at Regina is to be a replica, with trifling exceptions, of the 5,000,000-gallon reservoir at Tor Hill. An 18-inch supply main from Tor Hill reservoir is to be laid along Halifax street, while a 42-inch main between the reservoir and the power house will be constructed on Osler street. Arrangements are also being made to connect the new basin with the proposed 27-inch supply main when the latter is constructed in 1915 or 1916. The reservoir will hold a depth of 25 feet of water and will be constructed 20 feet above the surface of the ground. It will contain nearly 500 tons of steel; will be covered with a concrete top and above the concrete a 12-inch layer of soil. In this latter respect it differs from the Tor Hill reservoir, which has no earth covering. In order to hold the earth it is proposed to plant grass seed on the top.

Regina, Sask.—The Regina incinerator was put into full operation a few weeks ago. It has been erected at a cost of $65,000, has a capacity of 110 tons of garbage per day, and has two furnaces. There are two large boilers in the plant, fans for inducing draft and for drawing off the gases, which are used to heat the boilers and create steam, etc. The steam is forced through pipes in the main furnaces, and as the damp garbage is dropped down on the grates and steam pipes, it is dried out considerably and ignition induced. Once the fires are fairly hot, the fans keep the draft in such condition that the fire burns fiercely, and it is easy to keep a steam pressure of 60 to 100 pounds on the boilers, or

enough to run the fans and a complete electric light plant of sufficient capacity to light all the buildings at the disposal works. At the present time it is only necessary to run one furnace at a time, in order to take care of all the city's garbage.

Vancouver, B.C.—The creosoted wharf to be constructed at the site of the proposed Marine and Fisheries building on the Soughees Reserve, for which the contract has just been let to Messrs. Parks, Tupper and Kirkpatrick, of Vancouver, will be 420 feet in length; and on the north side it will run inshore 224 feet. It will be 50 feet wide and will be 6 feet above high water mark. A considerable amount of dredging has been carried out during the past few months in order to give 20 feet of water at low tide; and the foreshore will be graded to a uniform level, giving a gradual slope toward the wharves. On the graded site it is proposed to build the new Marine and Fisheries Depot. The contract calls for the excavation of 27,000 cubic yards of material, composed mostly of clay. It is probable that the whole of the grading will be completed within six weeks after an actual start on the work. The wharf should be completed within four months, and before the expiration of that time it is probable that the contract for the Marine and Fisheries building will be awarded.

Edmonton, Alta.—The final plans recently filed for the route of the Canadian Northwestern railway, or the C.N.R extension into the Peace River district of Alberta, show that from Whitecourt, to which point at the confluence of the McLeod and Athabasca rivers the grade has been completed, the line will follow the valley of the Athabasca for about 50 miles on the south side, crossing the McLeod by a separate bridge. It will cross the Smoky river about 3 miles from the [illegible] of Grande Prairie, between Saskatoon and Bear Lakes. After crossing the Athabasca and leaving the valley for the north the route goes through township 62, range 18, townships 63, 64, and 65, range 19; township 66, ranges 20 and 21; township 67 and 68, range 22; townships 68 and 69, range 23; townships 69 and 70, range 24; township 70, ranges 25 and 26; township 71 and as far west as range 6, west of the 6th meridian; township 72, ranges 7 and 8; township 75, ranges 9 and 10; township 74, ranges 11, 12 and 13, to the Alberta-B.C. boundary.

Toronto, Ont.—Over a million dollars of the five million good roads grant by the Ontario government has already been expended in the north, according to the report which J. F. Whitson has submitted to the legislature, through W. H. Hearst, minister of lands, forests and mines. In this outlay, which reaches exactly $1,081,172.28, road construction of 764 miles has been completed during the past year. In all, 279 miles of bush roads were cut, the most of which are in the district of Temiskaming, in the vicinity of Cochrane, Porcupine, Iroquois Falls, from the Quebec boundary, 125 miles to Ground Hog; also a 50-mile strip from Haileybury to Englehart, Matheson, Charlton and Swastika. Mining roads were also extended into the Kirkland Lake Goldfields and Shining Tree. The estimated expenditures for 1914 amount to $950,000, of this Rainy River gets $85,000; Port Arthur, $60,000; Fort William, $90,000; the Soo-Sudbury road, $90,000. The largest individual grants go to the T. and S.N.O. and T.N.R. districts, these receiving $120,000 and $105,000, respectively.

Edmonton, Alta.—Route plans for 18 miles of the Central Canada Railway north of Edmonton have just been filed in the provincial department of railways for Alberta. These show that 60 steel and wooden bridges, ranging from 75 to 125 feet in length, will be required on the line, which will connect with the Edmonton, Dunvegan, and British Columbia railway at Round Lake, and will continue along the North Hart river to Peace River Crossing. It is also stated by the railway engineers that at least 50,000 yards of earth will have to be removed from every mile of line on the right-of-way along the North Hart river; and it is estimated that the construction cost of this stretch of line will be more than $50,000 a mile. The sliding banks along the tortuous windings of the North Hart river are fully 700 feet above the high water level. The grade drops that distance in the 18 miles of line before reaching Peace River Crossing, where the railway company will span the Peace River with a steel bridge costing $400,000. Thence the line will continue to Dunvegan along the north bank of the Upper Peace River.

PERSONALS.

C. B. CARTER, for two years municipal engineer of West Vancouver, has resigned.

A. J. DONEGAN has been appointed superintendent of the Algoma Eastern Railway, with headquarters at Sudbury, Ont.

E. I. SIFTON has been appointed general manager of the Hamilton Hydro-Electric System, and W. H. CHILDS will be his assistant.

C. M. ARNOLD, formerly city engineer of Lethbridge, has resigned his position with the Canadian Pacific Railway, as engineer of ditching operations in Alberta.

J. E. PENNYBACKER, who has been advisory expert for the Ontario Highway Commission, has resigned as secretary of the American Highway Association to accept the

J. E. Pennybacker.

position of Chief of the Division of Road Economics in the Office of Public Roads, United States Department of Agriculture.

HERBERT DOUGLAS, lately of the mechanical department of the Canadian Pacific Railway Company, and formerly foreman of the erecting department of the Consolidated Mining Company at Trail, B.C., has received the provincial government appointment of assistant inspector of factories for British Columbia.

L. P. BURNS, A. SCULLY and J. T. LENNOX, president, secretary, and a director, respectively, of the Inland Construction Company, Limited, of Toronto, who recently secured the contract for the Swift Rapids section of the Severn river division of the Trent Canal, were in Lindsay last week following up their plans for undertaking the work. It is announced that Ragged Rapids will be made headquarters, and that a road will immediately be built from there to Swift Rapids.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page [illegible], a directory of such societies and their chief officials.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

At the monthly meeting in Montreal of the Canadian Society of Civil Engineers on April 9th Mr. L. S. Bruner, of the Canada Cement Company, read a paper, entitled "Concrete Road Construction," and Mr. G. Henry, chief engineer of the Highways Department of Quebec, presented one on "Road Improvement in the Province of Quebec."

Mr. Bruner's was a most interesting address, illustrated by lantern slides showing types of roadway construction and illustrating the use of concrete to good advantage. Among others were views of the King Edward Highway, which, it is planned, will be officially opened during the Canadian and International Good Roads Congress in Montreal, May 18th to 23rd.

Mr. Henry's paper was read by Mr. R. A. Ross. It pointed out that in Quebec there were 45,000 miles of roads, including the mud tracks and trails of the colonists, the latter being little more than navigable and received very little traffic. Next to them were the by-roads, made of graded earth, which for a long time to come would need nothing but grading and draining. These were followed by the class of roads, which required artificial surfacing in order to meet traffic requirements, while the final class was the series of trunk roads or provincial highways connecting with big cities.

Mr. Henry stated that with the widespread system of roads in the province and the enormous amount of work to be done, the cost of improvement would mount so high that the present generation could hardly hope to see much improvement. The best that could be hoped would be for the improvement of the most-needed roads during the next few years. The general idea was that such work as was possible should be done on the ordinary roads, while the highways "de luxe" should either wait their turn or pay for their accommodation.

He warmly recommended the efforts of the Provincial Government to extend the work on highway improvements, especially advocating the straightening out of provincial roads so that a railroad crossing the same distance on either side should be at least 3,000 feet. A rather surprising feature of his address was the fact that the average annual period for such road work in this province was only 100 days, the rest being used up by winter and rainy days. The general conclusion was that the ancient system of statute labor and the "share system" should be dropped in favor of the municipally organized road building system.

Mr. H. H. Vaughn was chairman of the meeting.

"OIL SEEPAGES IN BRITISH COLUMBIA."

This was the subject of an address given recently by Mr. F. J. Crossland to the Vancouver Chamber of Mines. Owing to the desire of the British Government to secure an adequate and well-distributed supply of oil for naval use, the subject is one of great interest in the Province. The well-established oil fields of Mexico and California and the indications that are in evidence northward, have acted as a stimulus to oil investigations in British Columbia. Mr. Crossland stated that it was the intention of the Dominion Government to send a corps of experts to British Columbia this season to conduct exhaustive examinations of the carbonaceous deposits.

TORONTO SECTION A.I.E.E.

The fifth regular meeting of the Toronto Section of the American Institute of Electrical Engineers will be held in the Engineers' Club on Friday evening, April 17th, 1914, at 8.15 p.m. Mr. C. G. Spencer, Mechanical Engineer of the Toronto Power Company, will present a paper, entitled "Standby Steam Stations for Overhead Transmission Systems."

CANADIAN FORESTRY ASSOCIATION.

The officers for the current year of the Canadian Forestry Association are: President, William Power, M.P.; vice-president, F. C. Whitman; secretary, James Lawler, Journal Building, Ottawa.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Diven, 47 State Street, Troy, N.Y.

AMERICAN HIGHWAYS ASSOCIATION.—**Fourth American Road Congress to be held in Atlanta, Ga., November 9-13, 1914. J. E. Pennybacker, Secretary, Colorado Building, Washington, D.C.**

AMERICAN PEAT SOCIETY.—**Eighth Annual Meeting** will be held in **Duluth, Minn., on August 20, 21 and 22, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.**

AMERICAN SOCIETY FOR TESTING MATERIALS—**Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-**Treasurer, **University of Pennsylvania, Philadelphia, Pa.**

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—**To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.**

CANADIAN FORESTRY ASSOCIATION.—Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal.

The American Railway Engineering Association's annual convention was held at Chicago, Ill., March 17-20. The committee reports dealt with included those on rules and organization, signals and interlocking, yards and terminals, roadway, wooden bridges and trestles, iron and steel structures, masonry, track, electricity, wood preservation, grading of lumber, water service, buildings, rail, ties, signs, fences and crossings, conservation of natural resources, economics of railway location, uniform general contract forms, records and accounts, and ballast.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21565—March 2[illegible]—Authorizing G.T.R. to construct siding into premises of Canadian Buffalo Forge Co., Limited, on Lot 18, city of Berlin, Ontario.

21566—April 1—Approving Montreal and Southern Cos Ry., Co.'s Standard Freight Tariff C.R.C. No. 1; to become effective on April 13th, 1914; said tariff with copy of this Order to be published in at least two consecutive weekly issues of Canada Gazette.

21567—March 31—Authorizing Cedars Rapids Manufacturing and Power Co. of Montreal to take additional 25.8 ft., property of Joseph Bissonnette, parish of St. Joseph de Soulanges, Co. of Soulanges, Que., for its transmission line.

21568—April 1—Authorizing Lake Erie and Northern Ry. Co. to construct bridge across Lynn Pond and Lynn River, at Simcoe, Ont.

21569—March 31—Authorizing C.P.R. to construct bridge No. 19.86, on Farnham Subdivision, Eastern Division, across Richelieu Street, town of St. Johns, Que.

21570—March 30—Authorizing C.P.R. to construct spur for International Linseed Oil Co., at Moose Jaw, Sask.

21571—March 30—Authorizing C.N.R. to construct extension of spur, already constructed, to gravel pit, Lot 45, Tp. McIrvine, Rainy River District, Ont., and to cross Government Colonization Road and Rainy River Road in said Lot 45.

21572—March 31—Approving location C.P.R. station in Lot 17, Con. 7, Tp. Mara, Co. Ont., Ont., at Schepler, mileage 51.4, on Port McNicoll Subdivision, Ontario Division.

21573—March 28—Authorizing C.L.O. and W. Ry. (C.P.R.) to take, without consent of owner, certain lands for purpose of affording access to station grounds in town of Oshawa, Ontario.

21574—March 30—Authorizing Cedars Rapids Manufacturing and Power Co. of Montreal, to take additional 28.9 ft. for transmission line, across Lot 142, parish St. Joseph de Soulanges, Co. Soulanges, Que., property of F. X. Menard.

21575—March 30—Authorizing Cedars Rapids Manufacturing and Power Co. of Montreal, to take additional 25ft. for its transmission line, across Lots 309, 310, property of Francois Valade, and Lot 14, property of Mrs. J. A. Lerous, parish of St. Joseph de Soulanges, Co. Soulanges, Quebec.

21576—April 1—Granting leave to Midland Ry. Co., to lay pipes under industrial tracks of C.P.R., lying between Erin and Clifton Streets, city of Winnipeg, Man.

21577—March 31—Approving location and design of G.T.R. proposed new station at Edfrid, Ont.: Provided, whenever traffic on highways is blocked for more than five minutes, at any one time by reason of location hereby approved, Board shall be at liberty to re-locate said station.

21578—March 31—Directing that within 90 days from date of this Order G.T.R. install improved type of automatic bell at first public highway west of South Indian, Station, Ont.

21579—April 1—Relieving G.T.R. from providing further protection at crossing of 2nd highway east of Carlsbad Springs, Ont.

21580—April 2—Authorizing C.P.R. to reconstruct two bridges—namely, No. 24.0, Brockville Subdivision over Irish Creek, near Jaspar, Ont., and No. 2.9, Fredericton Subdivision, over Three Tree Creek, near Fredericton Jct., N.B.

21581—April 2—Authorizing Cedars Rapids Manufacturing and Power Co. of Montreal, to take additional width of 25 ft. across Lots 126 and 123, property of Victor Juillette, and Lot 129, property of Hormisdas Legros, parish St. Ignace du Coteau du Lac.

21582—April 2—Approving location C.P.R. station at [illegible], B.C., [illegible] Kootenay Central Railway.

21583—April 2—Ordering and Declaring that Bank of [illegible] New Westminster [illegible] is authorized and re[illegible]quired to pay to G.N.R. or its order sum of $1,222.50 deposited by Delta Shingle Co., Limited, to order of Board under Order No. 18508.

21584—April 3—Authorizing C.P.R. to construct spur for Fernie-Fort Steel Brewing Co., Limited, Fernie, B.C.

21585—April 2—Authorizing C.P.R. to use and operate bridges—namely, Red River Bridge, Winnipeg Terminals; No. 0.41, Fort William Terminals; 131.3, Brandon Subdivision, and 63.3, Lac du Bonnet Subdivision.

21586—April 2—Authorizing C.P.R. to construct spurs (1) for the Manley and Slater Automobile Co., Moose Jaw, Sask., (2) Canadian Standard Automobile and Tractor Co., Limited, Moose Jaw.

21587—April 3—Authorizing T.H. and B. Ry. to construct spurs in city of Hamilton, Ont., for Hamilton Bridge Works, Co., Limited.

21588—April 3—Approving C.N.Q.R. plan showing proposed arrangement of signals at crossing of C.P.R., at L'Epiphanie, Que.

21589—April 3—Authorizing Point aux Trembles Terminal Ry. to construct across Notre Dame Street, east on Island of Montreal, parish of Pointe aux Trembles, Que.

21590—April 3—Suspending C.P.R. Co. Tariff, C.R.C. No. E. 2765, and G.T.R. Tariff C.R.C. No. E. 2896, covering proposed new rules governing milling-in-transit of grain, pending investigation by Board.

21591—April 4—Amending Order No. 21558, March 26, 1914, by striking out the words, "National Steel Car Company, Limited," and substituting therefor the words, "Dominion Power and Transmission Company, Limited."

21592—April 3—Authorizing, upon certain conditions, the Pointe aux Trembles Terminal Ry. Co., to construct its lines and tracks across the lines and tracks of the C.N.Q. Ry., in the parish of Pointe aux Trembles, P.Q.

21593—April 2—Authorizing the G.T.R. to construct certain bridges on its line of railway.

21594—April 2—Requiring G.T.R. to flag all train movements over crossing of Bridge Street, Niagara Falls, Ont.

21595—April 2—Relieving, for the present, the G.T.R. from providing further protection at the crossing of Light Street, Woodstock, Ont.

21596—April 4—Authorizing the Can. Nor. Alta. Ry. to construct its line of railway across and divert the North and South Road Allowance, in Sec. 31, Twp. 54, Rge. 27, W. 4 M., Alta., at mileage 15.0.

21597—April 3—Ordering the C.N.O. and the C.L.O. and W. Rys. to widen out the approaches at Mary Street to 24 ft. and provide protection fences; to widen approaches at James Street to 24 ft., and to construct sidwalk on west side of crossing, in the city of Belleville, Ont.

21598—April 6—Amending Order No. 21457 by striking out the word "Ontario" under the heading "Province" in the operative part of the Order and substituting therefor the word "Quebec."

21599—April 1—Authorizing Cedar Rapids Manufacturing and Power Company to take lands O. Leroux, G. Methot, H. St Denis, and L. Brisbois in the Co. of Soulanges, Que.

21600—April 6—Authorizing the C.P.R. to construct a branch line for M. M. Cummings, Westboro, Ont.

21601—April 6—Authorizing C.P.R. to construct road diversion in Con. 16, Twp. 2, Rge. 15, W. P. M., Man., by grade crossing.

21602—April 6—Authorizing C.N.O.R. to cross Davenport Road, Toronto, by means of structure carrying highway over the railway.

21603—April [illegible]—Authorizing C.N.O.R. to cross St. Clair and [illegible] Avenues, Toronto, by means of structure carrying the highways over the railway.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

ROGER'S PASS TUNNEL OF THE C.P.R.

THE FIVE-MILE, DOUBLE-TRACK TUNNEL UNDER CONSTRUCTION THROUGH THE SELKIRK MOUNTAINS, LOWERING THE GRADE 540 FEET AT THE SUMMIT AND REDUCING THE DISTANCE BY 4½ MILES—NOVEL METHOD OF CONSTRUCTION EXPLAINED.

THE Canadian Pacific Railway is now constructing one of the most important engineering works ever attempted on this continent—the boring of a 5-mile, double-track tunnel through Mount Macdonald, one of the peaks in the Selkirk Range. The purpose of it is to obviate the present necessity of using two long spiral loops on the western slope, and many miles of snow sheds, the improvement being designed to effect a considerable grade reduction and the abandonment of what is considered from the operating standpoint one of the most costly sections of railway on the entire system.

Fig. 1.—Approaches to the Roger's Pass, showing (on the left) Mt. Macdonald and (on the right) the Illecillewaet Valley, British Columbia.

The tunnel, when completed, will be the longest in America, measuring exactly 26,400 feet, and surpassing the Hoosac tunnel on the New York Central line, the longest at present, by three-quarters of a mile. It has associated with its construction, the building also of over 18 miles of new main line. The views shown in Fig. 1 illustrate the nature of the region it penetrates, while the map and profile (Figs. 2 and 3) show its relative position and that of the old and new main lines of the Canadian Pacific Railway through the Selkirks.

Since the C.P.R. first opened its transcontinental line through the mountains of British Columbia it has expended millions of dollars in protecting and renewing its tracks, on extra locomotives for the heavy grades, and in coping with snowfalls and other physical handicaps which keep a large force of men and a large amount

of expensive equipment busy nearly all the year. At Roger's Pass, close to the summit of the Selkirks, the company maintains large engine sheds, shops, snow-ploughs and outfits ready for service on both sides of the Selkirk range.

For many years the company has been gradually effecting a reduction of its gradients and improving its main line generally in preparation for the development of the grain traffic westward from the prairies. In connection with this policy the C.P.R. four years ago bored two spiral tunnels through Mount Cathedral and Mount Ogden in the Rocky Mountain range, eliminating what was known in railway circles as the "big hill" between Field and Hector.

As traffic conditions are at present, on the westbound trip through Roger's Pass trains start the ascent of the Selkirks at Beavermouth, 28 miles west of Golden, which is at an altitude of 2,435 feet and is the most northerly station on the route. The summit of the range is 4,351 feet above sea level. Before reaching Beavermouth, the railway crosses the Columbia River to the base of the Selkirks, which, in direct contrast to the slopes of the locomotives used on the steep grades on each side of the summit.

The gorge of Bear Creek leads into a ravine between Mount Macdonald on the right and Mount Tupper on the left, entering Roger's Pass through a narrow defile.

The Pass derives its name from Major A. B. Rogers, explorer, who first penetrated the Selkirks in 1881, and discovered the narrow, rocky defile.

Passing between two serrated lines of peaks the railway proceeds to the actual summit, 4,351 feet above sea level, and thence starts the descent into the Illecillewaet Valley. The road to Glacier has a descent of 258 feet in the two miles of the summit.

The new location for the line under the Selkirks branches off from the present route near Cambie, three miles west of Glacier, and from Cambie the approaches of the tunnel run in almost a straight line to the base of Mount Macdonald, as shown in Fig. 2.

The western portal will be located about 1,700 feet below and a short distance west of Glacier House. The main passage will provide for double tracks and the approaches from both ends will also have parallel lines.

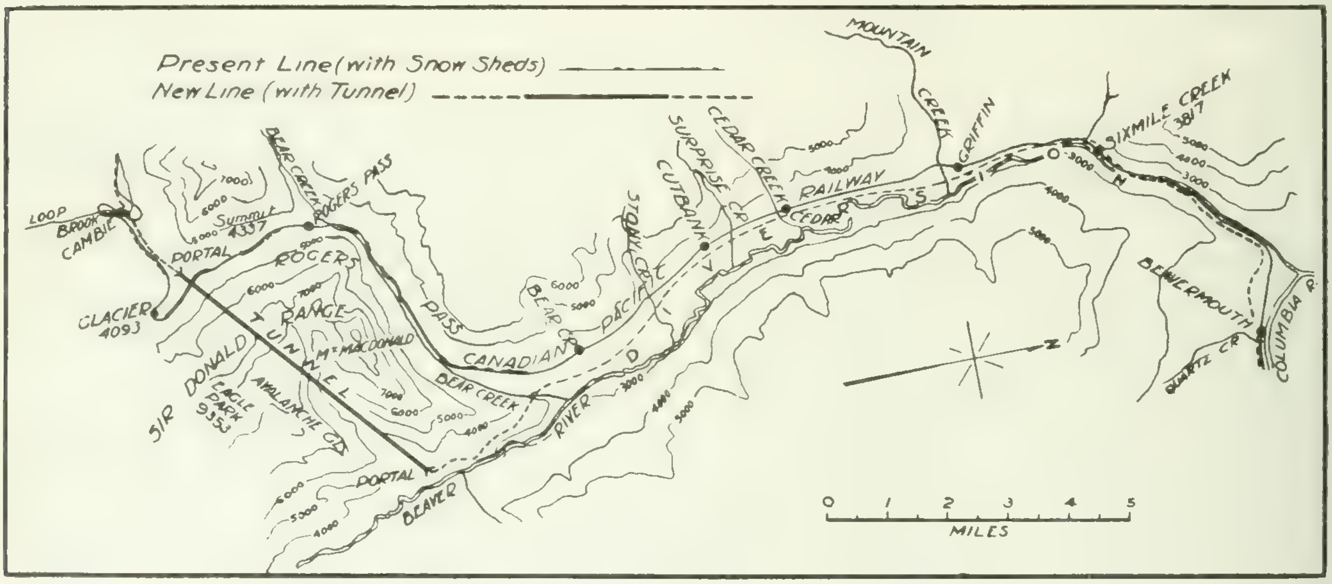

Fig. 2.—Map Showing Location of Roger's Pass Tunnel and Projected Railway Line.

Rockies, are always wooded. The line gradually climbs upward and enters the Selkirks through the gate of the Beaver River. Six Mile Creek, 5 miles west of Beavermouth, is the junction point for the new location which leaves the present route, rising at an average rate of 160 feet in the mile, and descends into the Beaver Valley, following the river to the eastern portal of the tunnel under Mount Macdonald. The scene of the operations is more than 1,000 feet below the present track level and is about 12 miles west of Six Mile Creek.

The railway parallels the course of Bear Creek after leaving the station bearing that name, following a continuous upward grade through nearly 5 miles of sheds, erected at tremendous cost to ensure the safety of trains from the slides which frequently occur. These sheds are built of stout framed timber, dovetailed and bolted together and set and reinforced with rock.

Between Bear Creek and the summit, and for a corresponding distance on the western slope of the Selkirks, men are kept constantly employed for eight months of the year keeping the lines open for traffic. Roger's Pass is the headquarters for the clearing outfits and the extra

The tunnel will follow a straight line under Mount Macdonald emerging in the Beaver Valley at a point about 1,000 feet below the present line which, as stated, reaches the summit by a gradual incline on a route notched out on the eastern slopes. The eastern entrance is situated almost immediately below Hermit, a flag station east of Roger's Pass and nearly 47 miles west of Golden.

By the route thus chosen the old line, with its long 2.2% grades, reaching a summit elevation of 4330.37 ft. in the pass, will be replaced by a new line whose summit is 540 ft. lower, effects a saving of 4½ miles in distance, and has the special advantage of eliminating a stretch of line subject to frequent troubles from snow and requiring long stretches of snowsheds. The present line has nearly five miles of snowsheds in 13 miles, while the new line will have only about 4,800 ft. The maximum grades on the new line are 2.2%, but their total length is less than one-third of those on the old line. The total curvature is also reduced considerably and two loops are eliminated. Thus while the maximum train load will remain the same, the operating conditions will be very much more favorable in consequence of the lower elevation, the shortening of the

heavy grades, and the reduction of the expense and delay due to snow. A comparison of the two lines is made in the accompanying table.

Comparison of Old and New Lines at Roger's Pass.

	Old line open summit.	New line summit tunnel.
Length, between same points..	23 miles	18 miles
Max. grades (compensated) ...	2.2%	2.2%
Length of max. grades........	22.15 miles	6.61 miles
Grade through tunnel (tangent).	....	0.98%
Summit elevation	4,330 ft.	3,791 ft.
Sharpest curves	10°	10°
Max. train load	870 tons	870 tons
Track	Single	Double

have the big undertaking finished by December 31, 1916, 3½ years from the time the work was started. Building a passage 5 miles long is a lengthy process in the ordinary way. Only a limited number of men can work in the heading at one time and delays constantly occur on account of blasting and other causes. With the pioneer bore, the work will be greatly facilitated. The side drifts leading into the course of the main tunnel will enable the drillers to attack a number of points at once. While blasting is proceeding in one part of the shaft the workers will be able to continue their activities in another instead of having to cease work each time a shot is fired, as would be the case with the one heading. The same applies to the excavation part of the work. Lines of cars loaded with material can be kept continually in motion from the various drifts.

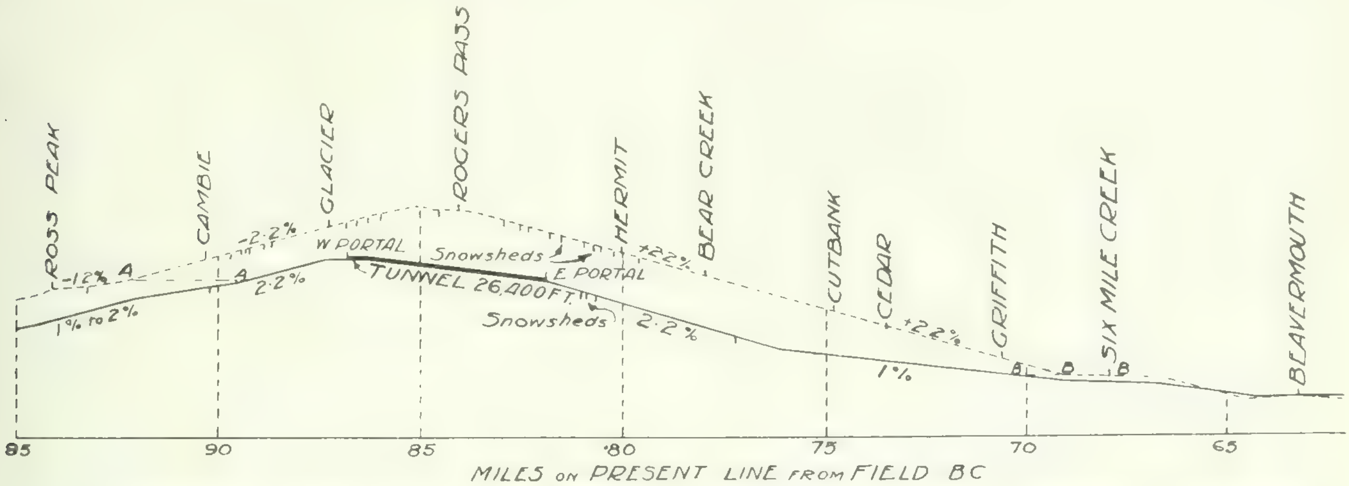

Fig. 3.—Present and Projected C.P.R. Lines Through Selkirk Mountains, Showing Location of Tunnel and Comparison of Grades.

For about 1,100 ft. at each end of the tunnel the material encountered consists of clay and boulders. The balance is expected to be in solid rock, mica schist and quartzite, so far as can be judged from the investigations made. The maximum depth of rock above the tunnel will be 5,690 ft. In cross-section, the tunnel will be 24 ft. high and 29 ft. wide, with concrete lining through the softer materials.

Method of Construction.—The contractors who have in hand the tunnel scheme are applying an entirely new method of tunnel piercing. A pioneer heading or tunnel 7 x 9 ft. in cross-section is being driven 45 ft. from the centre line of the main tunnel and with its grade 10 ft. above the subgrade of the latter. From this pioneer tunnel crosscuts will be made to the line of the main tunnel at such distances as may prove desirable, probably 750 to 1,000 ft. apart. Drifts from these crosscuts will be driven along the centre line of the main tunnel, from which drilling and shooting can be carried on while mucking will be done with air-operated shovels in the enlarged section of the main tunnel. The muck will be handled by 16-yd. side-dump cars and compressed-air locomotives. The drills and ventilating fans will also be operated by compressed air. The idea is quite in the nature of an experiment and was decided upon only after careful calculation and mature consideration. One of the principal reasons for its adoption was the fact that the C.P.R. wished to

Another great advantage is the fact that the pioneer bore will act as a ventilating shaft, enabling the passage of a current of air through two bores and the connecting passages. It will also serve a permanent purpose in the same connection on the completion of the main tunnel. This pioneer bore was started last autumn.

The work is pursued in much the same way as in the levels of a mine. Stopes are driven and holes are bored with air drills, charges set and exploded and the shattered material placed on cars and run out along

Fig. 4.—Eastern Portal of Roger's Pass Tunnel.

narrow gauge tram lines. Electric fans keep a current of air in circulation, removing the dust from the drills and clearing the atmosphere of the poisonous gases from the blasting. Gangs of drillmen will be employed in three

continuous shifts on the tunnel excavation work, which will be prosecuted from both ends at the same time. Work on the pioneer bore has been advanced at the eastern portal over 1,100 feet into the mountain, and a start has also been made on the main bore from the east end. Operations will be commenced on the preliminary shaft and the large tunnel at the western end at an early date. The excavations for the approaches at both sides are 50% completed and the wall plate heading at the east portal was started early in February. The headings will be continued, timbering carried on and bench excavated by the air-shovel until rock is encountered.

Work on the cuttings is being pressed night and day, two shifts a day being employed outside. A force of 500 men is now engaged, 300 of whom are at the western end and 200 at the eastern section. Special gangs were engaged constantly during the winter months keeping the working tracks clear of snow. Naturally, a large amount of machinery is used by the contractors, among the equipment being compressor plants for the air drills, large steam shovels, lighting plants and motors of various kinds.

Fig. 5.—Entrance to the "Pioneer" Bore.

The Roger's Pass tunnel and relating double tracking was decided upon last spring, preliminary operations being started last June. Before the work could be commenced on the excavation for the approaches, sidings had to be installed on either side of the mountains, camps established, trails and roads built and other organization details given attention. Some 50 per cent. of the excavation for the right-of-way on the western section of the work has already been done and 40 per cent. at the eastern side.

One of the engineering feats carried out in connection with the tunnel undertaking was the diversion of the course of the Illecilewaet River. The stream, which during the spring freshets assumes great dimensions, presented a serious handicap as its original channel crossed the location for the approaches at a point where a deep cutting had to be excavated to secure the necessary grade for the entrance of the tunnel, and then skirted the route for a considerable distance. While measures could have been taken effectively for carrying the tracks on trestles or bridges there would have still been a danger of the river encroaching on the line or undermining the roadbed, and so it was decided to change the course of the stream. To accomplish this purpose and to prevent future trouble, a deep trench, nearly a mile long, was dug on the left side of the approaches. This will act as a continuation of the original channel of the river and will divert the stream past the cutting to a point where an arched culvert will turn the water under the tracks again into the old creek bed on the right side of the railway.

The tunnel contract covers 8 miles of the improvement scheme which will extend to Six Mile Creek, and includes the construction of the line from the junction point at Cambie to a point about a mile on the other side of the eastern portal. A contract will be let later for the double-track connections further east.

Model villages have been established by the contractors on both sides of the mountain. The buildings are all equipped with electric light, steam heating, hot and cold running water, sanitary plumbing and other conveniences not usually found in the ordinary railway camp. Roomy dining rooms and sleeping quarters are provided for the men, the houses being connected with covered passageways raised above the level of the snow. Quarters for the clerical and engineering staffs of the contractors and the C.P.R. are provided in separate buildings. Emergency hospitals are maintained at both villages and each village has a regular police force. The executive offices of both the C.P.R. and the contractors are located at the west portal camp.

Two different kinds of weather are often experienced at the two sections of the tunnel project at the same time. At the western end the temperature may be comparatively mild while a few miles distant on the other side of the range it may be considerably below zero. More snow falls on the western slope than on the eastern side. Last winter 57 feet of snow was recorded at Glacier. This year's snow-fall has been the lightest in many years, although 37 feet was recorded.

The work is under the direction of J. G. Sullivan, Chief Engineer of the Canadian Pacific Railway (Western Lines). F. F. Busteed is engineer-in-charge, covering grade revision and double tracking as well as the tunnel. It is not without interest to observe in passing that Mr. Sullivan was first assistant engineer to Mr. John F. Stevens when the latter was chief engineer of the Panama Canal, prior to the advent of Col. Goethals. The undertaking is being carried out for the C.P.R. by Messrs. Foley Bros., Welch and Stewart, railway contractors, of Winnipeg. Mr. A. C. Dennis is the superintendent in charge for the contractors, and J. Roberts is in charge of office work. Mr. J. D. Shepperd is the railway company's tunnel engineer. Under Mr. Shepperd are two resident engineers, Mr. H. R. Phipps at the eastern end and Mr. D. Macgilp at the west. Westinghouse, Church, Kerr & Company have been retained as consulting engineers to investigate and report upon the proposed electrification of the tunnel. The relative economies of steam and water power and the effect of electric motive power on operating conditions in that region will determine the system of electric traction adopted.

TRAFFIC THROUGH THE SUEZ CANAL.

In December, 1913, 451 vessels carrying 2,100,000 metric tons of merchandise passed through the Suez Canal. Of these ships 231 were eastbound and 220 were westbound. Of the former 143 had cargoes amounting to a total of 1,055,000 metric tons as compared with 783,000 metric tons carried through the canal eastbound in December, 1912. Of the 220 vessels bound west, 150 had cargoes and carried 1,144,000 tons as compared with 1,260,000 tons during December, 1912. Of the total number of vessels which passed through the canal, 102 were mail steamers, and of these 50 were going to the east and 52 had destinations in the west.

MODERN ROAD WORK.

In a paper presented before the Roads Improvement Association of Leicestershire, Eng., Mr. H. P. Boulnois, vice-chairman of the association and a member of the engineering advisory committee of the Road Board, dwelt upon the subject of modern road methods. He laid the revolution which obtains in our preconceived methods of road building to the introduction in large volume of self-propelled traffic, which had thereby raised considerable public and scientific interest in a question which had lain dormant and neglected for many years. The year 1908 brought with it the public outcry against the dust nuisance, and the excessive damage caused to the water-bound carriageways of this and other countries by the new description of traffic. Road makers became naturally much exercised in their minds at the outcry, and at once set to work to ascertain how this great change in the character of the traffic was to be met.

Three International Road Congresses have been held since then, the first at Paris, the second at Brussels, and the third in London. Extraordinary interest in the proceedings was shown at all these congresses, which were attended by delegates from all parts of the civilized world. Many interesting questions were discussed, but no very definite conclusions could be arrived at—beyond generalities—the fact being that there are so many conflicting and disturbing factors which enter into the question as to what should be the form of construction of the modern road surface.

The traffic on the road is the primary factor which governs the selection of the type of construction to be employed. The amount and description of this traffic varies in almost every locality, and the problem is further complicated because this traffic is in a state of transition. We have to deal with the self-propelled traffic of varying speeds and weights, but also with the horse-drawn traffic, and a surface that may be excellent for the one may not be the best for the other.

It has been stated, with some truth, that the bicycle requires a road as smooth as a billiard table, a traction engine, or heavy motor wagon, requires a solid stone causeway, a horse requires a soft and easy foothold, and that a rapid motor car requires a straight track all to itself. In addition to this, the pedestrian requires a footpath for safety, and there should be little or no dust, a requirement which is shared by the occupiers of adjoining premises; also there should be a minimum of noise. The ratepayer, who pays for the road, naturally requires that the construction and maintenance should cost as little as possible, while all the users of the road require that it shall be amply wide, so that there shall be plenty of unobstructed room for the traffic.

How are these problems to be solved is the question that exercises the minds of the modern road engineer.

The earliest endeavors that were made to meet some of these difficulties consisted in tar-painting or tar-spraying the existing road surfaces, where the road was in good condition. The dust was no doubt greatly diminished, and the surface of the road was in great measure improved and preserved. Since then many hundreds of miles of road surfaces in this country have been thus treated, in most cases satisfactorily, and where there have been failures it has been due to want of proper precautions.

In this connection the Roads Improvement Association has issued a valuable little leaflet, entitled "Notes upon Tar Treatment of Road Surfaces," in which they point out the precautions that should be taken when dealing with the surface of roads in this manner. Shortly their recommendations are:—

(1) It is absolutely necessary that the crust and foundation of the road, taken together, should be sufficiently strong to carry the traffic.

(2) Before treatment the surface should be thoroughly cleansed from dust, caked mud and dung, in order that the tar may adhere properly, and that the surface of the road should be even and without depressions of potholes, etc., before the tar is applied.

(3) No tar should be applied unless the road is thoroughly dug to at least ½ in. below the surface, and they point out how impossible it is for tar to adhere to a wet, or even a damp, surface.

(4) Great care should be exercised in the selection of the tar; crude tar requires special care, as it may contain many detrimental compounds, and they give valuable hints as to the manner in which this may be avoided with reasonable care.

(5) The methods of tar-spraying by hand or machine are not discussed, but it is stated great care should be taken to apply only that quantity which the road will take, and at the same time amply cover the surface; from one-sixth to a quarter of a gallon of tar per square yard is suggested.

The leaflet contains many other valuable recommendations, and I advise all those who are engaged in this description of work to obtain a copy.

There can be no doubt that very excellent results have followed tar-spraying, and it has the advantage of being an exceedingly economical palliative, but it is only a palliative, and only solves the mere fringe of the problem of modern road methods. Something more is required in numberless cases where the traffic has abnormally increased, and a very large number of special methods of construction have been introduced during the last five or six years.

It would be impossible in a short paper to give a list of these various methods; suffice it to say that mainly all of them are on the lines of the introduction of a bituminous material to bind the stones together which form the road, instead of the now old-fashioned method of binding them with sand, dirt and water.

It has been found that the traffic not only wears the surface or crust of the road, but produces a movement among the stones themselves at some depth below the surface, causing a rocking action of the stones and producing an inter-attrition or rubbing which gradually wears off the angles of the stones until they are of a rounded shape and have no interlocking or power to resist movement among themselves. This is the main cause of the excessive mud on an ordinary water-bound road, and it is also the chief cause of the destruction of roads.

It was to meet this interstitial wear, and to confine it, so far as possible, to the upper surface, that the bituminous-bound road has been introduced. The various methods that have been adopted may be divided into the following groups:—

The ordinary water-bound macadam road with surface tarring, or painting, already referred to, and the introduction of various patented preparations to take the place of ordinary tar for this purpose.

Tar-macadam, which consists of broken stones of various sizes, thoroughly dried, then coated with tar or other bituminous mixture (either by machinery or by hand), and then laid in the road and rolled into place.

Tar slag, where slag from blast furnaces is used instead of stone, the tar being applied when the slag is at great heat, thus ensuring penetration.

Tar grouting, where the tar or bituminous mixture is poured on to and into freshly laid dry macadam after it has been laid and rolled.

A modification of the above where special standardized pitch or bituminous mixture is used instead of tar.

A further modification of the above where a layer of very fine "tar concrete" is laid, and dry macadam is spread on the top and rolled into the tar concrete.

A still later development is that of the formation of a "carpet" or covering laid on a foundation or "strength crust" so that the surface or "wearing crust" somewhat resembles a compressed asphalt carriageway.

Each one of the above types of road construction has its merits and supporters; it is difficult, however, to say which of them, if any, will be the ideal road of the future. It is, of course, necessary to bear in mind that first cost of construction, and the life of the road, have an important bearing on the question of what type to adopt, and local considerations must in great measure decide; but so far as our present knowledge on the subject goes, it has become an established fact that the ordinary water-bound road is a thing of the past, and should only be employed where the traffic is light, both in the weights carried and in quantity, or where some special circumstances require that this method of construction should still be adopted. Otherwise modern road methods are undoubtedly in the direction of bituminous roads in some form or other.

The points to be aimed at in modern road construction may be summarized as follows:—

(1) The carriageway should be built on a foundation or "strength crust" of sufficient strength to carry the weight of the traffic and to distribute the pressure of the wheels over the subsoil as to avoid any depressions or subsidences.

(2) Upon this "strength crust" there should be a wearing surface, or crust, so constructed as to minimize the abrasive action of the traffic, and also be quite impervious to water. It is universally agreed that water is even a greater enemy to a road than traffic.

(3) It has been discovered that the traffic not only wears the surface, or crust, of the roads, but also produces a movement among the stones themselves at some depth below the surface, causing a rocking action of these stones, and producing what is known as interattrition or rubbing which gradually wears off the sharp angles of the stones until they are rounded in shape, and thus have no interlocking or power to resist movement among themselves. This is the chief cause of the excessive mud on an ordinary water-bound road, and is also responsible for the ultimate destruction of the road. It has been found that the bituminous mixtures now employed in all modern road making meet this difficulty, and tend to prevent this interstitial wear of the stones by interposing a resilient substance between the stones.

(4) In addition to this, the modern road, constructed with this bituminous binder, gives a slight elasticity or resilient action in the road, and this slight elasticity is very helpful to the present form of traffic. The elasticity of the modern wheel has played a very important part in helping forward the introduction and development of mechanical transport, and a similar elasticity in the surface of the road is equally necessary to preserve the road against the destructive forces of the traffic. It is also eminently desirable that the vehicle using the road should not be subjected to the violent reaction of an improperly constructed road surface. Such reactions must, of course, be detrimental both to the vehicle and to the road. The surface of the modern road should be smooth, and at the same time have a sufficient roughness or "grip" to prevent its being slippery. With care and a selection of the proper method any excessive slipperiness can be eliminated, though so long as horses still use the roads there may be some difficulty in altogether eliminating this objection.

(6) Under modern methods the excessive camber or crossfall of the surface of roads can be greatly reduced. Excessive camber is now altogether unnecessary, and should be avoided, as it tends always to divert the whole of the traffic on to the crown or centre of the road. The camber is only required to throw the water into the channels as speedily as possible, and the smoother the surface the less fall is required to effect this object.

The requisites of a modern road may be summed up as follows:—

It should be sufficiently wide to meet the traffic requirements, but must not be extravagantly costly in its first construction.

The foundation must be sufficiently strong to bear the weight of the traffic, and the surface must be durable, and require the least possible amount of repairs at the least cost.

The road should be safe, firm, hard and at the same time resilient, with an even surface, and yet give sufficient foothold for horses.

It should be as noiseless as possible, and should be incapable of manufacturing any dust or mud. The surface should be so constructed that water cannot penetrate; that cleansing is reduced to a minimum; and that the camber or crossfall should be as flat as possible, compatible with the speedy draining off of the water falling on the surface. There should be no possibility of interstitial movement among the stones of which the road is constructed.

Coal production of South Africa in 1913 was:—Transvaal, 5,225,036 tons; Natal, 2,898,726; Orange Free State, 609,973; Cape Colony, 67,481; total, 8,801,216 tons, an increase of 684,138 tons over the previous year.

If all the capitalization of the various coal mines were added together, including the different C.P.R. mines, the total amount invested would reach the $150,000,000 mark. The annual report of the coal mines branch of the Department of Public Works for the province of Alberta shows that 39 out of the 289 companies operating in the province have a capitalization of $107,450,000. The largest capitalized company in the industry is the Canadian Coal and Coke Company, Limited, which owns four mines—Western Colliery, Beaver Mines; Lethbridge Colliery, Coalhurst; Pacific Pass Colliery, Bickerdike, and St. Albert Colliery, St. Albert. Each of these mines is capitalized at $15,000,000, 4 millions of preferred stock and 11 millions of ordinary stock—the company therefore having a total capitalization of $60,000,000.

A recent statement of the minister of the interior at Ottawa, published in the Canada Gazette, reports that British capital is interested in a petroleum prospect on the Athabasca River, 100 miles north of Edmonton. The statement is to the effect that representations have been made to the minister that certain of the applicants for leases have been negotiating with an influential British company of recognized financial standing for the development of the areas for which they have applied; that final arrangements have not yet been completed, but that there is every prospect of this company being induced to venture a very large sum necessary to thoroughly prospect the district. It is stated that the amount the company is willing to venture is in the neighborhood of $2,000,000.

MUNICIPAL ENGINEERING IN CANADA.

THE young graduate in engineering will find useful the following extracts from a paper presented to the University of Manitoba Engineering Society by Mr. L. M. Jones, City Engineer of Port Arthur, Ont. From a perusal of his observations many suggestions and much enlightenment for the man entering into engineering work may be obtained.

The field of municipal engineering in Canada is broadening more and more every year, due to the rapid growth of the population of our Dominion, the making and revising of our laws relating to sanitary and health matters, and the demands made by the public for up-to-date and modern conveniences which are necessary in making our villages,* towns and cities more attractive places to live in than they have been during the past. Think how many villages have grown into towns and towns into cities during the past decade. The writer ventures to say that traces of the municipal engineer can be found in every one of them, to a greater or less extent. This is only a beginning of what we expect, and the works already constructed are only the commencement of what will be necessary to provide for the future of these towns and cities, and the further constructing and planning of works is practically endless, and must proceed in the same ratio as the growth and expansion, subject, of course, to financial conditions.

To the mind of the writer the field of the municipal engineer is one full of interesting work and study, and probably offers more scope for the development of ability than any other branch of engineering, for the term municipal engineering covers the design of waterworks, sewers, sewage disposal, incinerators, roadways and pavements, street railway, bridges, etc., the supervision and organization required in the maintenance of these works, the collection of garbage, street cleaning, and the works connected with various other public utilities that necessarily form part of the civic organizations which are operated for the welfare of the public. Here, also, one has to do with accounting, cost analysis, municipal and commercial law, assessments, financial matters, and opportunities are afforded, through contact with the public, for studying human nature; for, after all, a good measure of the success of the town or city engineer, in dealing with the public, depends largely upon his knowledge of human nature, and especially is this the case in the smaller places. It is said, and truly enough, that the life of an engineer in charge of the engineering work of a municipality, town or city, is full of trouble and worry. The many causes for these troubles are too numerous to mention here, and while they may appear to come fast and furious, and may appear insurmountable, always bear in mind that your companion of college days, who started out on another branch of engineering, is, no doubt, having his troubles and worries, too. Let me say right here, that no matter who the man is, or whatever occupation he is following, if he is ambitious and has aspirations of some day reaching the topmost rung of the ladder in his chosen profession, his troubles and worries will be commensurate to the amount of work he is properly controlling.

The graduate who has decided to enter municipal engineering life may do so probably as an instrumentman, inspector, or perhaps be more fortunate in securing a position as assistant engineer in some town or city; and it is then that the opportunities for gathering knowledge must be seized upon if success will attend his efforts in the future. Because the college halls have been left is no reason why studies should be abandoned; rather should it be the reason for continuing along the lines where knowledge is required to more intelligently and scientifically carry along the work in hand. During the occupancy of such a position, a full working knowledge, as far as possible, of every department coming under the control of the superior officer should be secured. Ascertain in a general way the methods and organization of other departments coming under the authority of the civic administration. Study municipal law, commercial law, the laws pertaining to contracts, assessments covering the cost of work done as local improvements, the methods of calculating sinking funds, and so on. Keep abreast of the times in town and city planning, sewage disposal and treatment, purification of water supplies, and all other matters which, one might say, may be in a transitory stage. This, of course, can be best done by securing the latest books upon the subject, and finding out what the "other fellow" is doing, through the engineering periodicals. Another thing, and one which will be of great benefit in the future: learn, to a certain extent at least, to speak in public. One of the chief requisites of the municipal engineer is to be able to stand up before his council, which may be surrounded by a gathering of ratepayers, and explain in convincing terms and without losing control, his reasons for doing this thing and that in a certain way. In dealing with the public, cultivate the habit of being master of yourself at all times.

Gradually time moves on, and the graduate of a few years ago has reached the point where he feels capable of taking care of the responsibilities of a position as engineer to a municipal corporation. He receives an appointment, and then it is that he has his first opportunity of taking in hand the whole of the affairs of a civic department. The knowledge previously obtained will be a great benefit and will, no doubt, establish confidence, when properly imparted to others. Besides being engineer, he will become, in a sense, a civic administrator, as the position demands more than engineering alone. Sub-departments have to be established, systems worked out and established, and a hundred and one other things that come and go to make up the duties of the office. In the planning of civic works, don't fail to look far ahead, and plan according to what the probable development will demand in the future. Study out the problems thoroughly, and after a decision is arrived at, make sure the decision is right, stay by it, and see it through. In writing your reports on these decisions, do so as plainly as possible, for remember, you are reporting to laymen, and the simpler and plainer the report the more readily will the contents be grasped. The preparation of these reports may have been long and tedious, causing a vast amount of work. In presenting it to your council it may be turned down. Be not discouraged in this, but bring it up again. Doubtless, your work will be criticized more than that of other public officials, but remember again, that you are the head of the spending department, your department and its work is always in the limelight of civic affairs, and for these reasons criticisms of the engineering work will flow more freely. In this office, opportunities are afforded to meet men of other cities, who are continually negotiating with regard to civic affairs. These men, being of great business ability and broad vision, enable the engineer to establish another viewpoint, and mix the knowledge of business with his knowledge of engineering, and in so doing he is more able to decide wisely upon matters referred to him by his council concerning affairs of the civic administration.

RATING CURRENT METERS.*

By H. O. Brown, B.A.Sc.,
District Hydrographer, Irrigation Office, Department of the Interior.

THE great advances during the past half century in the application of water from the natural streams for water supply, power and irrigation purposes, has led to extensive investigations being made of the flow of water in the different streams throughout the year. Especially in the United States, and of recent years in Canada, under the supervision of the governments of each country, respectively, have these investigations of stream flow been carried on. In this way complete records of the flow of the streams from day to day throughout each year are being obtained.

In Western Canada, where the work in this country was first extensively introduced, a special hydrographic surveys branch was organized under P. M. Sauder, C.E., in 1909. The work was carried on throughout the provinces of Alberta and Saskatchewan, and each year extended so that at the present time discharge measurements and observations are being made of nearly all the streams throughout the provinces.

Since stream measurements were first introduced, various methods have been employed to obtain the discharge or flow of the streams. The first methods were very crude and large errors were possible, but from time to time new and improved methods were introduced. The method of obtaining the stream discharge now almost universally adopted is the "velocity area" method. The area of the cross-section of the stream is obtained by the width of the cross-section being measured and soundings taken at equal intervals in the cross-section, the cross-section thus being divided into smaller sections. The mean velocity of the stream must next be obtained.

The velocity at different points across the stream may be obtained by direct or indirect methods. By the use of floats and float rods, the velocity may be obtained directly, but this method is greatly limited in its application as the necessary conditions of the stream are usually difficult to locate. The velocity of the stream is obtained indirectly by the use of current meters, where a known relation exists between the revolutions of the meter and the velocity of the water. The advantages of the current meter are easily recognized for with it the velocity at any point in the cross-section may be observed and the velocity observations are more easily and accurately obtained.

Since current meters were first introduced in the latter part of the eighteenth century many improvements have taken place. The first type of meter used was that of the float wheel, but this was soon modified to be used beneath the surface. In America patents were taken out as early as 1851. With these early types of meters great difficulty was experienced with the mechanical recording apparatus, due to the excessive friction, but with the introduction in 1860 of an electrical recorder this difficulty was eliminated. Of the many American types of meters which have been constructed, each for use under some special condition, those in most common use are the Price, Haskell and Fteley. The Dominion Irrigation Surveys use the different patterns of the Price meter exclusively, while the United States Geological Surveys have adopted the small Price meter for their work, which has had many improvements in its construction introduced by their engineers from time to time.

Methods of Rating.—Rating a current meter is the determining of the relation existing between the velocity of the moving water and the revolutions of the meter wheel. Theoretically the ratings of all meters of the same make should be the same, but, owing to slight variations in construction, the ratings differ. The accuracy of a discharge measurement depends largely on the accuracy of rating the meter used. Errors of observation are as likely to be too large as too small and are therefore compensating. Errors in a rating table always have the same sign and are cumulative and should therefore be reduced to a minimum.

The method for rating meters now universally employed is that of moving the meter through still water with a known velocity. This method is sub-divided according to whether the meter is suspended from a car or

Fig. 1.

boat, and moved in a straight line or suspended from the end of a long arm and moved in a circular path. The former is called the *linear method*, the latter the *circular method*.

In the linear method the meter is moved through still water along a straight run. A platform is placed by, or over, the water, as the case may be, carrying a track about 200 or 300 feet long, in which the car for carrying the meter is run. The track is laid near the edge of the platform and the meter is suspended in the water from an arm projecting from the side of the car. The car may either be propelled by hand or electrically. Observations of the distance, time and number of revolutions for each run are noted and from these data the revolutions per second and velocity in feet per second are afterwards computed. Many runs are made for each meter, the velocity varying from the least that will cause the meter to revolve to several feet per second. The results of these runs when plotted define the meter rating curve for the meter and from this curve the rating table is computed.

The circular method of meter rating differs from the linear method principally in that the meter is moved in a circular path instead of along a straight path, as mentioned before, the observations taken in each case being practically the same. The meter is suspended from an arm projecting from, and supported by, a vertical centre shaft. The shaft may also be revolved by hand or electrically and a counter shaft with friction pulleys is used to obtain the low velocities. The meter is usually suspended from rods, for reasons stated later, and stay lines are used to keep the meter in place. A circular rating station is dependent upon a linear station for notes by which to

*From the recent report of the Chief Hydrographer, Department of the Interior, on the Progress of Stream Measurements.

adjust the distance of the meter centre from station centre. It has been found by practical test for a small Price meter suspended by rods that the distance is 8.95 feet, for a 60-foot run, or about 0.60 foot less than a 60-foot periphery geometrically requires, which is due to the actuating and resisting forces on a circular tract.

A limited number of comparisons have been made between the circular and linear methods of rating, and it has been found that the circular method of rating cannot be relied upon for rating with the cable, owing to the swinging out of the meter, which introduces an uncertainty in the distance of the run. The ratings on the rod by the circular method agree with the ratings obtained by the other method, as the meter is held firmly in place. It has, however, been found that, owing to the vibration of the car in the linear method, the meter, when suspended on a rod, is retarded somewhat. Therefore, the results of ratings on a cable in this method are being used in preference to those on a rod, even though the meter is used on a rod. While the matter has not been fully investigated, it is believed from the data available that in actual field practice there is no difference between the suspension on a rod and on a cable. The ratings by the circular method on a rod have been found to agree with those by the linear method on a cable, which indicates that in the linear method the rod ratings are affected.

Description of Station and Apparatus.—The current meter rating station of the Department of the Interior, Irrigation Office, at Calgary, Alberta, was constructed early in the season of 1911. It was in operation during the latter part of the open season of the same year and the results obtained proved very satisfactory. At the opening of the season of 1912 the necessary attachments were placed on the car for rating with a cable and a few other improvements made in the apparatus. The station was in operation throughout the whole season until freeze-up and besides rating the meters used by the Dominion Irrigation Surveys several meters were rated for other parties. The following is a brief description of the rating station and apparatus.*

The still water is provided by a concrete tank 250 feet long by six feet wide and five and a half feet deep (inside dimensions), the depth of water in the tank being maintained at about five feet. The track laid along the side of the tank upon which the car is run is of 16-pound steel rails, laid to a gauge of 32⅜ inches on 4-in. x 6-in. ties. Great attention was paid in the laying of the track to have it laid solid and as level as possible with close rail joints (fish plates and bolts being used at every joint) in order that the car should run very smoothly. In the design of the car, which is propelled by hand, the main features have been copied from the car used by the Bureau of Standards, United States Government, at their rating station at Washington, D.C.

The axles of the car run in roller bearings and the frame supporting the front axle with bearings is attached to the platform of the car by a hinge joint. This allows the four wheels of the car to rest upon the track, though it be slightly uneven in places, and makes the level of the platform dependent upon the rear axle. It is thought that this arrangement eliminates all the sharp, vertical movements which might otherwise be transmitted to the current meter in its travel through the water. Two iron arms project from the car to the centre of the concrete tank and these hold the rods, or cable, from which the meter is suspended for rating. Iron arms also project on either side and at right angles to the lower arm for attaching a wire stay line to the meter, when being rated on a cable or small rods. The wheels of the car are solid castings and all the steel in the car is of heavy section, it being easier to maintain a uniform rate of travel with a heavy car than with a light one.

The diagram (Fig. 2) represents the electrical connections used for the recording apparatus at the rating station. As stated before, observations of the distance, time and number of revolutions for each run must be taken. The run is of a fixed distance of 200 feet (25 feet being left at each end for starting and stopping the car), therefore the number of revolutions and the time of the run only have to be observed. The time of the run is recorded automatically by an electro magnet operating a stop watch. A switch is placed at each end of the run and the car in passing over each closes the electric circuit in which the stop watch electro magnet is connected. This causes the steel core to be drawn up into the solenoid by magnetic force and a lever fastened to the end of the core pushes on the stop watch stem. At the beginning of the run the watch is thus started by the car closing the first switch and stopped at the end of the run when the other switch is closed. The double throw switch is used to throw three extra cells into the circuit by moving the blade over, as shown, when the switch at the *out* end of the run is to operate, for here the resistance of the circuit is increased. This arrangement prevents the watch from being struck too hard a blow by nine cells being in the circuit instead of six, as required for the switch being operated at the *in* end.

The revolutions of the meter for each run are also automatically recorded by an electric recorder arranged in circuit with the meter, as shown in the diagram. The circuit for recording the revolutions of the meter is ready to be closed by the contact in the meter head, when a switch on the car is thrown in, as the starting post is reached. The meter continues to record until the end of the run is reached and then the circuit is again broken by a switch on the car being opened as the end post is reached.

As the meter seldom records exactly at the beginning and end of each run a small error is introduced in taking the recorded revolutions as the revolutions for the time of the run. For this reason the writer adopted the following method of obtaining the data for more accurate calculations of the revolutions per second of the meter for each run.

When the car has passed the starting post, when a run is being made, as the first contact of the meter is recorded a separate stop watch is started, independent of the watch recording the time of the run. The first time the meter wheel records may be a few feet past the starting post, but the time for this unknown part of a revolution of the meter over this distance has not been recorded either. The number of revolutions of the meter after the watch has been started is observed until the meter is almost at the end of the run when the stop watch is again stopped at the end of a complete revolution of the meter as recorded. Thus the time for an exact number of revolutions of the meter and this exact number of revolutions of the meter have been observed for the run, and from these data it is seen that the revolutions per second are more accurately calculated. In this way the error pointed out above was greatly eliminated and better defined rating curves were obtained.

Rating Meters.—The method of suspension employed in the rating of the meter depends upon the type of meter.

*For a full description of this station the reader is referred to *The Canadian Engineer* for October 24, 1912.

For the reasons mentioned before, all the meters that can be suspended from a cable are rated thus, but the meters designed for use on rods only necessarily have to be rated upon the rods. When the meter is suspended by a cable, it is fastened to the upper part of a hanger to which the cable is attached and the meter in this position is free to tilt up or down. The lead weight (for large meters, 15 pounds, and for small meters, 13 pounds) to keep the meter in position in the water is fastened below the meter upon the hanger. The stay line is fastened to the top of the hanger and to the end of the arm on the car for this purpose and facing the direction in which the run is to be made. The suspension cable used is an electric cable which is about a quarter inch thick. This cable avoids the use of an extra cable for the electric circuit and is also used upon the meters in the field. It is passed through the loop in the lower arm projecting from the car and fastened to a swivel on the upper arm. The length of the suspension cable is just sufficient to allow the meter to hang about two feet below the surface of the water and by means of the swivel the meter is easily faced in the proper direction. Care must be taken to see that the meter rests horizontally and parallel to the direction of the run and that the electric wires connected to the meter will not cause the meter to alter its position when in motion or interfere with the meter wheel.

some distance back from the starting point, that the meter wheel may reach the corresponding revolutions per second. After the first run has been obtained the velocities for the following runs are increased by a half foot per second, respectively, as nearly as possible, so as to give points for the rating curve which will be uniformly distributed.

For each run, as stated before, the time is automatically recorded and the length of the run being 200 feet, the velocity in feet per second is computed from these data. Also, the time of a certain number of revolutions of the meter wheel having been observed for each run, the corresponding revolutions per second are computed and these results being plotted with revolutions per second and velocity in feet per second as co-ordinates locate the points which define the rating curve.

The rating curves are plotted on cross-section paper, the scales used being: five centimetres equal to 0.5 revolutions per second on the "Y" axis for high and low velocities and five centimetres equal to 1.0 foot per second on the "X" axis for high velocities, with five centimetres equal to 0.5 foot per second for the low velocity curve. When two curves are drawn separately for the high and low velocities, respectively, the rating curve usually consists of two straight lines, the break occurring very close to a velocity of 2.00 feet per second. Theoretically there is no pronounced break in the rating curve at this point, but, owing to the fact that the curvature is so decidedly small both above and below this point, it was decided to draw the curve as two straight lines. When plotting the curve the high velocity curve is usually drawn first and the point of revolutions per second corresponding to the velocity of 2.00 feet per second is transferred to the low velocity scale and the low velocity curve drawn from this point downward.

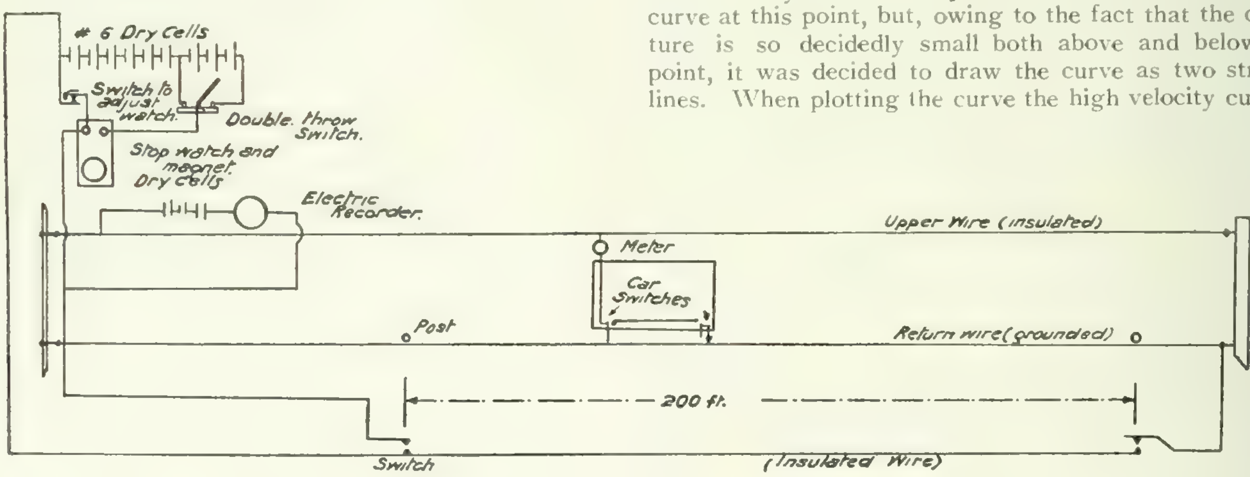

Fig. 2.

When the meter is suspended from rods, it is, as mentioned before, placed about two feet below the water surface. The rods are firmly held in the arms projecting from the car and very light waterproof electric cable is fastened to the meter for the electric recording circuit. A stay line is also fastened to the meter, when the rods used are light enough to bend when the high velocity runs are being made.

The meters are usually rated first in the condition in which they have been sent in from the field and then, if necessary, are thoroughly cleaned, fitted with a new bearing, properly adjusted and oiled and rated again. In all cases it is necessary to see that the commutator in the meter head is adjusted to give a good contact to properly operate the electric recorder, which will not operate with as small an electric current as the telephone recorder used in the field.

In rating the meter several runs are made, usually about twenty, with velocities varying from the least that will cause the meter to revolve to about ten feet per second. It is very essential that the velocity for each run be uniform throughout and that this velocity be attained

On each separate rating curve sheet for each meter, besides the rating curves for that meter, is placed the standard rating curve for that type of meter. This curve is used as a comparison for the other rating curves of the meter, and these rating curves, being placed together on the same sheet, the general behavior of the meter from rating to rating may be observed.

Construction of the Rating Tables.—If the rating of a meter comes within one or two per cent. of the "standard" curve for this type of meter then the standard table is accepted for this meter. If the rating shows a greater difference than this then an individual table is constructed from the rating curve.

Two general forms of rating table are in use: one which gives the velocity to the nearest 0.01 foot per second corresponding to each 0.01 revolution per second from 0.0 to that corresponding to the highest velocity, for which the meter shall be used; and another form which

gives the velocity to the nearest 0.01 foot per second corresponding to a certain number of revolutions in a certain number of seconds. The number of revolutions for this latter form of rating table is 5, 10, 20, 30, etc., and the time period being 30 to 60 seconds or 40 to 70 seconds. During the past season both these general forms were made out for each meter by the Department of the Interior, but it is intended to adopt the Revolution-Time form. The 40 to 70-second form of the Revolution-Time table has been used because of the lower velocities given and also the time of an observation being necessarily increased, but it also has the slight disadvantage that the velocities do not increase continuously between the 5, 10 and 20-revolution columns as in the 30 to 60-second table.

The Revolutions per Second-Velocity per Second table is constructed from the rating curve by reading the V.P.S. corresponding to each .05 R.P.S. and then filling in velocities corresponding to each .01 R.P.S. by dividing the differences evenly. The rating table of the second form gives the equivalent R.P.S. for the number of revolutions for each second of time between 40 and 70, so in constructing the table of this form, observations are taken from the curve of the velocities corresponding to each five seconds of time throughout the table. The differences in this form cannot be divided evenly between these points because the R.P.S. do not increase uniformly, so the differences must be divided proportionally to the increase of R.P.S. When the table of the first form is constructed first, the greater part of the table of the second form can be filled in from it and thus reduce the number of calculations.

One disadvantage given by engineers for the table of the second form is that it is necessary to interpolate to obtain the velocity, when the time of the observation is observed to the fifth of a second. For the low revolution columns it is not necessary to interpolate if the time is observed to the nearest half second, as the velocity increase is small, but in the columns from twenty revolutions upwards the velocity differences increase rapidly. The time being observed to the fifth of a second it seems, to the writer, that tables made out for each fifth second would be very helpful. These could be constructed by the engineer from the present form of rating table for velocities between the limits in his work.

It has been decided that the 1914 Forestry Convention is to be held in Halifax, and the date definitely decided upon is from September 2 to 4, 1914.

According to the Rheinasch-Westfalische Zeitung, of Essen (Ruhr), a new process for ridding boilers of troublesome scale has been adopted, which promises to become of universal use, it being to date the only practicable process for this sort of work. The method consists of passing an oxy-acetylene flame over the scale, which will be removed in large sections, with the wall of the boiler remaining cool during the operation.

The Shipshaw Water Power Co., which is being developed by Price Brothers and Co., is located on the Shipshaw River, at Murdoch Falls, about two miles from Kenogami. The present installation of the company consists of two 3,000 h.p. units. It is intended to develop at first about 5,000 h.p., which amount has been contracted for by Price Brothers and Co., at $15 per h.p. This will give gross earnings of $75,000.

A report has been published at Berlin, Germany, to the effect that the Schleswig-Holstein Government has ordered that steps be taken preliminary to the construction of a canal between Eckernforde and the Kaiser Wilhelm Canal, of a canal between the broad part of the Schlei and Eckernforde, and of a harbor at Eckernforde. This indicates the probable consummation of a long-considered plan for a second outlet from the Kaiser Wilhelm Canal to the Baltic, which would be chiefly of military value.

A SHORT METHOD OF THE STADIA.

By John H. Curzon.

FOR a great many purposes the common method of stadia surveying is too laborious and not quick in either the field or office. Especially is this true in the case of a rough topographical survey which takes almost as much time as a more accurate one would require, while the time expended in figuring and plotting the survey is greater than the time required for the actual field work. The method herein described is quite accurate enough for landscape engineering and may be used to good advantage in a great many ways, for which heretofore the usual practice has been considered too arduous for the result to be obtained. The author has used this method to very good advantage in rough prairie work in the West and has found that when one becomes practised it can be made a great time saver.

For the horizontal angles the same method as for the regular stadia is employed, viz., both A and B verniers are read and noted.

No record is kept of the vertical angles. The elevations are found by "rod intervals." Suppose the instrument to be set up at a point A and values are known of the height of the instrument (H.I.) above the point and also of the elevation of the instrument above datum (E.I.). This is generally assumed, e.g., E.I. is 129.67 and H.I. is 5.32, whence the elevation of the station is found to be 129.67 — 5.32 = 124.35.

Then, suppose the instrument is sighted on some point, B, with the telescope clamped level and read 4.28 with middle wire and 3.00 and 5.56 with lower and upper wires respectively. Then the elevation of point, B, would be, as in direct levelling, 129.67 — 4.28 = 125.39, and the distance approximately 5.56 — 3.00 = 256 ft.

No account is taken of "f + c" as in ordinary topographical surveying. Distances to intermediate points are close enough to be read directly off the rod.

Now, suppose the rodman moves on the same radial line to a point C, which is above the middle wire of the telescope when clamped level. The method of procedure is then as follows: With the instrument clamped level take a sight on some point which is in line with the upper cross-hair such as a bush or stone (or point on the rod) which is easily visible. Without taking the eye away from the telescope use the slow-motion screw to raise the telescope until the lower cross-hair cuts the bush or point just where the upper cross-hair cut before. If you do not yet hit the rod with the middle hair, proceed as before and turn the telescope through another interval, sighting the top hair on a bush or other object as before. Now the middle wire reads 6.84, the upper wire reads 10.06 and the lower wire reads 3.62. Then the rod interval is 10.06 — 3.62 = 6.44 and the distance is approximately 644 ft.

As for the elevation, the E.I. is 129.67 and the telescope has been through three "rod intervals" of 6.44 and read 6.84, therefore the elevation of point C is 129.67 + (3 × 6.44) — 6.84 = 142.15.

If the instrument has now to be moved up to point C, after setting, measure the H.I. and find the E.I. For example, 142.15 + 5.02 = 147.17 is the new E.I., when set up at point C. Make the B vernier read the same as the A vernier read when sighting on C from A. To check the difference in elevation of points A and C, level the telescope, sight with low wire on some point in the distance and depress the telescope until the upper wire

strikes the point sighted on previously by the lower wire. Then proceed until the rod is hit with the middle wire. Supposing it has been a drop through two intervals and the reading is 8.80 with the middle wire, and 12.13 and 5.47 respectively with the upper and lower wires. Then the interval is 6.46 and the distance, 646 ft. Previously the distance was found to be 644 ft.; therefore, average is 645 ft., which is the corrected distance. The elevation of point is now found to be $147.17 - (2 \times 6.46 + 8.80) = 124.45$, whereas it was previously 124.35. Therefore the mean elevation is 124.40 and the corrected Elevation of Instrument is $147.17 - .05 = 147.12$.

When the E.I. is corrected in this manner it is customary to distinguish it in the notebook by drawing a circle around the figures. The headings for the form of notes in the field book are as follows:

Sta.	A	B	Dist.	Rod	Elev.	E.I.

The right-hand page is reserved for sketching and remarks.

The author is fully aware that many errors are introduced by this method but offers no apologies for it whatever for its use in rough survey work.

IMPROVEMENT OF MONTREAL HARBOR.

THE Harbor Commissioners of Montreal have commenced preliminary operations in connection with the harbor improvement to be carried out this season, and in a short time the full program of work, involving an expenditure of approximately $3,000,000, will be under way. It will be a continuation of the improvements already begun, and will include the completion of the 20-foot channel to divert part of the St. Mary's current.

The electrification of the high-level railway will be commenced and the railway itself may be extended, including the construction of several bridges, for a distance of about 4 miles to Pointe aux Trembles, where the construction of the new wharf for the Canada Cement Company will shortly be commenced.

At the site of the dry dock dredging will be continued and the quay walls raised for approximately 800 ft. of length.

It is probable that the new wharf for the Armstrong-Whitworth Company at Longueuil will be constructed this year, while on the Montreal side of the river, work will be carried on in connection with the new Victoria pier, which is already about half completed.

Dredging is to be continued throughout the harbor and ship channel, the dredging of the latter to be carried on by the Government, it being outside the jurisdiction of the Harbor Commission. It is understood, however, that the Commissioner's dredges will assist on this work.

The 20-foot channel mentioned above in connection with St. Mary's current, the dredging of which will constitute one of the most important of the harbor works this year, has for its object increase of the flow of water outside the islands, thus diminishing the current in the harbor and making it more suitable for shipping. Last season the channel was completed for a short distance from the south end and a noticeable improvement was the result. This year dredging will progress from both ends of the channel, and it is expected that the work will be completed before fall.

CONSOLIDATION OF ENGINEERING SOCIETIES.

AT the annual meeting of the American Institute of Electrical Engineers a paper was read and discussion took place on the subject of combining the membership, or parts thereof, of the national engineering societies of the United States in one association. The primary object might be sufficiently and plainly described as "to foster and develop the human factor in the engineering profession, to place the engineer on the same plane as the lawyer and doctor," "for the discussion on engineering in general . . . except scientific and technical subjects . . ."

There was no adverse discussion and both paper and discussion show that even the leading members of the great national societies whose objects are to advance science and engineering realize that something more is needed. What they realize may be stated in this way:

(1) An organization separate from those of a scientific character is essential to develop the standing of the engineer as a social unit.

(2) There is no "adjectival" distinction between engineers when their interests in society are to be protected or advanced. At such a time architectural, civil, electrical, mechanical and mining men stand as a unit.

It will probably take much time to develop a scheme which will appeal to the members of four or five different bodies so large in numbers and pregnant with tradition as these national engineering societies, but in the meantime it cannot fail to be of interest to the profession at large to know that younger bodies are leaving the slow and heavy methods of debates to their elders.

An important consolidation of societies has just been effected by an order of the Supreme Court of the State of New York which has merged the Technical League of Engineers and the American Society of Engineer Draftsmen, both incorporated bodies, into a new organization to be known as the Technical League of America. The name was adopted because it includes architecture and every branch of engineering as well as every grade of worker in all those branches from engineer-in-chief to tracer or technical student.

These two societies, though comparatively young, have done good work; the Technical League of Engineers among civil service departments, and the American Society of Engineer Draftsmen in commercial fields.

This consolidation is the result of a thorough and comprehensive study of every phase of the question of placing the engineering profession on a higher social plane and obtaining for the engineer and his assistants that recognition, both economic and social, which is due to men through whose untiring efforts almost every possible safeguard for human health and every device for the higher development of the human race is conceived.

The experiences of the two organizations were analyzed; the tenor of opinions expressed in the technical press were studied and weighed together with papers, discussions and addresses made before other engineering societies. Committees of these two progressive bodies came together and after careful consideration of all of the facts endorsed the following significant pronouncement: In advancing the economic and social status of the engineer, no discrimination can be exercised:

Against any branch of architecture or engineering or any subdivision thereof.

Against any grade of engineer or assistant which the necessities of the profession has brought or may bring into existence.

On account of geographical location.

WATERPROOFING OF MASONRY AND BRIDGE FLOORS.

THE following is the final report of the committee, on waterproofing materials and methods of the American Railway Engineering Association, with respect to the waterproofing of masonry and bridge floors. This report, presented at the recent convention in Chicago, is regarded as a very satisfactory and valuable summary of established practices. From it the following notes are taken:—

Structures should be waterproof when it is necessary: (1) To prevent dampness in walls above grade, and in walls and floors below grade. (2) To prevent flooding of basements and pits, which are at all times or occasionally below the ground water level. (3) To prevent percolation or leakage of water through the masonry and the formation of unsightly deposits on exposed surfaces. (4) To prevent the dripping of water through a bridge floor over a street, and in the cases of solid floors of steel or reinforced concrete bridges, to protect the steel from corrosion. (5) To prevent the entrance of water into tunnels, either above or below ground water level, or subaqueous tunnels. (6) To prevent leakage from reservoirs. (7) To prevent the penetration of water into the masonry.

The following outline includes the ordinary methods of waterproofing:—

(I.) Coatings: (1)Linseed oil paints and varnishes. (2) Bituminous: Asphalt coal tar. (3) Liquid hydrocarbons. (4) Miscellaneous compounds. (5) Cement mortar.

(II.) Membranes: Felts and burlaps in combination with various cementing compounds.

(III.) Integrals: (1) Inert fillers. (2) Active fillers.

(IV.) Watertight concrete construction.

Walls above grade are waterproofed by coating with paints, varnishes, or waterproofing washes, or by plastering with cement mortar. The coating or plaster may be applied either on the inside or outside of the wall.

The walls of basements and pits are waterproofed, either by the application of coatings, membranes, integral or watertight concrete construction. Membranes are usually protected with concrete, brick or bituminous binder.

Where basement or pit walls and floors are below the ground water level, they must be so designed as to resist the existing hydrostatic head in order to prevent cracks and leakage. Such walls may be waterproofed by the integral method or by watertight concrete construction. When exterior waterproofing is employed, the membrane method is generally used properly protected.

Stone, brick or concrete arches, retaining walls, abutments, subway walls and culverts are waterproofed by any of the methods mentioned in the preceding paragraph. For important structures, the membrane method is most generally used.

When surface coatings, integral waterproofing or watertight construction is used, particular attention must be paid to reinforce the work against cracks due to expansion, contraction or settlement. The expansion joints must be waterproofed by sheet copper or lead built into the adjoining sections.

The solid floors of steel and reinforced concrete bridges probably present the most difficult problems of waterproofing. In steel troughs or I-beam floors a concrete filling may be used to bring the deck up level with, or above the top of the steel in the floor. The floors of this class of structure are usually waterproofed by the membrane method.

Tunnels in which the ground water level is below the invert may be waterproofed by any of the aforementioned methods.

Subaqueous tunnels present a different and distinct problem of waterproofing; usually reinforced concrete, or plain concrete, with iron or steel lining is used. The structures are designed to resist the hydrostatic head.

The walls and floors of reservoirs may be waterproofed by any of the four methods before mentioned.

Coatings.—Linseed Oil Paints and Varnishes.—Linseed oil paints and all coatings containing linseed oil are reactive to atmospheric conditions and to alkaline water. Applied as a damp-proofing to the surface of a concrete wall which may be permeable to moisture, the paint is likely to be of short life unless the surface is specially prepared. To secure the best results, the wall must be dry and clean before application. The paint is applied with a brush in the ordinary manner. The coating power of paint is approximately 200 sq. ft. of wall per gallon of paint, but varies with the thickness of the paint and the nature of the surface. The prices of the paints sold for damp-proofing masonry and concrete surfaces carry from about $1 to $3 per gallon for the material.

Bituminous Coatings.—This class includes asphalt, petroleum residiuum, coal tar and coal tar pitch. As used for waterproofing purposes, they are solid at ordinary temperatures, and are, therefore, often applied while hot. As they are soluble in benzine and coal tar naphtha, they are frequently mixed with these solvents and applied in a liquid form. Two coats cost about 1 ct. for material and ¼ ct. for labor per square foot.

Asphalt.—Waterproofing by the application of liquefied asphalt, as a paint applied with a brush or mop, has been used on practically all kinds of engineering structures as a surface coating.

Bituminous coatings applied cold by dissolving in naphtha, instead of hot, do not set instantly, therefore are much easier to apply. The work can be done by an ordinary laborer, care rather than skill being required in its handling. All walls that are to be waterproofed must first be allowed to dry.

If the waterproofing is made by dissolving the bitumens in a volatile solvent with a dryer so that it may be applied cold like a paint, it is difficult, if not impossible, to prepare a paint that will dry to the right consistency and then stop. The usual result is that the drying and hardening continues until it reaches a point where its waterproofing qualities are destroyed.

Hot asphalt will not adhere to cold, damp concrete. Several different methods of heating the surface of the concrete have been used. Gasoline has been poured over the surface and burned; hot sand has been spread over the surface and swept back as the waterproofing proceeds. It is claimed, however, that heating the surface draws up moisture and prevents the asphalt from adhering. It is necessary that the concrete be thoroughly dry before the asphalt mixture is laid upon it, as the steam caused by placing the hot material upon a damp foundation will prevent adhesion. Good results have been obtained by first painting the surface to be treated with a priming coat of asphalt cut with naphtha or benzine and then applying the hot asphalt over this coat.

In applying hot asphalt directly to steel, difficulty is found in getting the asphalt to adhere to the steel, and no dependence can be placed upon adhesion to vertical surfaces.

The asphalt should be heated in a suitable kettle to a temperature not exceeding that allowed in the specifications for any particular structure depending upon the

material used. If this temperature is exceeded, it may result in pitching the asphalt. Before the pitching point is reached, the vapor from the kettle is of a bluish tinge, which changes to a yellowish tinge after the danger point is exceeded. The asphalt has been cooked sufficiently when a piece of wood can be put in and withdrawn without the asphalt clinging to it. Care should always be taken not to prolong the heat to such an extent as to pitch the asphalt. Should it become necessary to hold the heated asphalt for any length of time, the fire should be drawn or banked and a quantity of fresh asphalt should be introduced into the kettle to reduce the temperature. Excessive heat converts the petroline or cementitious constituents of the asphalt into asphaltene, which is devoid of cementing properties, and by so much reduces the cementing quality—the vital element—of the asphalt. The fire should not be allowed to come into direct contact with the melting kettle or tank. Asphalt coatings cost about 65 cts. per gallon for material and 3/10 ct. for labor per square foot, a gallon covering about 100 sq. ft. per coat.

Asphalt Mastic.—Various results have been obtained by the use of asphalt mastic, and it is probable that much is dependent upon the quality of the mastic. The requirements of a sand for asphalt mastic are much the same as those for cement mortar. It is common practice to mix a certain amount of limestone screenings with the sand, with the intention of securing an aggregate with the least percentage of voids. The strength and compactness of the mastic will depend considerably upon the percentage of voids, and the proportion of asphalt used in the mastic should be sufficient to fill the voids and completely coat each particle of sand and screenings. Too much asphalt will produce a mastic that is soft and easily indented, does not offer a good protection against the ballast on a bridge floor, and flows more readily than a well-proportioned mixture.

The asphalt and sand are separately heated to from 325 to 350°. The proper proportions are measured out simultaneously, poured into a mixing vessel and thoroughly mixed. The operation of mixing the asphalt mastic requires care in heating the ingredients to secure uniform temperature, not to overheat the asphalt, to proportion the mixture accurately, and to mix the materials thoroughly. The mixture is dumped in place and spread evenly over the surface with wooden floats, shovels or rakes. After being compressed with tampers, the surface is finished with hot smoothing irons.

Asphalt mastics are usually applied in layers not exceeding ⅝ in. in thickness. Usually two coats are applied, the coats to break joints not less than one foot. The cost of asphaltic mastic 1¼ in. thick is about $30 for material per net ton, a ton covering about 375 sq. ft.; the cost of labor is about 2 to 5 cts. per square foot, depending upon location and conditions.

Coal Tar and Coal Tar Pitch.—Tar produced by the distillation of bituminous coal is used in waterproofing, either applied cold as a paint by dissolving in naphtha or benzine or applied hot. It is also mixed with sand, gravel or screenings to form a mastic. It is generally found to be difficult to obtain coal tar of good quality. Good coal tar compares favorably with asphalt as a waterproofing material. The present price of coal tar pitch used for waterproofing is about $17.50 per net ton.

Coal Tar Paint.—Annapolis mixture is a coal tar paint composed of 1 part kerosene oil, 4 parts Portland cement and 16 parts refined coal tar. The mixture is put on with a paint brush in the same way as ordinary paint is applied. The compound not only covers the surface, but sinks into and bonds with it, so that two or three coats are sometimes required. It has been found to adhere to moist or even wet concrete. The cost for three coats is about ½ ct. for material and about ½ ct. for labor per square foot.

Liquid Hydrocarbons—Paraffin and Petroleum.—Waterproofing by the application of a coating of melted paraffin has been used on masonry in much the same manner as hot asphalt. Paraffin is also applied cold as a paint made by dissolving the paraffin with naphtha. Petroleum oil is sometimes applied to the surface of masonry as waterproofing. The efficiency of these materials depends upon their absorption into the surface of the masonry. Applied to clean, dry surfaces of porous masonry, they are fairly efficient as damp-proofing.

Soap Washes.—Solutions of soap applied as a wash for waterproofing or damp-proofing masonry surfaces are not recommended, as no permanent waterproofing effect can be depended upon.

Soap and Alum Washes.—Waterproofing by alternate washes of soap and alum is one of the oldest methods of treating masonry surfaces, and has given fair results when properly used on surfaces sufficiently dense and impermeable to afford support for the void-filling material. Inferior materials and workmanship cannot be atoned for by the use of alum and soap washes. The alum and soap combine and form an insoluble non-absorptive compound in the pores of the masonry surface. The cost of applying two coats each of soap and alum washes is about ½ ct. per square foot of surface.

Cement Mortar.—The method of waterproofing masonry structures by the application of a plaster coat has proved efficient when the plaster has been properly applied. The surface to be waterproofed must be clean to insure bond between plaster and masonry. Old surfaces may be cleaned by chipping off a thin layer from the face or by the use of a sand blast or steam jet. The surface must then be kept wet until it has absorbed water to its full capacity. A wash of neat cement mortar should then be applied with a brush. This wash should be mixed to the consistency of cream and should never be used after it is 45 minutes old. The plaster should be applied over the cement wash before the latter has commenced to dry. The sand to be used in the mortar should receive careful attention. It should be well graded from fine to coarse, the maximum size of particles being that passing a No. 8 sieve. Portland cement and sand should be mixed in the proportion of 1:1½. The mortar should be applied in layers about ⅜ of an inch thick if more than one coat is used. Each coat should be applied before the preceding one has attained its final set. Good workmanship is essential and the use of a wooden float is necessary in order to obtain a dense, impermeable coating. As ordinarily applied, the finished coating is about ¾ of an inch thick. The cost of ¾-in. plaster, applied as above, will be about 6 cts. per square foot.

Membranes.—Membrane waterproofing consists of the formation of a mat or covering of waterproofing material over the surface to be waterproofed, made up of a number of layers of membrane united by a cementing material. Being somewhat elastic and independent of the movement of the surface, this method offers a protection from the seepage of water through expansion or contraction joints and cracks in the masonry which cannot be secured by any other. For this reason it is largely used for waterproofing subways, arches, solid floor bridges, retaining walls, basements, pits, etc. It is also largely used in important structures in connection with some integral form of waterproofing as a precaution

against seepage of water through cavities that may occur in the masonry.

Although waterproofing by the membrane method has been unsuccessful in many cases and many reports of failures are returned by the railroad companies, the better methods of membrane waterproofing now in use are giving excellent results. The character of the structure is frequently the greatest drawback to the life of the waterproofing. The greater the number of projections and irregularities in the surface to be waterproofed, the more the liability of leaks. Many times the design of the structure is such as to make it impracticable to waterproof in a permanent manner. Sudden slopes or deep drops between the different elevations of the floor often cause the protection to slide, with a consequent tearing of the waterproofing. Often on railroad bridge floors the waterproofing is destroyed by the creeping of its protection under traffic; on arches or sharply inclined surfaces by its movement due to the settlement of the fill. In many cases the labor employed is quite unskilled and the results are obviously poor. Another factor in the success or failure of waterproofing is the state of the weather. In cold weather the heated materials cool too rapidly. In very damp or rainy weather it is impracticable to make a good job of waterproofing, unless some protection from the weather is provided. Other causes of failure are the lack of free working space and interruption by traffic. Any of these causes may lead to failure, even with the best materials.

Materials.—The materials of membrane waterproofing and the combinations that have been used most successfully by the various railroads are as follows:—

Wool felt impregnated with either asphalt or coal tar pitch.

Wool felt impregnated with either asphalt or coal tar pitch and skin-coated with the same material.

Wool felt impregnated with coal tar pitch and reinforced with a thickness of cotton drilling cemented to the felt with coal tar pitch.

Asbestos felt impregnated with asphalt.

Burlap, both plain and impregnated with either coal tar pitch or asphalt.

Mined or lake asphalts.

Petroleum asphalts.

Coal tar pitch.

Two to three layers of felt cemented together, used generally for damp-proofing and for the backs of retaining walls or foundations where no provision for a head of water is necessary.

Four to six layers of felt cemented together, used generally for railroad bridge floors, arches, tunnels subways and for a protection from a head of water.

To add tensile strength to the waterproofing, the following combinations are commonly used:—

One middle layer of reinforced felt or burlap and four layers of felt, all cemented together.

One layer of felt, two layers of burlap and two layers of felt cemented together.

Three layers of burlap and one top layer of felt cemented together.

Combinations of coal tar pitch and asphalt-treated felt or asphalt and coal tar-treated felt should not be used as the materials will not combine.

In using burlap it is recommended that burlap impregnated with either asphalt or coal tar pitch be used, otherwise, owing to its nature, it is impracticable to prevent the absorption of moisture when the material is exposed to the weather. Moisture promotes rot and also greatly reduces, or, if present in any quantity, prevents the bond of the hot cementing material and its penetration of the pores of the burlap. On the other hand, the treating of burlap promotes the bond and penetration as the treating materials in the burlap are softened on the application of the hot cementing material, and the whole becomes united in one mass.

The use of burlap with cementing material, whose temperature on application exceeds 450° F., is not recommended, as the higher temperatures are likely to result in burning and destruction of the burlap.

In many cases it is desirable to bond the waterproofing to the surface. This is not desirable in the vicinity of expansion joints or where there is likely to be a movement of the surface. At such points special provision must be made in the waterproofing to allow for expansion.

Protection.—To protect the membrane from injury it is necessary to provide a covering of some hard material that cannot be penetrated by ballast, tamping picks nor by sharp stones. Of the various methods, the following three have been the most widely used:—

(1) Brick laid flat in the hot cementing material with joints poured with the same material, or brick laid in cement mortar. On comparatively flat surfaces, brick is practicable with a bituminous binder, but on steep surfaces or slopes, the tendency to creep in hot weather makes it unsuitable. One great advantage of brick is that it can be laid quickly and easily under traffic. Brick, if used on large areas or on the extrados of an arch or on steep slopes, should be laid in cement mortar to prevent creeping.

(2) A cement mortar coating about 2 ins. thick, reinforced with wire mesh, forms a good protection and can often be used to better advantage where there is a tendency of the protecting materials to creep. This protection is recommended for arches and tunnels.

(3) A bituminous binder not less than 1¼ ins. thick, consisting of asphalt or pitch mixed with sand, gravel or fine crushed stone and applied over the waterproofing, has often been successfully used. If this is used, it should be of such consistency in hot weather as to prevent runs and the stones forcing through the protection to the waterproofing. It is not recommended on steep slopes.

Specifications.—The following specifications for five-ply waterproofing is typical of those in use by the various railroads, and applies equally well to combinations of felts and burlaps or felts and reinforced felts:

The surface on which the waterproofing is to be applied shall be dry and free from all sharp projections or irregularities of any character other than those shown on plans.

If it is desired to secure the waterproofing to the surface this surface shall be given one coat of hot cementing material mopped on uniformly, which coating shall be thin enough to penetrate the recesses, and in the case of concrete, to form a bond for the subsequent waterproofing coating. In order to insure the adhering of this coating it is advisable, in cold weather, to first heat the surface with hot sand, which is to be swept off as the cementing material is applied, or a priming coat of the cold cementing material which has been thinned with a suitable solvent may be applied.

On this first coat shall be applied a heavy coating of hot cementing material, into which shall be laid, shingle fashion, two layers of felt lapped one-half the width of the felt and cemented together with cementing material. The surfaces of the two-ply felt thus formed shall be mopped uniformly with hot cementing material and followed with three layers of felt laid shingle fashion

in this material and lapped two-thirds of its width. The surface of the five-ply felt thus formed shall be given one heavy coat of cementing material, making a five-ply waterproofing membrane all thoroughly saturated, cemented and bonded together.

In the courses thus built up it is important to have the moppings of cementing material uniform, so that felt shall not touch felt at any point and to insure a surface free from all folds and pockets.

At girder webs or around gusset plates, corners, or over column connections and expansion joins, the waterproofing membrane shall be reinforced with at least two thicknesses of felt.

Over the surface of the membrane shall be placed a protection of either brick, bituminous binder or concrete, plain or reinforced.

Cost.—Cost of membrane waterproofing varies greatly with conditions. A five-ply membrane waterproofing, with asphalt-treated felts cemented with asphalt, will cost from 25 cts. to 45 cts. per square foot, including a bituminous binder or brick protection and labor. A five-ply membrane waterproofing, using four layers of coal tar pitch-treated felt and one layer of felt reinforced with cotton drilling, cemented with coal tar pitch, will cost from 20 cts. to 35 cts. per square foot, including bituminous binder or brick protection and labor. A four-ply membrane waterproofing, using one layer of asbestos felt and three layers of impregnated burlap cemented with asphalt, including 1¼-in. thick asphalt mastic protection and labor, will cost from 20 cts. to 30 cts. per square foot; cost of asphalt about $30 per gross ton; cost of coal tar pitch about $17.50 per gross ton; cost of asphalt-treated felts from $1 to $1.25 per 100 sq. ft.; cost of coal tar pitch-treated felts about 25 cts. per 100 sq. ft.; cost of reinforced felt from $2 to $2.25 per 100 sq. ft.; cost of asbestos felt about 70 cts. per 100 sq. ft.; cost of brick $8 to 12 per thousand.

Integrals.—The use of some material in small quantities, mixed with the concrete materials in order to make concrete watertight, is generally called the integral method of waterproofing.

Inert Fillers.—The addition of a small amount of fine material to a rich concrete mixture with a well-graded aggregate, decreases the strength of the concrete. The effect upon leaner mixtures is to increase the impermeability of the concrete without decreasing its strength. Fillers used should not only be inert toward the action of the cement, but also to atmospheric conditions and to water. Material containing organic matter should be avoided, owing to its deleterious effect upon the strength of the concrete.

In using inert fillers in mixing concrete only such materials should be used as have been thoroughly analyzed as to their chemical properties and effect upon the concrete both as to strength and chemical action. The amount of inert fillers used must be determined by careful tests.

The waterproofing effect of inert fillers depends upon the void-filling quality of the material used and upon the grade of workmanship insisted upon; the addition of a waterproofing compound to the concrete material coupled with poor workmanship will not assure watertight concrete.

It is an open question whether it is good engineering, especially on important structures, to omit precautions and methods of workmanship, which improve the quality of the resulting concrete in any respect, in order to reduce the cost and produce a somewhat inferior concrete which meets the present needs. There is a possibility that in gauging the amount of money to be spent in making concrete by the strength required, other factors may be lost sight of which may in time prove harmful to a structure which was supposed to be of the most durable construction.

There are numerous examples on record where structures have been built of concrete, in the too often used haphazard method of selecting proportions and aggregates and by inferior workmanship, due to lack of proper supervision, or lack of judgment, and feeling of responsibility, with the idea that concrete is concrete, which will withstand any usage as good masonry construction. This is a wrong conception of the importance of this class of work. The selection of proper proportions and well-graded aggregates of good quality, coupled with good workmanship, the proper consistency of the mix and the thoroughness of the mixing, depositing, compacting and spading are factors which must be considered and insisted upon if a good, dense, strong and durable concrete is to be obtained.

With such precautions employed, inert fillers or compounds used in the proper proportions, impermeable and good concrete should be obtained.

In presenting results of tests of waterproofing materials added to the ingredients of concrete, the proportions of the mixture are at times stated in two different ways. One method is to state that a certain proportion of waterproofing material was mixed with the cement and then the proportions of the test specimens are given as so much of the cement mixture to aggregate. Other tests are described in which an amount of waterproofing material equivalent to a certain percentage of the cement used is added to the concrete materials. The results of such tests cannot be correctly compared without reducing them to a common ratio between cement and aggregate.

When dry compounds are used from 1 to 2½ per cent. of the cement used is recommended by the manufacturers, while for the liquid compounds from 4 to 8 per cent. of the amount of water used is recommended by them.

The cost of concrete is increased by the addition of such materials from 80 cts. to $1.20 per cubic yard for dry compounds and from 50 cts. to $1 for the liquid compounds, per cubic yard of concrete.

Active Fillers.—Compounds which are added to the concrete mixture and which react with certain of the constituents of the cement to form other compounds which will be inert and fill the voids are included in this class. In general these materials are soaps and saponifiable oils. Inasmuch as the waterproofing effect of these materials depends upon a reaction which may or may not take place, objection has been made to their use.

(To be continued.)

On April 9th, M. Beatty and Sons, Limited, launched at Welland, the dipper dredge they are building for the C. S. Boone Dredging and Construction Company of Toronto. This dredge is of steel, 100 ft. long, 40 ft. wide, 10 ft. deep at bow, and 8 ft. at stern. It is of the crane type, the crane being 40 ft. long. The dipper is of 5 cu. yd. capacity, the dipper handle being 61 ft. long, which will allow it to make 40 ft. of water. The main engine is double cylinder 15 in. bore and 15 in. stroke. The boiler 10 ft. diam., by 12 ft. long, of the Scotch marine type. Each bow anchor or spud is operated by an independent reversible engine of 10 in. bore by 10 in. stroke, compound geared, the anchors being raised and pinned up by steel cable. The engine for handling the stern anchor is 9 x 9 in. compound geared. Located on [illegible] side of the deck forward, is a [illegible] in. double cylinder, triple drum engine, which is used for warping the dump scows into position. It is expected that the dredge will be completed and ready for towing by May 1st.

CONTENTS OF THIS ISSUE.

OPPORTUNITIES FOR ENGINEERS.

Some very commendable food for thought is to be found in the presidential address of Frederic H. Fay, of the Boston Society of Civil Engineers. At the recent annual meeting Mr. Fay, whose associations with engineers over a number of years as division engineer at Boston for the United States Public Works Department, emphasized, as a quality of highest importance to the success of the young engineer, the ability to properly meet and mingle with his fellow-engineers. He should be, in popular vernacular, a "mixer," and to failure in this direction is accorded the lack of, or limited, success of many an engineer who has the other requisites, and who but for this discrepancy would undoubtedly achieve a far higher position.

To meet the demands which are born of dependence and reliance upon them in every field of activity, engineers must grow and become broader men.

The successful engineer of to-day and of to-morrow cannot be like the engineer of yesterday, who too often would retire into the technical recesses of his professional work and content himself with being the servant of other men. The engineer of to-day should be a broad-gauge man, aggressive, alert, in touch with public questions outside his own narrow field, and a leader—not a follower—of men. It is upon the development of these qualities in engineers themselves that the whole future success of the profession depends.

"The engineer should be a manager, and should give orders to others who can do the work under his direction as well as he himself could do it with the situation reversed. It should not be considered unprofessional for an engineer to be a capitalist, and, when he takes his proper place as promoter and organizer and shares in the profits of engineering enterprises, he will no longer be taunted with the saying that 'an engineer is only good to spend other people's money.' It is by acquiring individual strength that the engineer can give strength to the profession. It is well known that engineers of admitted proficiency often have to work under the direction of men who are unfitted by education and experience to direct engineering work. This is because the engineer is a workman while the other party belongs to the class of 'managers.' The engineer has not reached his proper rank until he can hold the position of manager, as well as that of a designer and supervisor of work.

"Engineers themselves are frequently responsible for the low estimate which the public places upon the value of engineering services. Chief engineers of corporations and public boards too often make the mistake of hiring engineering assistants at the lowest possible wage, under the false impression that by such rigid economy they are enhancing their own value in the minds of their employers. Many of us can name instances where young engineers of much ability and good training, but of somewhat limited experience, have been placed in charge of important pieces of work at salaries less than the lowest wage paid to skilled workmen employed by the contractors working under their direction.

"Such practices do grave injury to the whole profession and cheapen it in the estimation of the public. Furthermore, they tend to react to the disadvantage even of the chief engineer, for his employers will reason that if the rank and file of engineers can be hired so cheaply, engineers as a whole are a cheap lot, and high salaries are not necessary in any grade, even that of the chief engineer himself. The chief engineer who pays a fair wage, taking account of the time and money which the young engineer has spent in securing his education and

training (his working capital), will not only secure better, more loyal and more efficient service, but will help to raise the standard of the whole profession."

SASKATCHEWAN HIGHWAY IMPROVEMENT IN 1914.

The Provincial Highways Commission of Saskatchewan has a larger programme before it this year than ever before. This is perhaps owing to the fact that it is undertaking work which until this season has been carried on by the municipalities themselves. The road appropriation for the current year amounts to $1,500,000, one-third of which is to be devoted to bridge construction. Of this the Saskatoon high level bridge will come in for a considerable share, while approximately $100,000 will be spent on small bridges of steel and concrete similar to those described and illustrated in *The Canadian Engineer* for January 8th, 1914.

The Commission announces that by June 1st, approximately one hundred road gangs will be at work in the province.

INTERNATIONAL CONFERENCE ON CITY PLANNING.

During the last five years national conferences on city planning have been held annually in various cities of the United States, and have aroused such widespread interest that many American communities are now anxious to have the conference held in their city and are willing to contribute the funds for that purpose. The City of Toronto, therefore, is to be congratulated on being the first place on this side of the international boundary to entertain the conference, which this year will become international in scope and character. The financial difficulties have been overcome by a generous grant from the Dominion government, which has appointed the Commission of Conservation to act as hosts. The Ontario government and the City of Toronto are also contributing. The question of city planning is thus recognized to be of national, provincial and municipal concern. The Governor-General will open the conference and give an address.

The substantial assistance given by the Dominion government is evidence that the town-dweller, equally with the agriculturist, is receiving attention, and that not only the federal capital, but all our Canadian cities are receiving from the federal authorities such advice and assistance as the Congress will afford them. Invitations have been sent to all the cities and towns in the Dominion, requesting them to send delegations to the conference. It is felt that money could be spent to no greater advantage than in giving some of our city councillors the opportunity to come into touch with experts in civic problems from all over the continent. The aldermen will carry home ideas that, put into practice, will save their townspeople millions of dollars, besides acquiring a new sense of the responsibilities of their office and higher ideals of civic administration.

The scope of the conference may be gauged by a glance at some of the topics which will form the main themes of discussion. Among these may be cited: "The Relative Importance of City Planning as Compared with All Other Functions of City Government," by Andrew Wright Crawford, editor of the city-planning section of the Public Ledger; "Provision for Future Rapid Transit," by J. V. Davies, consulting engineer for the Brooklyn Rapid Transit Company; "Rapid Transit and the Auto Bus," by John A. McCollum, assistant engineer, Board of Estimate and Apportionment, New York City; "Protecting Residential Districts," by Lawrence Veiller, secretary and director of the National Housing Association, New York City; "Toronto's Water Front Development," by R. S. Gourlay, of the Toronto Harbor Board; "A Consideration of the Principles and Procedure of a Canadian Town-Planning Act," a draft of which is now being prepared by a special committee appointed by the Commission of Conservation; and "Recreation Facilities in the City Plan," by Henry V. Hubbard, professor of landscape architecture in Harvard University.

DIFFERENCE IN DENSITY IN PANAMA CANAL WATERS.

It is announced in the Canal Record of April 8th that forces of the meteorology and hydrology subdivision are making a study, at the lower end of Miraflores Locks, of a current caused by the difference in density of the water on two sides of the lower gates when the gates are opened for the passage of vessels to the sea. At the stage of a downward lockage when the surface of water in the lower chamber has been lowered to evenness with that in the approach, the water within the chamber is more than half fresh. It has, in consequence, less density than the sea water beyond the lower gates and when the gates are opened the heavier water thrusts its way inward against the lighter, causing a current opposed to the outward passage of a vessel.

Surface indications are that the current has a velocity of from three to four miles per hour. Being temporary, it causes no serious inconvenience and it is being studied principally to determine accurately the conditions for the manipulation of the towing locomotives. The density of sea water is about 2.5 per cent. greater than that of fresh water; a simple illustration of the difference is seen in the fact that chewing gum will float in sea water, but not in fresh. At the lower end of the locks, the difference in density of the water on both sides of the gates is less, because a considerable proportion of sea water is mixed with the fresh water in the lower chamber before the lower gates are opened. The conditions exist only at Miraflores and Gatun Locks, the water at both ends of Pedro Miguel Lock being fresh at present.

EDITORIAL COMMENT.

In commenting upon the question of contract vs. day labor in municipal work, as referred to editorially in *The Canadian Engineer* for January 22nd, the following observations appeared recently in "The Sanitary Record and Municipal Engineering" (England):—

As to how far English municipal engineers agree with the cogent reasoning which we have quoted we must leave it to them to speak for themselves. The practice which obtains in Canadian cities of the city engineer's department tendering in competition with contractors—a practice which does not obtain in this country—constitutes, it is asserted, a stimulant to the department and prevents a deterioration of organization, limits increase in the cost of work, and establishes a formidable reason for the employment of efficient and well-paid men, and is one which might perhaps advantageously be adopted in this country.

AMERICAN WATER WORKS ASSOCIATION.

The 34th annual convention of the American Water Works Association to be held in Philadelphia during the week of May 11th, will bring together some very prominent engineers, waterworks superintendents and manufacturers of machinery and supplies. The association has a considerable membership in Canada and the convention is commanding the attention of waterworks men throughout the entire Canadian field. No doubt the forthcoming convention will be attended in large number by Canadians interested in the papers, discussions, privileges and opportunities which it will present.

Preparations for the convention are practically completed. The headquarters will be at the Bellevue-Stratford, Philadelphia. The programme of papers is unusually interesting; advance copies have been issued, and discussions are being submitted by letter or prepared for presentation at the convention. One day has been set aside as Superintendents' Day—a decidedly good feature. A few short practical papers by waterworks superintendents will be presented.

The following are among the papers to be read and discussed at the other sessions:

"Investigations Into the Advisability of Substituting Agar for Gelatine as a Medium for the Determination of Bacterial Counts in Water Analysis," by W. U. C. Baton, Analyst in charge of Pittsburgh Laboratory.

"Sewage Pollution of Boundary Waters," by Allan J. McLaughlin, M.D., Surgeon, U.S. Public Health Service, Chief Sanitary Expert and Director of Field Work for the International Joint Commission.

"Present Day Water Filtration Practice," by George A. Johnson, Consulting Engineer, New York.

"Remarks on the Theory of the Pitot Tube," by N. W. Akimoff.

"Testing of Check Valves," by J. Walter Ackerman, Superintendent, Water Board, Auburn, N.Y.

"Equitable Hydrant Rentals and Better Methods for Apportioning Fire Protection Cost," by John W. Alvord, Consulting Engineer, Chicago, Ill.

"Use and Benefits of Pressure Recording Gauges," by J. M. Diven, Superintendent, Troy Waterworks, and Secretary of the Association.

"The Water Supply at Wilmington, Delaware," by Edgar M. Hoopes, Jr., C.E., Chief Engineer of the Water Department, and James M. Caird, Consulting Chemist and Bacteriologist for the Water Department.

"The Croton Water Supply: Its Quality and Purification," by George W. Fuller, Consulting Engineer, New York.

COST OF ROAD CONSTRUCTION IN UNITED STATES.

In 1904 the total expenditure on all public roads in the United States was $70,771,417. In 1912 the expenditure amounted to $164,232,365, more than twice as great. The expenditure per mile on public roads in 1904 was approximately $37.07; in 1912 it was $74.65. The expenditure per inhabitant in 1904 was $1.05; in 1912, $1.78.

The greatest progress in road-building has been made in the states which contribute from their treasuries toward the construction of state aid or trunk line roads. In 1904 there were thirteen states that contributed out of a general fund $2,607,000; in 1912 there were thirty-five states which contributed $43,757,438.

RANSOME FILTER RECOMMENDED FOR ADDITION TO TORONTO FILTRATION PLANT.

John ver Mehr Engineering Company, Limited, as Engineers, and William Cowlin & Son (Canada), Limited, as Contractors—Cost $1,066,282.

COMMISSIONER of Works R. C. Harris, of Toronto, has recommended to the Board of Control that a contract be awarded to the John ver Mehr Engineering Company, Limited, as engineers, and William Cowlin & Son (Canada) Limited, as contractors, for a $1,066,282 addition to the Toronto Island filtration plant. The Board of Control has approved of the recommendation and it will be discussed at the next Council meeting.

The existing plant is of slow sand design, while the new plant recommended is the Ransome drifting sand system. The plant will filter sixty million Imperial gallons per twenty-four hours, and may be overloaded to the extent of twenty per cent. for any period of ten hours.

The plant, as proposed, consists of ten filter units, and occupies approximately 2.4 acres. The nearest point is situated approximately 170 feet to the west of the westerly wall of the existing slow sand filters. The buildings consist of coal storage, chemical storage, chemical building, suction well and building, boiler house and pumping station, filter house and wash water tank. The coal storage, chemical storage and chemical house are under one roof. The suction well, boiler house and pumping station, filter house and wash water tank are separate structures. The coal storage building is connected to the boiler house by a passageway, while like connection is made between the pumping station and filter house. The coal storage, chemical storage and chemical building is to be constructed of concrete, while the others are to have concrete foundations with pressed brick walls and tile roofs.

Connection is made from the two existing 72-inch intakes by two 5/8 inch steel pipes of like dimensions, surrounded by 12 inches of concrete, conveying the water to the suction well, which is equipped with a system of double screens, and a gate valve, hydraulically operated, at the end of each intake. From this well, suction pipes run to three 36-inch centrifugal pumps, electrically driven. These suctions are placed so that water may be drawn from elevation 30, or 10 feet below zero lake level.

The sulphate of alumina coagulant is introduced to the raw water in pre-determined quantity, prior to its entering the suction well, and may be varied according to the quantity of water passing.

From the three centrifugal pumps, the water passes to the filters through a 72-inch steel pipe, diminishing at the extreme north end of the filter house to 36-inch. This conduit is supplied with a 72-inch Venturi meter, which automatically indicates, integrates and records the water passed.

The system comprises practically a combination of the slow sand and mechanical methods. The water is carried from the supply pipe previously mentioned, to the top of ten steel cylinders, each having an outside diameter of 50 feet. In the centre of each of these cylinders there is an open space of circular form, 16 ft. 8 in. in diameter, which accommodates the supply piping, the sand washer, and sand conveyer.

The operation is described by the ver Mehr Company as follows:

"The distinctive feature of the Ransome Drifting Sand Filter is the employment of a gradually moving body of sand as the primary or roughing filtration medium, which eliminates as a continuous process the main impurities from the water prior to its passage through the final filtration medium or stationary sand. Governed by its natural angle of settlement, the moving sand almost imperceptibly gravitates, grain by grain, towards a system of collecting or extracting points at the bottom of the filter, arranged in a system so as to divide the filter into thirty equal sections. The sand with added water then passes to a central collecting point and is elevated to a sand washer placed centrally at the top of the filter, where, after being thoroughly and automatically cleansed of its impurities, it will be continuously caught up by the incoming water and deposited again on the moving sand surface at the top of the filter. The stationary sand forms naturally into pyramidal shapes with rounded tops offering a large surface to the passage of the filtering water. This surface is more than twice the plan area of the filter. The stationary sand rests upon gravel, from which it is separated by perforated brass screens, and the water is collected from a number of brass and cast iron collecting pipes from the bottom of each of the thirty sections.

"The elimination of the main impurities by the moving sand will enable this filter to carry on a continuous filtration process without washing back for periods of about one week, thus assuring continuous and practically uniform results.

"The loss of head in the filter gradually increases from a minimum of 5 feet at the commencement of a run to a maximum of 12 feet, when it becomes necessary to wash back the filter with a high-rate wash of fifteen gallons per square foot per minute, using filtered water, for which an overhead tank, with duplicate pumps to fill it, will be provided. The slow rate at which the filters clog, removes the desirability of providing rate controllers, as all that is necessary is that the attendant should adjust the main outlet valve once or twice a day to the desired requirement.

"The operation of the sand extractors is such that they are controlled by the raw wash water, which, if shut off, causes the extractors to cease operating and when the water is supplied again, to start working as before.

"With this type of filter the need for coagulating and sedimentation basins is avoided; indeed, as proved by the slowness of the clogging of the stationary sand and the efficiency of filtration, the drifting sand is much more effective in removing the impurities than sedimentation basins. Thus it is not proposed to provide mixing, coagulating or sedimentation basins, but to apply the coagulant to the main raw water pipe opposite the chemical house. The mixing of this coagulant with the water will be perfect in that it will first of all have to pass through the suction well, where it will receive considerable natural mixing and afterwards through the pumps, where the mixing with the raw water will be complete. Further intimate mixture between the sulphate of alumina and the raw water takes place at the sand washer and the distribution pipes, so that by the time the water reaches the filter a thorough mixture is absolutely assured."

Approximately two per cent. of the raw water supply is used to wash the drifting sand, says Commissioner Harris. The stationary cone is back washed with filtered water, which is estimated by the ver Mehr Company at one per cent. of the effluent. The sand in each filter has a depth of 9 feet.

The filter units are made of steel, supported by columns, and all of the valves are controlled hydraulically from operating tables placed on a central elevated gallery, located between the two lines of filters and on a level with the top thereof.

Extending around the periphery of each filter is an overflow in view of the operator, who controls the supply accordingly. This overflow returns to the suction well.

The water from the filters discharges into steel mains through an indicating, integrating and recording Venturi meter, and travels thence by steel main to a point 50 feet north of the filter house, where it is discharged into the present clear water reservoir connected to the slow sand filtration plant, by a conduit to be laid by the city.

All of the apparatus in connection with these filters is enclosed by buildings erected on existing ground.

The tenderers agree to complete and put in operation one-half of the plant by August 1st, 1915, and the whole by November 1st, 1915. All of the structures are to be erected on existing ground, no new sand fill being required.

Commissioner of Works R. C. Harris, in his report to the Board of Control recommending the acceptance of the ver Mehr Company's tender, said that he believed the only considerable hazard which may eventuate during the construction period, would be caused by reason of the excavation for the additional plant being carried to a depth below that of the existing filters. When the ground water is removed from the excavation for the purpose of constructing the foundations, the flow of water from the present plant might cause a sand movement which would diminish the present stability of the filter beds. The contractors have made provision for carrying out the work in a manner which should eliminate this danger. They propose to drive sheet piling along the entire west side of the excavation—that is, the side nearest the westerly wall of the existing plant. By this means it is felt that serious sand movement will be obviated.

The specifications under which tenders were called were most severe as regards bacterial efficiency. The ver Mehr Company guarantees that their plant will remove 90 per cent. of all organisms where there are 50 to 500 bacteria per c.c. in the unfiltered water; 95 per cent. of all organisms where there are 500 to 2,000 bacteria per c.c. in the unfiltered water; and 98 per cent. of all organisms where there are 2,000 or more bacteria per c.c. in the unfiltered water. There is also guaranteed the removal of 98 per cent. of the B. Coli. All turbidity must be removed, leaving a bright, colorless water free from taste. These results are guaranteed with the use of not more than one grain of alum per Imperial gallon of water under average conditions.

The ver Mehr and Cowlin companies were unable to secure insurance bond covering these guarantees of bacterial efficiency, but offered their personal bond, guaranteed by their parent English companies, for $250,000, indemnifying the city against any failure in this connection. They have arranged with English insurance companies for the necessary bond covering the balance of their guarantee and responsibilities.

It is understood that the ver Mehr and Cowlin companies were the only tenderers for the plant willing to accept the contract with clause 200 included. This clause, which some thought might be confiscatory under certain conditions, reads as follows:

"The plant shall be fully tested for clarity of effluent and bacteriological efficiency, by the Medical Officer of Health or his representative, within three months after

the plant, or portion thereof, has been placed in operation, and in the event of failure to fulfil the guarantees, the entire plant may, at the option of the Commissioner, be entirely rejected, and all moneys paid to the contractor shall be refunded to the Corporation, and may be recovered from the contractor or his sureties. In the event of dispute between the Medical Officer of Health and the contractor, the matter in dispute shall be referred to the Commissioner, whose decision shall be final and binding."

In the early part of 1913, Mr. John ver Mehr submitted a proposition to the City of Toronto covering the erection, without cost to the city, of a demonstration Ransome filter at West Toronto, to filter the Humber Bay water.

With the consent of Council, this plant was built and operated under the direction of the Medical Officer of Health and of Dr. G. G. Nasmith, Director of Laboratories, for thirty-three days during last summer. In reporting on this test, Dr. Nasmith said that daily analyses of the water before treatment on Standard Agar was 1,458 per c.c., while the effluent showed 15 bacteria per c.c., giving a total bacteria removal of 99 per cent. B. Coli. was removed to the extent of 98 per cent., while 99 per cent. of the red colonies growing on the neutral red bile salt agar (Dr. Houston's formula) were removed. The amount of alum used varied from .85 grain to 1.5 grains per Imperial gallon. "The effluent," said Dr. Nasmith, "was invariably bright and sparkling, without any trace of turbidity."

Commissioner Harris says that this test was made with water from Humber Bay which was of a uniformly bad quality. During a portion of the time the unit was under test, the city officials increased the turbidity of the water to a point beyond that found in the water at the intake mouth, south of the Island, when at its worst. The test unit at West Toronto was of one-half million Imperial gallons daily capacity.

FORESTRY CONVENTION IN NOVA SCOTIA.

For five or six years, those interested in the forests of Nova Scotia have been endeavoring to secure the annual Convention of the Canadian Forestry Association, which has hitherto been held east of Fredericton, N.B. This year the Government of Nova Scotia invited the Canadian Forestry Association to meet in Halifax, and discuss the forest problems peculiar to that province. This invitation was warmly seconded by the lumbering, farming, commercial and educational interests. At a meeting of the directors of the Forestry Association, in this city, with the president, Mr. William Power, M.P., of Quebec, in the chair, it was decided to hold the convention in Halifax, September 2, 3 and 4. Already a number of leading lumbermen and authorities on forestry from the maritime provinces, Quebec, Ontario and places further west have signified their intention of taking part. Mr. James Lawler, Ottawa, Secretary of the Canadian Forestry Association, who recently visited Nova Scotia, and who will return there in the summer to hold a series of meetings in preparation for the convention, reports great interest among the owners of timber lands in Nova Scotia in the effort to conserve this very important industry.

Reconstruction of the Brooklyn Bridge has been studied out by the Department of Bridges, New York City, in detail during the past ten years. The project has now been taken up by the Commissioner of Bridges, F. J. H. Kracke. The work in question is likely to mean the entire replacement of all the suspended structure; that is, everything except towers, tower cables, and anchorages. The existing stiffening trusses and floor are not adequate for permanent service under present overloading, and give no additional capacity for the further loading which the bridge might be made to carry.

PAINTING CONCRETE SURFACES.

THE painting of concrete and cement surfaces is one of the many new problems that modern conditions have brought to the master painters of the present day. Ordinary linseed oil paints cannot be applied with success directly to cement or concrete surfaces on account of the lime present in the cement. The action of this alkali is to destroy the oil, causing rapid fading of colored paints, and chalking and scaling off of the material. Therefore, it is necessary, if a linseed oil paint is to be used, that the surface be first thoroughly saturated with a neutralizing wash. The most approved method is to use a solution of zinc sulphate in the proportions of 3 lb. to a gallon of water. A cement surface treated with this wash and allowed to dry can be painted with any high-grade linseed oil paint without danger from alkaline action, and with the assurance that results will be lasting, as if applied to wood.

Water color paints should not be used for exterior cement coating, as they do not form a waterproof coating (one of the most important requirements of a cement paint) and offer no protection from deteriorating influences.

All new laid cement surfaces, either exterior or interior, should be allowed to become thoroughly dried out and hard before painting, and the best results have been obtained where the work has stood not less than a month before paint was applied. If the surface is dry and the paint right, it will penetrate freely on the first coat, filling the pores and rendering peeling impossible, but this would not be the case if applied over a damp surface.

Exterior cement paints should dry to a flat or semi-flat finish in order to carry out the stone or cement effect. Nothing looks more out of place than a full gloss paint applied to exterior cement surfaces.

Many of the ready prepared cement floor paints, the quick drying vehicle of which is largely China wood oil, have been found to give excellent results. Mr. R. H. Langston, in a paper read at the Illinois State Association of Master House Painters, Chicago, strongly recommended their use until such time as a more complete knowledge of the requirements in mixing of this material can be obtained.

There is no doubt that, for some time to come, the master painter will be feeling his way, step by step, in the new realm of modern surface painting which cement construction has forced upon him. It will tax the brain of the paint chemist to formulate the vehicle with which to destroy the alkaline base with which cement surfaces are loaded.

Time and the elements are the only factors which will buy time exposure, and to arrive at the point of absolute elimination or of perfect assimilation of the vehicle with the cement surfaces that are coated, will require patient effort. We are all aware that the goal has not been reached by any means, but constant scientific research will land us in the promised land of perfection, as it is doing in every other line of industrial development.

Surface Finish for Concrete Floors.—A new method of finishing the surface of concrete floors has been recently introduced. From 15 to 30 per cent. of iron filings are mixed with the cement dry, and one part of this mixture to two parts of sand makes the material for the top coat, which varies from ½-in. to 1-in. in thickness according to requirements. It is said to make a hard, durable and non-slippery floor surface.

RAILROAD TUNNEL CONSTRUCTION AND VENTILATION.

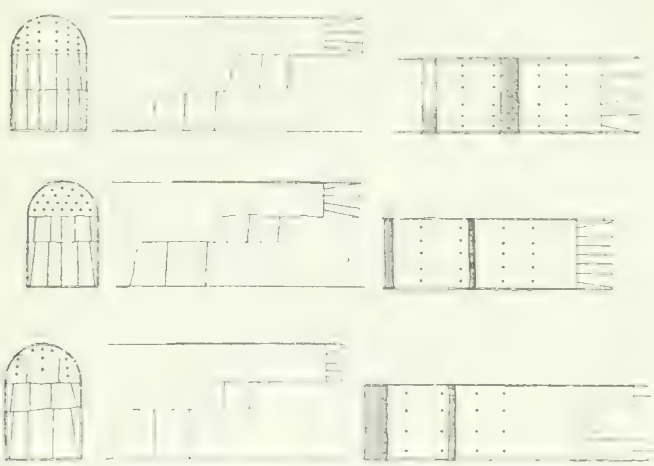
THE committee on track of the American Railway Engineering Association has presented the following conclusions after several years' study of tunnel construction and ventilation for railroads:

1. Railway tunnels, as ordinarily constructed in the United States, are more economically built by first driving the heading entirely through, but such method usually requires a greater length of time for completion of the tunnel.

2. For material requiring support the top heading should usually be driven.

3. It is economical and expedient to use an electric shovel or an air shovel for the removal of the bench where the section of the tunnel permits its safe operation; and where the material does not require support there are advantages in low cost and quick removal of the bench in driving the heading at the subgrade line.

4. Where the time limit is of value, the heading and bench should be excavated at the same time, the heading being kept about 50 ft. in advance of the bench. Where the material of roof is not self-supporting and timbering



Typical Methods of Railroad Tunnel Construction. Fig. 1 (top)—V-cut used in hard rock with few seams. Fig. 2 (centre)—Hammer-cut for moderately hard rock with seams. Fig. 3 (bottom)—Cut used in soft rock or hard clay.

is to be resorted to, the bench should not be removed until the wall plates are laid and the arch rib or centering safely put up.

5. Opposing grades should preferably not meet between the tunnel portals so as to put a summit in the tunnel. Where practicable, the alignment and ascending grades in the tunnel should be in the same direction as the prevailing winds.

6. The accompanying drawings are representative of American practice in single-track tunnel construction, where the time limit is of value.

Explanation of Figures.—The typical method in hard rock with few seams is shown in Fig. 1. The heading in material of this kind is usually driven by a V cut, using from sixteen to twenty-two holes about 8 ft. deep. The holes near the middle of the heading are drilled so as nearly to meet at the end. These holes are shot first, then the second row and lastly the outside holes. The arrangement of these holes will vary slightly, according to the way the material breaks.

The bench in material of this kind is usually taken out in two lifts of almost equal weight. The sub-bench is drilled from 20 to 40 ft. in advance of the bench. From four to eight holes in a row, with 6 or 8-ft. face, are used in both sub-bench and bench. One or two rows of holes may be used. The centre holes are shot first and the side holes last.

For moderately hard rock with seams the method outlined in Fig. 2 is employed. The heading is usually driven by a "hammer" cut, using from fourteen to twenty holes 6 to 10 ft. deep. The bottom row of holes is inclined at an angle of about 30 deg. The rows are shot in succession, beginning at the bottom. The holes should be arranged to suit the seams in the material.

The bench is sometimes taken out in one lift, but usually in two, with the sub-bench not as deep as the bench. The sub-bench is best drilled from 20 to 40 ft. in advance of the bench. From four to six holes in a row may be used with from 6 to 10-ft. face. The centre holes are shot first and the side holes later.

The method indicated in Fig. 3 is used only when the material is so soft that the heading cannot be driven for the full length of timber used for the wall plates. Drifts about 4 ft. wide and 6 ft. high are driven for each wall plate, and the core is taken out as the timber rings are put in. Three or four holes from 3 to 5 ft. deep may be used in each drift. The amount of shooting necessary depends entirely upon the softness of the material, which can often be picked. The core may be soft enough to pick, or may be shot with from four to eight holes, drilled either from the face as shown or from the sides of the drifts.

In this class of material the bench is shot in one or two lifts. Only a few holes are necessary.

Tunnel Ventilation.—Most practicable, effective and economical artificial ventilation for tunnels carrying steam-power traffic is to be obtained by blowing a current of air into one end of the tunnel for the purpose of removing, or of diluting and removing the smoke and combustion gases at the opposite end. As practised in America, this way of procuring ventilation partakes of two methods:

1. To blow a current of air in the direction the train is moving and with sufficient velocity to remove the smoke and combustion gases ahead of the engine.

2. To blow a current of air against the direction of the train with velocity and volume sufficient to dilute the smoke and combustion gases to such an extent as not to be uncomfortable to the operating crews and to clear the tunnel entirely within the minimum time limit for following trains.

RAILWAY CONSTRUCTION IN SIAM.

The Director-General of the Siamese Railway Department is the authority for a report of steady construction work on the Siam Northern line. The railhead is now at kilometre 476, so that only 190 kilometres (kilometre = 0.62 mile) now separate Chiengmai from railway communication with Bangkok, the capital. Lao (Northern Siamese) labor is employed where formerly Chinese labor was considered indispensable, and the results are most satisfactory. Operations are progressing in two divisions, one from railhead to Lampang, the other from Lampang to Chiengmai. The Meh Yome bridge is completed, and in the meantime track laying is going forward on the other side of the Meh Yome and has progressed 16 kilometres. The 1,400-foot tunnel at Pang Pakan, pierced several months ago, is being lined and will be completed by the time the railhead reaches there. Koon Tan, a 4,265-foot tunnel is being pierced, 1,200 feet having been completed.

THE DIESEL ENGINE.*

ALTHOUGH the progress made has been to some extent disappointing, the Diesel marine engine is finding increased employment in sea-going vessels. Great Britain has hitherto played a comparatively small part in this development, but several British firms are now undertaking the manufacture of such engines, and Burmeister & Wain, the Danish engineers who have had so much to do with the development of the system, have established works on the Clyde. The current year should witness a considerable addition to the number of oil engine ships. From 15 to 20 new large motorships were put into service. The engines fitted are of the two-stroke or the four-stroke cycle. Those in the former class include some of the largest vessels yet fitted with Diesel engines, such as the "Hagen," of 5,460 tons, the engines for which were supplied by Messrs. Krupp, and the "Wotan," of 5,703 tons, while the four-stroke cycle vessels include the "Siam," of 5,296 tons, the "Annam," of the same tonnage, and the "Fionia," all engined by Burmeister & Wain. The last vessel is the most powerful. She is equipped with two 2,000-i.h.p. Burmeister & Wain Diesel motors of the four-cycle type, and the power of each of these motors is as high as any yet constructed for marine work.

It is felt that the four-cycle engine has made far greater strides for ship propulsion than was first thought would be the case when the motorship made its appearance. Moreover, the results which have been obtained from motor-vessels in which this type of engine is installed have, on the whole, been rather more satisfactory than those with the two-cycle engines. With regard to the latter type, a good deal of difficulty has been experienced owing to cracked cylinder covers and also cylinder liners. Cast steel, which was employed in certain cases for cylinder heads, has been abandoned, and with the special cast iron now generally employed the cracking has been largely abolished.

Air-Compressor Troubles.—Experience in service has shown, however, that the main trouble which has arisen in the marine Diesel engine is with the air-compressors. Several serious breakdowns have been attributed to the presence of oil in the air-compressors, and the explosions which have taken place in one or two instances with compressors of good design can be explained only by the breaking down of the oil of very high flash point which has been employed. Investigation has shown that under a combination of high temperature and pressure the oil had become carbonized. The danger is a very real one, but the problem is one which ought not to be difficult of solution, and it has been suggested that a committee should investigate the whole subject and devise methods for the employment of more suitable lubricants to overcome a trouble which if not remedied will seriously retard the progress of the Diesel marine engine. That progress is already checked by the high price of oil fuel, and if technical difficulties are added to commercial disadvantages the outlook will be heavily clouded.

In this country Messrs. Swan, Hunter and Wigham Richardson have fitted Neptune Diesel engines to the cargo vessel "Arum." The machinery in this case consists of two sets of reversible single acting Diesel oil engines of the marine type working on the two-stroke cycle. The engines are rated at 1,150 h.p. This ship is the first of a fleet of the same type. At Dundee two vessels under construction are to be fitted with Diesel engines of 2,000 and 2,200 h.p. respectively. Messrs. Beardmores have supplied crude oil engines for some small ships, and Messrs. Yarrow have also done work in this field. It is understood that one of the ships being built at Harland & Wolff's Glasgow yard is to be fitted with Diesel engines. A large number of small ships have been fitted with marine oil engines of other types than the Diesel. The Kromhout is one which is now being largely employed, the ease of reversing associated with it having brought it into favor.

Oil Engines in Warships.—Apparently little progress has been made with the problem of the application of the oil engine for very large ships, and in particular for battleships, although experimental work is progressing favorably with two or three firms interested in this question. It is hoped in Germany that two 12,000-h.p. Diesel motors will be completed before the end of the current year, after which the problem of the motor-battleship may be advanced a step further. Submarines are now practically universally equipped with Diesel engines, and there is a distinct tendency to increase the size and power of these motors. Although during the past year none of the submarines for any country had greater power than 2,000 h.p. on twin screws, engines are being built in the chief European countries in units up to 2,000 h.p. for installation in a much larger type of submarine than has hitherto been common. It can, however, by no means be guaranteed that these engines will be a success, as the difficulties involved are excessive owing to the high speeds of revolution necessitated by the limitations of space and weight.

The Diesel Motor.—Engineering development is not always mainly dependent upon the engineer, who may be restrained by a number of commercial considerations which he is by no means able to control. This appears to apply particularly to the case of the internal combustion engine, the progress in which must inevitably be largely determined by the price at which the necessary fuel is available. For this reason, the high price of oil which has prevailed in Europe during last year had a distinctly detrimental effect upon the progress of motors using this fuel, and there can be no doubt that the oil-engine trade so far as this country is concerned, would have been much larger had the anticipated reduction in the price of heavy oil been made. Present indications do not point to any marked change in this direction, but greater attention is being paid to the utilization of tar oil, which is widely employed on the Continent, and possibly in a year or two's time there may be a modification in the existing circumstances.

Gas Engines.—Despite the adverse conditions, the use of the internal-combustion motor grows more widespread, and business during 1913 was exceptionally good —probably the best on record; and while the gas-engine trade would have been still larger to-day had it not been for the advent of the Diesel (the talented inventor of which died in tragic circumstances during the year) and the semi-Diesel engines (which compete with it in the larger and smaller sizes respectively) it is nevertheless in a healthier state than ever previously. This statement refers mainly to the producer-gas engine, although the use of coke-oven and blast-furnace gas for motive power has shown considerable increase. There is still much to be done in this direction, and manufacturers may regard it as one of their best spheres, for the economy in operation at mines and steel works is very great. This point is all the more to be emphasized by a consideration of a probable increase in the amount of coal which will be sub-

*Abstract from London Times Engineering Supplement, January 14, 1914.

jected to destructive distillation for the production of heavier and lighter oils. The number of very large gas-engine units built for this country has, however, not been great, but as with the present relative prices of gas and oil the gas-engine shows to good advantage in fuel costs, the demand for the small and medium powered producer-gas plant is extremely brisk.

Few novel features were introduced during the past twelve months in gas-engines, the chief point of interest being the increasing employment of fuels other than coal in places where they are readily obtainable. Sawdust is giving good results in numerous cases, while peat and charcoal are also employed with advantage when slight modifications are made in the producers. So much experience has been gained with the gas-engine during the last decade that one is inclined to consider its design as near the limit of perfection as that of the steam-engine, at any rate so far as the present-day type is concerned. But the gas turbine still remains an unsolved problem commercially, and there is absolutely no practical development to be recorded during 1913. The Holzwarth machine, from which at one time a good deal was expected, has up to the present received no real application, and although several inventors are now working on a type in which water is injected into the turbine, no definite progress is to be recorded.

Only in one phase does the development of the gas-engine seem to be at a standstill—its use for marine purposes and the hopes that were raised a few years ago are far from being fulfilled. It is now generally felt in most quarters that the future of the marine internal-combustion engine lies with the oil motor, and, although there are certain engineers who take the opposite view, their number is not great. A few gas-engine driven vessels were put into commission during the year, but apart from one motor coaster with two 150-h.p. motors, they were mainly barges with engines up to 100 h.p., and usually not much over 50 h.p. They were practically all built on the Continent, and chiefly in Holland.

Oil Engines.—Although the volume of the oil-engine business is probably no larger than that of gas-engines, the subject is one of greater interest owing to the development being more recent, with a consequent possibility of the introduction of more novelty in design and application. One fact of importance may first be noted, that the reputation of the few British firms building stationary Diesel engines has increased considerably, while the British semi-Diesel engine for land work is probably as good as, if not superior to, any built abroad. The sale of the former type in Great Britain has been very seriously affected by the high price of oil, but an increasing field in Canada, India, South America, and in other parts of the world has prevented any lull in the progress. There is a very marked tendency to favor the high-speed type in powers up to 500 h.p. for driving dynamos, pumping plants, and similar purposes, and it is quite fair to say that in spite of the difficulties which its design involved, the Diesel motor running at 250 to 350 r.p.m. is now as satisfactory a machine as the slow-speed type of 150 to 180 r.p.m. In the higher powers (750 h.p. and over) the two-cycle slow-speed engine is being favored, although the number constructed is at present relatively small. None of these (for land work) is yet being built in England, but many of the prominent firms on the Continent are doing quite well in this direction, the largest motor constructed being one of 4,000 h.p. with six cylinders, running at about 130 r.p.m., just completed by Messrs. Sulzer for Harland & Wolff. This will shortly be put into service, and its success will probably have a distinct influence on the development of the high-powered stationary oil-engine.

Semi-Diesel Engines.—The year was specially important and interesting to the manufacturer of the type known as the semi-Diesel engine—that is to say, the low-compression, heavy-oil engine. Orders were plentiful with practically all the firms of established repute, on both the stationary and the marine side, and several new types were put upon the market. There was no radical alteration in the design of any of them, nor do the new engines show any remarkable modification from the usual type. Larger powers were, however, constructed than were previously thought practicable, the biggest being one of 80 h.p. per cylinder, or 320 h.p. in four cylinders. A large number of such motors have now been built, and it seems possible that even higher powers may be obtained, although probably 500 h.p. will be the limit.

The prospects for 1914 appear to be very good, and although the amount of business done will probably not be so great as that during 1912 and 1913, the difference will not be very marked, for the internal-combustion engine has shown itself to be essential in practically every sphere of power employment, and moreover, the field of application is widening to a considerable extent every year.

CONCRETE LAID IN PANAMA CANAL.

The amounts of concrete laid in the major features of the Panama Canal and its auxiliary works to March 1st, 1914, are as follows:—

Gatun Locks	2,068,424	cu. yds.
Miraflores Locks	1,506,563	" "
Pedro Miguel Lock and Dam	929,232	" "
Gatun Dam and Spillway	232,256	" "
Miraflores Dam and Spillway	79,004	" "
Pedro Miguel-Miraflores duct line	6,193	" "
Central Division	1,271	" "
Balboa terminals	69,006	" "
Cristobal terminals	63,785	" "
Hydro-electric station	14,323	" "
Transmission line	6,030	" "
Aids to navigation	*5,000	" "
Relocated Panama railroad	63,123	" "
Permanent buildings, Balboa	7,202	" "
Total	5,053,311	" "

*Approximate.

Including the work on fortifications, the pontoon barge piers at Paraiso, Quartermaster's construction, municipal engineering, etc., the total concrete placed by the Canal forces is well above 5,000,000 cubic yards.

WATER POWER DEVELOPMENT IN SPAIN.

It is stated that the successful competitor for the privilege of undertaking the development of water power in the Department of Calabria authorized by an Act of the late Italian Parliament is La Società delle forze idrauliche della Sila, composed of La Banca Commerciale, Le Ferrovie Meridionali, la Società Meridionale di Elettricità, and La Société Franco-Suisse of Geneva. Inasmuch as there are few industries in the region to be developed, the work at present in contemplation is for the construction of a single electric plant, developing 50,000 horse-power; the capital necessary for this first undertaking is estimated at $8,000,000 to $10,000,000, and will be furnished by the four societies named. The dykes to be constructed in carrying out the undertaking outlined will also serve the double purpose of regulating the flow of water from the mountains, protecting the plain region from drought and from destructive inundations.

NEW EQUIPMENT IN HAMILTON, ONT., PUMPING STATION.

THE high level pumping station on Ferguson Avenue, Hamilton, is now equipped with electrically driven turbine pumps replacing the former steam plant. This station supplies water to two separate levels, making it necessary to install two different sets of pumps and each set was duplicated in order to make it sure that at least one set would always be available.

In Fig. 1 the two pumps in the foreground are Special No. 4, two-stage, Mather & Platt patent, high lift turbine pumps; each capable of delivering one million Imperial gallons per 24 hours against a total head from all causes of 131 feet. These pumps are direct-connected by flexible belt-laced couplings to 40 k.v.a. C.G.E. synchronous motors with direct connected exciters. On test at the factory, a pump efficiency of 79% was obtained, which is remarkably good for this size of pump.

The pumps for the higher level are shown in the background of Fig. 1. They are two Standard No. 5 Four-stage Mather & Platt patent high lift turbine pumps; each capable of delivering one million Imperial gallons per 24 hours against a total head from all causes of 326 feet. These pumps were connected by flexible belt-laced couplings to two 100 k.v.a. C.G.E. synchronous motors with two direct connected exciters. These pumps were guaranteed to have an efficiency of 70% and actually gave 72% on the official test.

The switchboard shown in Fig. 2 was manufactured by the Canadian General Electric Company and consists of five natural black slate panels of the central station type, equipped with horizontal edgewise instruments and K-3 oil switches, each of which is tripped automatically through an inverse time limit overload relay. One panel is provided for the control of each synchronous motor and the centre panel controls duplicate incoming lines. A voltmeter is mounted on a swinging bracket at the end of the board and is arranged to read bus voltage on all three phases.

The line panel contains one oil switch for each of the two lines and a single set of meters consisting of: 3 ammeters, 1 polyphase indicating wattmeter, 1 polyphase curve drawing wattmeter, 1 polyphase watthour meter.

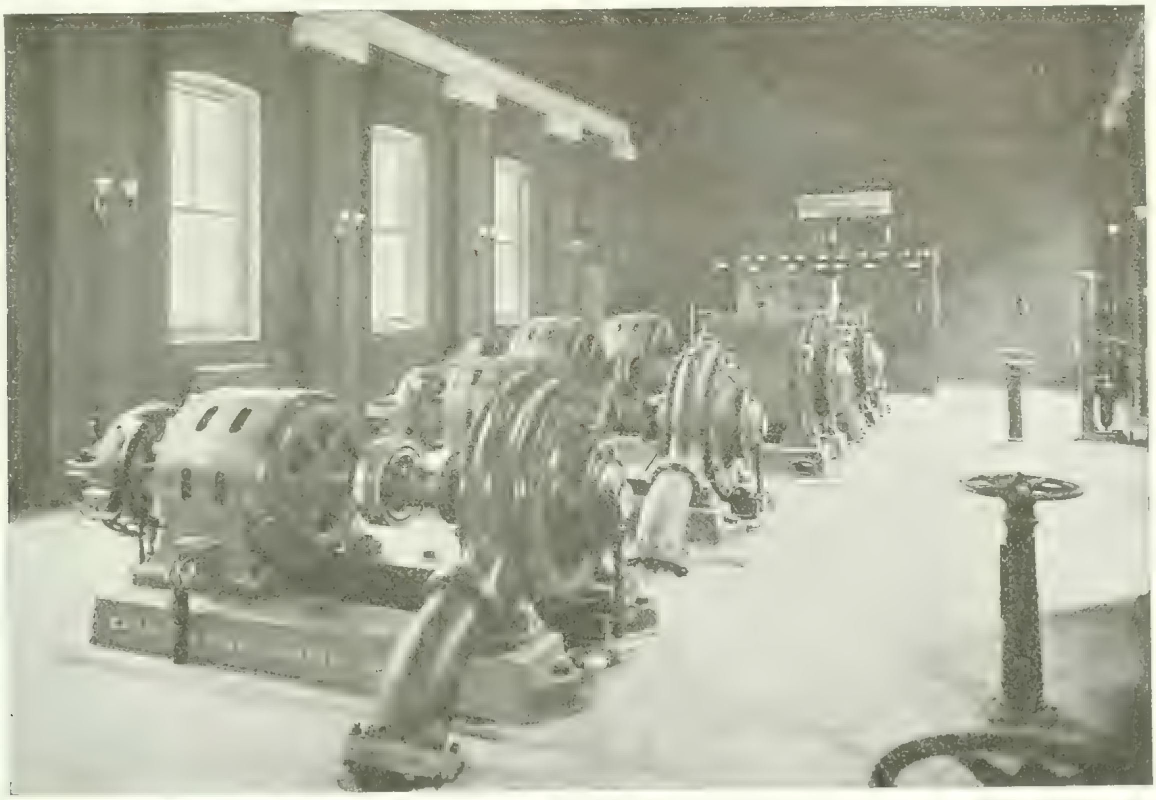


Fig. 1.—Ferguson Avenue Pumping Station, Hamilton, Ont.

Fig. 2.—Switchboard Arrangement.

Each synchronous motor panel is equipped as follows: 1 polyphase indicating wattmeter, 1 power factor indicator, 1 field ammeter, 1 rheostat mechanism, 1 D.P.D.T. field switch connected so as to excite the motor field either from a direct connected exciter or from a common exciter bus, 1 overload relay, 1 automatic oil switch, 1 starting compensator, 2 current transformers.

Starting arrangements for the motors are worked out in an unusual but very convenient way. Standard compensators are mounted on the wall back of the switchboard and are connected by bell cranks and operating rods to operating handles on the front of the panels, this mechanism being almost identical with the standard remote control oil switch mechanism. This arrangement, together with the busses, wiring, etc., is shown very clearly in Fig. 2, from which it will also be noted that, contrary to a very common practice, ample room has been allowed for the switchboard equipment.

UNPUTRESCIBLE WOOD.

ENGINEERS and others are annoyed by the rotting of railway sleepers, of piles, and of wood used to support galleries and in the building of ships, etc. Engineers, chemists, physicists, biologists, doctors, who for the construction of diverse apparatus, may need a wood possessing a maximum resistance to the causes of destruction, particularly humidity, are interested in this important question of the unputrescibility of wood. The ideal would be to find a wood able to resist putrefaction naturally. It appears from recent researches outlined in the Scientific American Supplement that the wood of the mangrove tree may be considered as absolutely unputrescible. Numerous samples of mangrove wood sent from French Guiana were, in 1909, placed at Collonges in a soaking pit in the depot of sleepers of the Paris-Lyons-Mediterranean Railway Company. These samples were surrounded with all the elements capable of producing the decomposition and rotting of the wood in the minimum of time. In spite of this the samples still remain in an excellent condition and show no signs of alteration. Why has the mangrove resisted decomposition and whence the particular and excellent qualities of this too little known wood? The grain of the mangrove is very close; hence it opposes a barrier to the invasion of water. The density of mangrove is about 110, that of oak is 70, and that of fir is 40. Moreover, mangrove wood has an amount of tannin quite sufficient to prevent the attack of insects and the multiplication of germs, damp, mould, and all the various micro-organisms which constitute the flora of the woods of different climates. The wood of the mangrove is marvellously resistant to flexion; its resistance is double that of oak, quadruple that of fir; nevertheless it is not at all brittle. To crushing, either at the end or across the fibres, it offers a resistance double that of oak and three times that of fir. It resists all attempts at twisting far better than either oak or fir, and is superior to them in suppleness. It is easily worked, and is as easily sawn as oak. It may, therefore, be concluded that mangrove wood merits employment on a large scale for numerous and varied purposes. It might be used for posts of electric lines on account of its unputrescibility, its resistance, and its suppleness. It is valuable for sleepers of narrow railways for its resistance to putrefaction and to crushing. It could be advantageously used for the special woodwork of mines.

ROAD ADMINISTRATION IN MANITOBA.

CONCERNING road administration in the province of Manitoba, Mr. A. McGillivray, Provincial Highway Commissioner, has the following to say in "The Manitoba Engineer," an annual publication of the Engineering Society of the University of Manitoba.

The construction of a system of highways suitable for the requirements of a province such as Manitoba is an expensive undertaking, nevertheless, there is no other expenditure of public moneys which will return more valuable and beneficial results than that used for the purpose of building good roads. In a province such as this, where agriculture is the predominant pursuit in the rural districts, good roads are essential to the development of all interests concerned. Not only is this true from a financial point of view, but also from a social viewpoint, as the isolation of the farm life is eliminated to a large extent by the introduction into a community of a system of well-built roads.

The administration of the road work in Manitoba, both with regard to construction and maintenance, is, primarily, entirely within the jurisdiction of the councils of the different municipalities of the province, each council having complete charge of all expenditures for this purpose within the limits of its own municipality. The assumption of this important duty by the municipalities should, and no doubt does, create a more general interest being taken in the whole question by the people, than if all the work of the province were centralized under one organization. The road to the market, although public property, may be rightfully considered an adjunct of the farm, and the thrift and prosperity of the residents of the district are largely reflected in the standard of roads obtaining through such community.

Funds for road improvements may be procured by a direct tax on the assessed valuation of rateable property in a municipality, imposed annually by the council thereof. Many municipalities in addition to the money tax, make use of the "Statute Labor Law," which gives a council the authority of imposing upon every person upon the assessment roll, the liability of one day's labor if assessed for a sum not exceeding $200; two days if assessed for a sum exceeding $200 and not exceeding $500; and one day for every additional $500 or fraction thereof. It is also the prerogative of any council to pass a by-law either permitting the labor to be actually performed on the roads within the "road beat" in which the party assessed is located, or to levy a money tax not exceeding $2 for every day of statute labor assessed.

The government of the province exercises no authority over the expenditure of municipal funds except where these funds are supplemented by a government grant. In such cases the work is performed according to plans and specifications of the Department of Public Works, supervised by an engineer of the department.

It is generally conceded that an up-to-date system of roads cannot be established in a growing province by municipal effort alone. The "Good Roads Act" now on the statutes of the province, provides for systematic aid to rural municipalities in building a system of municipal main or market roads and also in establishing a system of through highways from east to west and north to south across the province.

It rests entirely with the municipality to take the initiative in securing this government assistance. A map of the municipality showing thereon the roads or system of roads which the council desire to bring under the

operations of the "Act" is forwarded to the highways department by the municipal council.

The highways department consists of a board of three commissioners, appointed by the Lieutenant-Governor-in-Council, whose duty is to assist the municipal council in formulating schemes of highway construction under the provisions of the "Good Roads Act"; to compile statistics and collect information relative to the mileage, character and condition of the roads in the several municipalities of the province; to investigate the various methods of construction best adapted to the various sections of the province and establish standards for the construction and maintenance of highways in various sections, taking into consideration the natural conditions, character and availability of road building materials and the ability of municipalities to build and maintain roads constructed under the provisions of the "Good Roads Act."

On receipt of a plan of road improvements from a municipal council, an engineer of the department is sent into the municipality to make investigation and surveys preparatory to formulating the scheme proposed by the council and to estimate on the probable cost of carrying such scheme to completion. On the approval of any such scheme by the board and their decision being ratified by the Lieutenant-Governor-in-Council, the municipal council may pass the necessary by-laws putting the scheme into effect. Provisions are made in the "Act" for the issuing of debentures to cover the municipality's share of the cost of the work, the government agreeing to guarantee the debentures of the municipality.

The work is usually done by contract. The municipality advertises for tenders and lets the work on the advice of the highway board to the most acceptable bidder. All engineering services are supplied by the provincial government free of charge, and the work is carried through according to plans and specifications and under the directions of the department engineers.

Payments to contractors or otherwise in connection with the work is made by the municipality, the government remitting their share of expenditures made by the municipality on receipt of certified statements and declaration of the treasurer of the municipality that the amounts in question have been paid by him for work on the highways included in the scheme of improvements.

According to the provisions of the "Act," the provincial government may assist a municipality as follows:

(1) Two-thirds of the cost of the work for construction or improvement on a road which, in the opinion of the board, shall form a portion of the main highway across the province. The work done on these highways must be of a superior standard to an earth road, such as gravel, macadam or other pavement. All bridges and culverts must be of a permanent character, as concrete or steel on concrete foundations.

(2) One-half the cost of all work done on a system of roads within a municipality of a superior type to the earth road (such as gravel, macadam or other improved type of pavement) considered by the board and approved by the Lieutenant-Governor-in-Council as forming a system of main or market roads within such municipality.

(3) One-third the cost of all work done on a system of roads as mentioned in the foregoing paragraph, but where the type of road constructed is the ordinary earth grade and the bridges of such construction as timber or other material which cannot be considered of a permanent character. A municipality, however, may construct permanent culverts and bridges under this section and receive the full assistance of one-half the cost if they so desire.

The maintenance of all roads constructed under the provisions of the "Good Roads Act" is incumbent on the municipality and the provincial government has power to do any work of this character and levy on the municipality for the cost of same, where such a municipality neglects to perform the work required in keeping the roads in a state of good repair.

VANCOUVER TERMINAL IMPROVEMENTS OF THE CANADIAN PACIFIC RAILWAY.

Canadian Pacific Railway Company terminal improvements at Vancouver, B.C., are rapidly nearing completion. The general scheme embraces a passenger station and office building located on land immediately east of the present passenger station. Another dock 200 x 490 ft. has been built. A particular point of interest in this work was the use of piles 135 ft. long on the pier end. The main entrance to the station is located on Cordova Street with the main waiting room on the street level. Tracks are located about 25 ft. below this level and there is provision for four passenger tracks separated by wide platforms. Stairways and lift connect the two levels of the station and a separate foot-bridge is carried over the passenger tracks and directly connected with the waiting room at one end and with the stairways leading to the track level, thus giving access to the platforms without crossing the tracks at grade.

In order to avoid a grade crossing and the consequent delays to traffic between the city and the piers a steel viaduct is being built on the line of Granville and Burrard streets, passing over the tracks to the piers. An incline is also being built on the west side of the Granville Street viaduct to the wharf, thus giving access to the lower deck of the pier and freight sheds and to the water front.

The passenger station is a combination stone and brick structure with a steel frame. The station is divided into two principal levels on the lower of which are the baggage, mail and express rooms while on the upper are the ticket offices and waiting rooms. Above the public rooms in the station the space will be devoted to the general offices of the railroad company. The interior arrangement of the office space will be on the unit system and each unit will have complete heating and lighting facilities with partitions that may be readily installed or removed as changes in the arrangement of office accommodations become necessary.

The principal problem was to provide easy and economical communication between the city, the railroad station and the piers, these last introducing an element which is unusual in most railroad terminals so far as passenger traffic is concerned.

It is expected that the station will be ready for occupancy during the summer and that the steamship station facilities will be available somewhat earlier, although, due to the necessity of removing the old station before the viaduct can be built on the extension of Granville Street, the use of the present grade crossing over the freight yard tracks will have to be maintained for a month or two longer.

Messrs. Barrott, Blackader & Webster, of Montreal, are the architects for this work. Westinghouse, Church, Kerr & Co., of Montreal, are the engineers for the complete design, construction and equipment of the terminal, working in co-operation with the officials of the Canadian Pacific Railway.

Coast to Coast

Winnipeg, Man.—The Talbot avenue sewer at Winnipeg has been completed at a cost of $19,259.17.

Brantford, Ont.—It is stated that the T.H. and B. Railway will increase its yard accommodation in Brantford in the near future.

Sydney, N.S.—The Sydney board of trade is opposing the passing by the legislature of Nova Scotia of the Nova Scotia Tramway and Power bill.

Port Arthur, Ont.—Of the supplementary expenditure granted for roads in Ontario, $16,700 has been allotted for roads in the Port Arthur district.

Vancouver, B.C.—Overtures for a joint water supply have been made to the civic waterworks committee of Vancouver by a deputation from the South Vancouver municipal council.

Medicine Hat, Alta.—A scheme for street lighting at Medicine Hat at a cost from $35,000 to $50,000 is being advocated by the civic lighting committee and supported by the mayor.

Toronto, Ont.—The supplementary grants of the provincial government include $433,950 for expenditure on colonization roads, and $75,000 for the disposal of the Highways Commission.

Winnipeg, Man.—Several months ago, a new industry for the purification of sewage, was installed at Winnipeg at a cost of $40,000. It is now in full operation, and is stated to have given splendid results.

Montreal, Que.—The electrification of its terminals and the addition of two tracks to the present tracks feeding Windsor Street station at a cost of $1,000,000 are among the plans the C.P.R. is considering.

Fredericton, N.B.—It is understood that an arrangement has been completed whereby the Federal Government agrees to build the big bridges over the St. John and Kennebecasis Rivers on the St. John Valley railway.

Toronto, Ont.—York township council was defeated in its effort to gain powers from the legislature to force the city of Toronto to supply the township with city water by the decision of the private bills committee of the legislature.

Ottawa, Ont.—A deputation from Peterboro district will shortly interview the Government at Ottawa to present to the Government a petition asking that attention be given to the conservation of water power in the Trent district.

Transcona, Man.—It has been announced from headquarters that on May 1st the new C.P.R. yards in North Transcona, the second largest individual railway yards in the world, with 105 miles of trackage available, will be formally opened.

Toronto, Ont.—In a recent address on "City Planning" at the City Development Exhibition, Mr. J. P. Hynes advocated the advisability of inaugurating a steam railway service to give adequate transportation facilities to residents in the suburban districts of the city.

Winnipeg, Man.—It is stated that the public works department of the Dominion Government will commence work upon the docks and river front improvements at Winnipeg as soon as the river is free of ice. Preliminary expenditures are estimated at $25,000.

Halifax, N.S.—Plans and a report are being prepared by the city engineer to show in detail the watershed owned by the city and the area that should be acquired in order to secure a water supply beyond contamination. These are to be submitted to the board of control and then to the city council for approval.

Toronto, Ont.—It was reported at Toronto that Mr. David McColl, first vice-president of the C.P.R. has stated that eventually all the north shore line to Winnipeg is to be double-tracked, and that part will be double-tracked shortly; also that finally the Transcontinental from North Bay to Winnipeg will all be double-tracked.

New Liskeard, Ont.—Engineer Fullerton has handed in a report to the town council, with reference to the proposed new reservoir. He recommends the building of a circular wall of concrete, 16 feet deep, 50½ feet in diameter, which will be capable of holding 200,000 gallons of water. He further advises that a concrete wall, 6 feet in height be built above the wall of the reservoir, instead of a roof. No plans have as yet been prepared.

Ottawa, Ont.—The new Government-owned international storage elevator to be built at Calgary, for which tenders are now being called, is modelled after the two elevators now being erected by the Government at Moose Jaw and Saskatoon. It will have a capacity of 2,500,000 bushels, but will be built so that its capacity can be easily increased, if necessary. It will be thoroughly modern in every way and will be fitted with every variety of cleaning apparatus for grain.

Winnipeg, Man.—The statement of the civic light and power department at Winnipeg for the month of March, shows that the net cash receipts of the month, for current year only, reached a total of $83,046.59, an increase over the same period last year of nearly $25,000, or about 40 per cent.; the figures for March of last year being $58,358.04. The realizable earnings of the department for last month were $76,969, as compared with $55,637 for March of last year, an increase of $21,332, or about 40 per cent.

Montreal, Que.—It is reported from Montreal that construction work will likely be begun this year on the C.N.R.'s western line from Oliver to St. Paul de Metis, which is guaranteed by the Saskatchewan Government for 100 miles at $13,000 per mile. The work of cutting the right of way has been continued throughout the winter, and is now practically completed. About 15 miles of grading have been done. The line will run northward close to Battenberg, Egremont, Radway Centre, Clodford and south of Smoky Lane.

Oil Springs, Ont.—Nine drills have already been employed at Oil Springs since the flow of gas was struck on the Fairbanks farm, while arrangements have been made by the Union Gas Company for piping gas to Petrolea, and a number of carloads of 6-inch pipe have been unloaded. The gusher has had to be capped and will remain so until a system of regulators has been installed, which will reduce the flow and pressure to a degree that will be compatible with the staying qualities of ordinary gas pipes and the boiler furnaces.

Steelton, Ont.—It has been reported recently from Sault Ste. Marie, Ont., that artesian wells have been discovered in the western portion of Steelton. It is stated that two-and-a-half inch pipes have been driven down to a depth of 78 feet, and are now supplying a gush of water estimated to measure 350 gallons a minute; while the town's present consumption is 160 gallons per minute. It is expected there will be no need of chlorination of the water; and it is considered likely that the town will erect a pumping station and standpipe to control the supply.

Montreal, Que.—The installation of an elaborate interlocking switch system has been completed by the C.P.R. at the Windsor station in Montreal. All signals, levers, and

machinery are interlocking. The system is operated by one individual at an illuminated diagram, consisting of 88 levers and showing the whole of the yard trackage—11 tracks in all—with the positions of the several trains. Each lever not only places a train upon its proper track, but also effects certain positions with respect to other movements in the yards. There is no isolated action, each portion of the machine or diagram is inter-relative.

Fredericton, N.B.—It is announced at Fredericton that the construction of a dam across the St. John River at Meductic is proposed by the St. John River Hydro-Electric Company. The project has been laid before the Legislature, and its promoters claim the work will cause an ultimate expenditure of some $3,650,000. The proposed dam will cross the St. John at Meductic above Fredericton, and transmit power to Fredericton and Maryville, down the river valley, over 80 miles to St. John. The New Brunswick Hydro-Electric Company, however, opposes this plan, and having last year obtained legislation, now proposes to develop electric power from streams and lakes in St. John and Charlotte counties, with transmission to St. John for light and power purposes, including power for street railways.

Montreal, Que.—The work on the Glen bridge of the C.P.R. at Westmount will be completed this week. The new structure will double the capacity of the old one, allowing for 4 tracks where the former structure over the highway carried 2 tracks. The rebuilding of this bridge is part of the general plan for the construction of 4 tracks on the Island of Montreal between Windsor Station and the bridge at St. Annes, construction planned for and forming part of the provision for the future traffic out of the enlarged station. While the enlarged trackage will not be completed immediately, it forms part of the general plan of the terminal improvements of the Canadian Pacific in Montreal.

Ottawa, Ont.—At an early date, the Department of Naval Service will issue a publication of the results of the hydrographical surveys conducted throughout the summer under its auspices. It is stated that the report will show that a first-class harbor can be developed in the Nottaway River estuary at the southern extremity of James Bay, or the terminal gulf of Hudson Bay. Good shelter, ample room and a sufficient depth of water have been found, and there is little silt in evidence. It is believed that this intelligence will stimulate the Province of Quebec to accelerate the construction of a railway from the Nottaway River mouth to connect James Bay with Montreal and Quebec, thus providing an alternative to the marine outlet from Hudson Bay through the Straits when ice conditions in the North rendered the latter route dangerous.

Saskatoon, Sask.—The Saskatchewan Local Government Board has authorized Saskatoon debentures to the amount of $489,307, to be expended as follows: sewer mains, $7,374.35; water mains, $6,916.99; storms sewers, $19,463.46; street railway extensions, $25,000; electric light and power plant, $200,000; pumping plant extension, $10,000; sidewalks, $3,590; pavements, $19,912.32; paving approach to traffic bridge, $3,600; additional expenditure on new power house, land and buildings, $15,000; additional expenditure on police patrol and fire alarm system, $10,000; additional expenditure on exhibition biuldings, $10,000; additional expenditure on power house machinery, $85,000; waterworks meters, $25,000; water mains, $950.36; additional expenditure on intercepting sewer, $12,500; additional expenditure on force water main, $27,000; additional expenditure on sedimentation basin, $8,[illegible]

Toronto, Ont.—Plans and specifications have been completed, after several months' preparation, for the proposed North Toronto sewer system, and are now being considered by the city authorities. The estimate for the system which has been planned has been fixed at $4,144,256; and the scheme provides for the construction of two storm sewers, in addition to the regular sewers, one through the Waterworks Park, the other from Bayview Avenue to the Don River, to the proposed location of the new sewage disposal plant. The plant will consist of a standby tank for treatment of storm water, detritus tanks, Imhoff tanks, chlorinating device, sludge-drying beds, and sprinkling filters. While the purchase of sufficient land is recommended to make provision for the construction of a sewage-disposal plant capable of treating the sewage from the watersheds tributary to this system, the plant will be constructed for present requirements. Other units may be added as development demands. The total estimated cost of the plant for present requirements, including the site for future developments, is $305,900.

Victoria, B.C.—A recent report upon the work in connection with the Sooke Lake waterworks supply states that, between Cooper's Cove and Humpback reservoir, the track laying is being advanced rapidly, and the bad portion of the excavation on the pipe line near the reservoir is almost covered. A considerable amount of work remains to be done by the city at the reservoir in the shape of completing the main dam, erecting the gate house, constructing the two core dams and other work. Within two or three months this work will be completed, and from that time on the contractors for the concrete flow line and the steel riveted pressure line will proceed with their sections of the work. When the line is completed, 34 concrete trestles will have been erected between the lake and Humpback reservoir. Of these, 14 have been completed, while the concrete is being poured into the forms for the balance. Also, the steel bridge across the Sooke River is in place. The contract with the Burrard Engineering Company of Vancouver, to which was let the contract for the fabricating and laying of the steel pressure pipe line from Humpback reservoir to the city is now being prepared by the city solicitor and will be ready for signature after it has been approved by the city.

Victoria, B.C.—Constructions of the first magnitude which are progressing under the Public Works Department of the British Columbia Government, include the Court House at Prince Rupert, upon which initial work is already well advanced. The site is being levelled and a subway is now under construction. Mr. J. Cox, the local architect, has the plans for the building well in hand, and tenders will be called for very shortly. The estimated first cost of the building is between $300,000 and $400,000, but the plans are so drawn that it will be possible to make additions from time to time as circumstances warrant. The Pitt River bridge is another big undertaking. Already some important preliminary work has been done in the way of making soundings and borings. The Government has purchased the necessary steel from the C.P.R. which was used in the old bridge. The cost of this important public work will approximate $500,000. The Government office at Duncan, plans for which are in the hands of Mr. Coates, the local architect, will call for an expenditure of $40,000. The completion of the two new transcontinental railways has warranted provision by the Provincial Government in [illegible] and this year $144,000 will be expended on buildings in Cariboo and $216,000 in Skeena. Public works and buildings already in progress [illegible] ceed this year are the addition to the parliament buildings at Victoria [illegible] Burnaby, and court houses at Vernon, Nicola and Merritt.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page ?? a directory of such societies and their chief officials.

CANADIAN SOCIETY OF CIVIL ENGINEERS—TORONTO BRANCH.

The luncheon held on Thursday last by the members of the Toronto branch, Canadian Society of Civil Engineers, was attended by over 100. The speaker was Mr. J. R. W. Ambrose, newly-appointed chief engineer of the Toronto Terminal Company, to take charge of the construction of the new union station and railway viaduct. Mr. Ambrose did not enter upon any technical discussion of the project, but interested his hearers by briefly summarizing the advantageous factors maintained for the young engineer by railway work.

The branch is holding a meeting to-night (Thursday) to be addressed by Mr. J. Keele of the Geological Survey of Canada. Mr. Keele's extensive knowledge of Canadian clays is an assurance that his subject, "The Clays and Clay Industries of Canada," will be authoritative and appropriately treated. In its December 11th, 1913, issue, *The Canadian Engineer* published an article written by him on Field Examination and Testing of Clays, while synopses of his report to the Dominion Government on the pre-heating of clays and also sewer pipe and roofing the tests of Western Canada clays, appeared in the issues of February 12th and 19th respectively.

THE WELLAND SHIP CANAL.

On April 16th, J. L. Weller, C.E., Chief Engineer of the Welland Ship Canal, addressed a meeting of the University of Toronto Engineering Alumni Association, on the design and construction of the present project, which is the third to bear the name of "Welland Canal." Mr. Weller, to whom must be accredited practically the entire scheme and design, illustrated his paper by numerous slides descriptive of it and others including the Panama and the Sault Ste. Marie Canals.

In the course of his remarks Mr. Weller outlined a single-lock proposal instead of the seven locks decided upon. A single lock, he stated, would have been conducive to a great saving of time and money and would have been a quite safe proposition, but for the reason that the rock in that vicinity was not of a nature to carry the mammoth construction necessary.

At present work is well under way on the construction of the $50,000,000 project and, according to Mr. Weller's expectations, it will be completed in 4 years' time.

The Engineering Alumni Association had extended an invitation to be present to the members of the Toronto branch of the Canadian Society of Civil Engineers, many of whom responded by being present.

COMMISSION'S NEW HEADQUARTERS.

The Quebec Streams Commission has recently moved its offices in Montreal from 130 St. James Street, Yorkshire Building, to Room 803, McGill Building.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Diven, 47 State Street, Troy, N.Y.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9-13, 1914. J. E. Pennybacker, Secretary, Colorado Building, Washington, D.C.

AMERICAN PEAT SOCIETY.—Eighth Annual Meeting will be held in Duluth, Minn., on August 20, 21 and 22, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

INTERNATIONAL CONFERENCE ON CITY PLANNING to be held in Toronto, May 25-6-7, 1914, in charge of the Commission of Conservation. Secretary, James White, Ottawa.

CANADIAN FORESTRY ASSOCIATION.—Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal.

PERSONALS.

JAS. C. MURTON has been appointed superintendent of the Regina branch of the National Paving and Contracting Company, Limited.

THOS. ALLISON of Toronto, and formerly road superintendent of Galt, has been appointed road superintendent for Wentworth County, Ontario.

GEO. W. LEE, Mayor of North Bay, has been appointed to a seat on the Timiskaming and Northern Ontario Railway Commission, to succeed Fred Dane, resigned.

J. C. DUFRESNE, M.Can.Soc.C.E., has resigned the position of field engineer for Messrs. Cummins and Agnew, of Vernon, B.C., in order to re-establish his private practice at Penticton, B.C.

J. H. BROWNLEE, C.E., of Vancouver, gave an address there last week on "The Future of Arctic—vs. Antarctic Exploration," in which he dealt in particular with the survey work which such exploration would include.

F. A. DALLYN, B.A.Sc., C.E., Provincial Sanitary Engineer of Ontario and GEO. HOGARTH, Assistant Engineer, Department of Public Works, Ontario, have been recently

elected to membership in the American Water Works Association.

M. H. BAKER, B.A.Sc., formerly city engineer of Prince Albert, Sask., is now engaged with the Surveys Branch Department of the Interior, on the survey of roads and townsites in the Rocky Mountains and Yoho parks, in the vicinity of Banff.

SIR WILLIAM WILLCOCKS, who designed the Assuan Dam and similar regulation and irrigation works on the Nile River, Egypt, and who is now engaged upon a project to reclaim vast areas bordering on the Tigris and Euphrates rivers, is attending the National Drainage Congress at Savannah, Ga., this week, as one of the chief speakers.

ROBT. C. MUIR, until recently with Mackenzie, Mann and Co., has joined the staff of W. A. McLean, Provincial Highways Engineer for the Ontario Department of Public Works. Mr Muir, who has contributed several articles on road making to the reading columns of *The Canadian Engineer*, had a wide and varied experience in this work in Scotland, where he has held several important and responsible positions of a similar nature.

OBITUARY.

The death was reported on April 14th of SIR WILLIAM WHYTE, formerly vice-president and a director of the Canadian Pacific Railway, vice-president of the Winnipeg Electric Railway and prominent in financial affairs in Winnipeg and Western Canada. As one of the pioneers of railroading in Canada, the career of Sir William Whyte is well known to railway engineers throughout the Dominion. He was born in Scotland in 1843 and came to Canada at the age of 20. Twenty years were then spent in the service of the Grand Trunk Railway, during which he rose from the position of brakeman to that of Assistant Superintendent of the central division, extending from Kingston to Stratford.

One year after the last spike had been driven in the main line of the C.P.R., Mr. Whyte, who had entered its service several years previously, became general superintendent, and afterwards manager of all lines west of Lake Superior. He spent 11 years as general superintendent, 4 as manager of Western lines, 3 as assistant to the president, and 6 as second vice-president, with complete charge of the company's affairs between Lake Superior and the Pacific. For 1 year prior to his retirement in 1911, he was vice-president of the company.

Cement Industry in Japan.—The first Japanese cement works were established at Tokio in 1871, and the first rotary kiln was here installed about ten years ago. The plant has been extended until the output is now about 1,000,000 barrels a year.

Following the example of Quebec lumbermen and paper manufacturers, members of both trades in Ottawa district have taken steps towards the establishment of what will be known as the Canadian Forest Protective Association, a body which will be largely along the lines of that organized some years ago in the St. Maurice Valley for the protection of limits there. A committee has been appointed to proceed with a plan of organization. This will include the appointment of a manager, under whom will be four inspectors; and these in turn will direct a staff of rangers. On all commanding positions lookouts will be established to give warning in case of fire; and telephones will be installed throughout the different limits whose owners are members of the association. The railroad lines throughout the limits will also be patrolled and by all these means it is hoped to very greatly reduce the loss from forest fire, now so great.

BULGARIAN RAILWAY, BRIDGE AND HARBOR CONSTRUCTION.

An American consular report states that it is intended that Porto Lagos shall be the main harbor for Bulgarian trade in the Ægean. A railroad is to be built from Kaskovo across the Rodopo Mountains to this port, and surveys are to be begun forthwith. The Bulgarians desire to build a bridge over the Danube at Nikopoli or at Sistova, and it is hoped that a trunk line, starting from one or the other of these points and leading in an almost due southerly direction to Porto Lagos, will provide a natural outlet for Bulgaria, Roumania, southern Russia, and western Europe. This line would follow the route Nikopoli (or Sistova), Tirnovo, Stara Zagora, Mikhaelovo, Haskovo, Mastanli, Kirjali, Narli Keui, to Porto Lagos. The cost of the new section Mikhaelovo-Haskovo is estimated at $6,000,000; the distance is 109 miles. The new line is to be built by contract in four sections, a separate bid being invited for each section. There will be two tunnels, 2,500 and 2,000 metres in length respectively. The cost of the bridge over the Danube is estimated at $3,000,000, to be shared equally between Bulgaria and Roumania. It is hoped that Porto Lagos may become a Mediterranean port of the first class; $4,000,000 will be expended, and construction will be opened with public bids. The harbor will be built somewhat east of the present town. The contracts will be allotted this spring, and it is hoped that the railroad and port will be completed in three years. When Porto Lagos will be opened to commerce Varna and Bourgas will decrease in importance. It is not improbable that a special loan will be floated to cover the above project, as favorable terms might be obtained for a productive enterprise of this nature. In regard to Dedeagatch, this port is not under the present circumstances considered of much importance, and instead of a harbor a small mole is to be constructed there to facilitate loading and unloading lighters. Dedeagatch will remain an open roadstead. It is probable that the following railway lines will be constructed in the near future in Bulgaria: Schumla to Karnovit; Radomir to Dubnitza-Dzumaga; Yamboli to Kizil Agatch.

Before reoccupation of Adrianople by the Turks an important project for canalization of the Maritsa River had been discussed. The scheme would have been costly, but it is believed that by confining the Maritsa to its natural bed a sufficient depth of water could have been obtained to enable ocean steamers to ascend the river as far as Adrianople and tugs and lighters even as far as Philippopolis. The reclamation and irrigation of the rich lands on either banks of the Maritsa would have given scope for growing tobacco, rice, and cotton on a large scale, and this would have amply compensated for the original outlay. The scheme does not appear to have been definitely abandoned, and it is possible that an agreement may yet be made with Turkey, whereby it may be carried out in a modified form.

Senor Iglesiac, a Madrid electrician, has given a successful demonstration of an apparatus, of which he is the inventor, for condensing and utilizing atmospheric electricity. With the device, Senor Iglesiac lighted and extinguished at will 15 electric bulbs placed at a distance of 600 yards. Experts expressed the opinion that the discovery has great possibilities with regard to cheap production of current for industrial purposes. Early last February, William Marconi succeeded in lighting an electric bulb at a distance of 6 miles by a wireless current supplied from a 100 horsepower engine.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21604—April 6—Authorizing C.N.R. to construct Beinfait-Estevan Branch across spur of C.P.R. in N.E. ¼ Sec. 19-2-6, W. 2 M., Sask. And rescinding Order No. 20117, dated Aug. 16th, 1913, in so far as it authorized crossing spur to Western Dominion Collieries, Limited.

21605—April 6—Authorizing C.N.R. to cross and divert road between Secs. 20 and 29-29-8, W. 4 M., Alta.; rescinding Order No. 17158, dated Aug. 1st, 1912, in so far as it authorizes crossing and diversion of said road.

21606—April 6—Authorizing G.T.R. to construct siding and spur therefrom, into premises of Lord and Barnham Co., in part lots 1 and 2, plan No. 69, Berryman plan, and part of lot 14, Con. 6, Tp. Grantham, Co. Lincoln, Ont.

21607—April 3—Amending Orders Nos. 19346 and 21197, dated respectively May 19th, 1913, and January 12th, 1914, to provide that signals at crossing of industrial spur of M.C.R.R. to premises of Postum Cereal Co. of Canada, Limited and at crossing of Essex Terminal Ry. be normally clear for Sandwich, Windsor and Amherstburg Ry. Co.; and authorizing Sandwich, Windsor and Amherstburg Ry. to operate over crossing at a speed not exceeding 10 miles an hour; when trains of Essex Terminal Ry. or M.C.R.R. proceed over crossings, trainmen operate levers as required. 2. That, by agreement between Cos. interested, rights of seniority of M.C.R.R. and Essex Terminal Ry. be not prejudiced by this Order.

21608—April 7—Approving location C.P.R. station in Lot 4, Con. 11, Tp. Hinchinbrooke, Co. Frontenac, Ont., mileage 36.74.

21609—April 6—Authorizing M. and S. Co.'s Ry. to run and operate trains and cars, with passengers, baggage, express, and other traffic, over and upon line of Central Vt. Ry. between Marieville and St. Cesaire, Que., distance of 9 miles, and to use Central Vt. Ry. Co.'s passenger and freight stations, station yards, and other facilities at and between those points.

21610—April 6—Directing that expenses of an inspector, to be appointed by C.P.R. to protect traffic at crossing of Harris St., be borne and paid by city of Vancouver, B.C., pending final decision by Board after hearing.

21611—April 6—Directing that, within 60 days from date of this Order, G.T.R. install improved type of automatic bell at crossing of County Road No. 8, village of Moorefield, Ont., and thereafter maintain bell at own expense, 20 per cent. of cost of installing bell be paid out of Ry. Grade-Crossing Fund, remainder by Railway Company.

21612—April 8—Authorizing G.T.R. and C.P.R. to operate trains over crossing in West Half Lot 14, Con. 2, Tp. Trafalgar, at mileage 32.56 from Toronto, Ont., without first being brought to a stop.

21613—April 8—Authorizing C.P.R. to construct spur for Heron Bros., Sudbury, Ont., from a point on easterly limit of right-of-way, Lake Superior Div., Sudbury Sub. Div., in Lot 11, Con. 1, Tp. Cleland, Dist. Sudbury, Ont., at mileage 111.5 of said main line, Sudbury Subdivision.

21614—April 7—Authorizing G.T.P. Ry. to construct across forty-one (41) highways in District of North Alberta, Alta., mileage 0.0 to mileage 60.4.

21615—April 7—Authorizing G.T.R. to reconstruct three (3) bridges; namely, No. 336, mileage 179.99, 6th Dist.; No 334, mileage 175.86, 6th Dist., and No. 297, mileage 62.88, 5th Dist., Province of Ontario.

[illegible]—April [illegible]—Approving [illegible] and authorizing clearances as shown on plan of Standard House for track scales, subject to certain conditions. (Can. Nor. Que. Ry. Co. plan).

[illegible]—April 8—Authorizing C.N.R. to operate trains, for construction purposes only, for period of 3 months from date of this Order, over crossing of C.P.R. in Lot 101, Parish of St. Paul, Man.; provided operation be limited to hours of between 6 and 7 a.m., 12 and 1 noon, and 6 and 7 p.m.

21618—April 7—Authorizing T.H. & B. Ry. to construct spur in city of Hamilton, Ont., into lands of the Gillies Guy Coal Co., Limited, subject to and upon certain conditions.

21619—April 7—Authorizing Cedars Rapids Mfg. and Power Co., of Montreal, to take, for purpose of right-of-way of its transmission line, additional land across Lots 13 and 10, Parish of St. Joseph de Soulanges, Co. Soulanges, Que., property of Polycarpe Cholette.

21620—April 8—Granting leave to Montreal Light, Heat and Power Co., to lay 30-in. gas pipe across swamp presently under lease by G.T.R. from Dept. Ry. and Canals, Cadastral Nos. 1005, 1026, 1025, Parish of Lachine, near western end of G.T.R., Turcot Yards.

21621—April 9—Suspending, pending investigation by Board, increased rates on lumber shown in Supplement No. 51 to G.T.R. Tariff C.R.C. No. E-2318; C.P.R. Tariff C.R.C. No. E-2779; and C.N.R. Tariff C.R.C. No. E-419.

21622—April 9—Approving revised location Esquimalt and Nanaimo Ry., between mileage 71 and 76.6, Vancouver Island, B.C.; 2. Ry. Co. is authorized to divert Government Wagon Road in Lot 66, from present location at Station 3657.43 to Station 3654.8; to carry highway underneath railway at point of crossing.

21623—April 9—Authorizing Winnipeg Electric Ry. to cross, at grade, with its tracks, on Pembina Highway, spur of C.N.R. running to premises of Arctic Ice Co., and the Agricultural College, Municipality of Fort Garry, Man.

21624—April 8—Approving location C.N.O.R. station grounds at National Park, Tp. Boyd, Dist. Nipissing, Ont., at mileage 170 from Ottawa.

21625—April 9—Authorizing C.P.R. to reconstruct bridge No. 86.5, Sherbrooke Subdivision, over Magog River.

21626—April 14—Approving certain deviations and location of the Glengarry and Stormont Ry., namely,—from a connection with main line Ont. and Que. Ry., C.P.R. Lessees, in Lot 418, Parish St. Polycarpe, Que., southwesterly to point on east side River Beaudet, Lot 8, Con. 5, Tp. Lancaster, Co. Glengarry, Ont., about 1,255.5 ft. west of Interprovincial Boundary, mileage 0 to 4.96; and 2, from a point in Lot 10, Con. 2, Tp. Charlottenburg, mileage 15.04, to point on north side Ninth St., town of Cornwall, Ont., mileage 27.

21627—April 14—Amending Order No. 21559, dated March 27th, 1914, by adding clause to provide that Order be without prejudice to right of C.N.R. to construct permanent work at point in question at any time, on due notice being given to C.L.O. and W. Ry.

21628—April 11—Establishing collection and delivery limits of Dominion Express Co., in city of Lethbridge, Alta., and rescinding Order No. 21088, dated December 23rd, 1913.

21629—April 11—Extending collection and delivery limits of express companies in city of Regina, Sask.; and rescinding Order No. 14906, dated September 14th, 1911.

21630—April 9—Authorizing T.H. and B. Ry. to construct spur, in Twp. Ancaster, extending from a point on Co.'s main line across Lot 37, Con. 1, Tp. Ancaster, and running south-westerly through lands of M. J. Ireland, and across highway in said Twp., thence through lands of Mineral Springs Sand and Gravel Co., Limited, in Lot 36, said Concession, subject to certain conditions.

21631—April 11—Authorizing G.N.R., to operate trains over crossing of C.P.R. at mileage 1.4, Lot 1899, East Kootenay Dist., B.C., without first being brought to a stop; and that C.P.R. is authorized to operate over said crossing in accordance with provisions of Order No. 15941.

A weekly paper for engineers and engineering-contractors

ANALYSIS OF STATICALLY INDETERMINATE FLAT ARCHES

STUDIES OF THE TWO-HINGED ARCH AND ARCH WITHOUT HINGES—A UNIFORMLY DISTRIBUTED LIVE LOAD ASSUMED OVER PARABOLIC STRUCTURE.

By V. J. ELMONT, B.Sc., A.M. Can. Soc. C.E.

IT is assumed in this paper that the arches possess a vertical axis of symmetry, have a rise less than 1/7 to 1/8 of the span, and that the supports are at the same height. Further, the computation is based on the assumption that the live load can be considered as uniformly distributed as for passenger bridges, floors, roofs and similar structures; that the arch takes the form of a parabola, and that the moments of inertia do not vary significantly.

The results arrived at are also applicable to circular arches with sufficient accuracy, while for arches with considerable differences in the cross-section at various points the general formulæ for statically indeterminate structures must be applied. The formulae given here will, however, for this case, as a rule, serve as a useful guide for the determination of trial dimensions.

The types which will be considered are: (1) the arch with two hinges at the springing lines, and (2) the arch

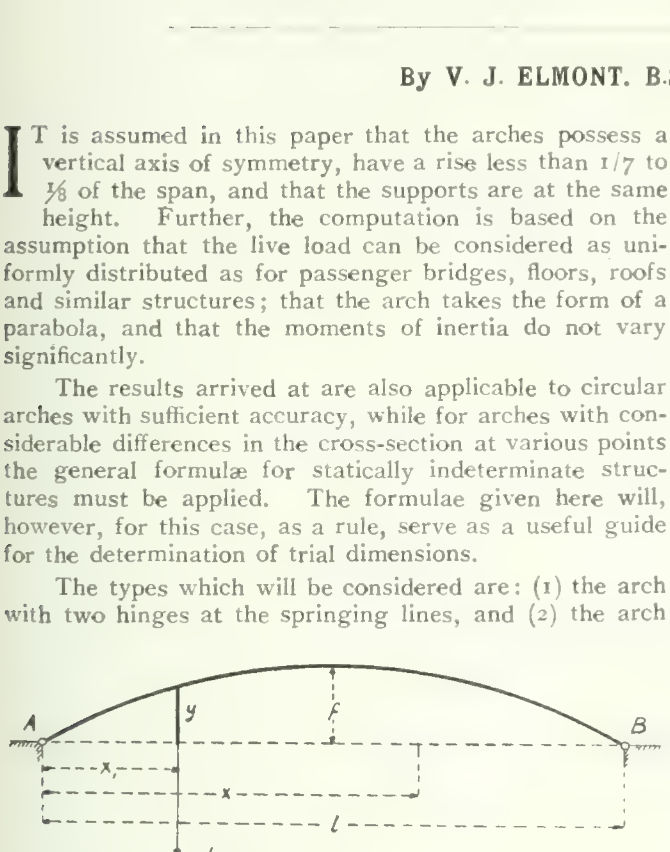

Fig. 1.

without hinges. The method followed in their analysis is the one developed by Professors Müller-Breslau and Ostenfeld.

The Two-Hinged Arch.—This arch has one statically indeterminate quantity and as such is chosen the horizontal pressure. The vertical components of the reactions are directly determinable by the statical equations and therefore not influenced by the dimensions of the cross-section of the arch nor by a slight yielding of the supports.

The equation of the line of influence of the horizontal pressure is $X = \dfrac{\delta_{ma}}{\delta_{aa}}$; δ_{ma} being the deflections of the various points, m, of the centre line of the arch, caused by a horizontal pressure of unity acting as sole load on the statically determinate auxiliary system. This system is, on account of the choice of the statically indeterminate quantity already referred to, a curved beam with one fixed and one roller end. δ_{aa} is the movement of the roller end produced by the same load.

From the general theory for statically indeterminate structures it is known that the deflections δ_{ma} can be determined as bending moments occasioned by the so-called "v" forces, acting on a simply supported beam with the same span as the arch; taking into account the assumptions mentioned in the introduction the "v" forces will be

$$v = y dx,$$

where y is the ordinate to the centre line of the arch, measured from the line between the hinges. The values of y corresponding to the various abscissæ x are given by the equation of the parabola which forms the centre line of the arch,

$$y = \frac{4f}{l^2} \times (l - x),$$

f being the rise of the arch, l the span, and x the abscissa measured from a hinge. When these "v" forces act on a simply supported beam, they will produce reactions which are equal to half the area between the arch and the line connecting the hinges, or $\frac{1}{3} fl$; whence the bending moment ($= \delta_{ma}$) at the point with the abscissa x

$$\delta_{ma} = \tfrac{1}{3} flx - \int_0^x y dx_1 (x - x_1) \text{ (see Fig. 1.)};$$

and by application of the equation of the parabola

$$\delta_{ma} = \tfrac{1}{3} flx \left[1 - 2\left(\frac{x}{l}\right)^2 + \left(\frac{x}{l}\right)^3\right]$$

or

$$\delta_{ma} = \tfrac{1}{3} fx (l - x) \left[1 + \frac{x}{l} - \left(\frac{x}{l}\right)^2\right].$$

The denominator δ_{aa} of the expression for the statically indeterminate quantity is

$$\delta_{aa} = \int_0^l y^2 dx + l i^2$$

where i is the constant radius of inertia.

By substituting for y

$$c_{aa} = 16\frac{f^2}{l^4}\int_0^l (lx-x^2)^2\,dx + h^2 l$$

$$\text{or,}\quad c_{aa} = \frac{8}{15}f^2 l + h^2 l = \frac{8}{15}fl\left[1 + \frac{15}{8}\left(\frac{i}{f}\right)^2\right].$$

Introducing

$$\alpha = \frac{1}{1 + \frac{15}{8}\frac{i^2}{f^2}},$$

the equation for the line of influence of the horizontal pressure will be

$$X = \frac{5}{8}\alpha\frac{x(l-x)}{fl}\left[1 + \frac{x}{l} - \left(\frac{x}{l}\right)^2\right].$$

The last factor does not vary considerably; for $x = 0$ and $x = 1$ the value is 1 and its maximum value, reached for $x = \frac{1}{2}l$, is 1.25. No great error will therefore arise by taking this factor as a constant, which again leads to the line of influence becoming a parabola. The mean

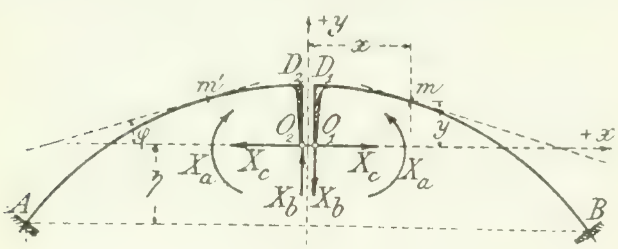

Fig. 2.

value of that factor used, is that which gives the same horizontal pressure for a uniformly distributed total load. It is calculated by either the exact equation of the approximation, whereby the equation for X attains the simple and suitable form

$$X = \frac{3}{4}\alpha\frac{x(l-x)}{lf}.$$

The line of influence of the bending moment M_m at the various points m is consequently easily derived from the general equation

$$M_m = M_{o,m} - M_{a,m}X,$$

where $M_{o,m}$ is the corresponding moment in the auxiliary system and $M_{a,m}$ is the moment produced by $X = -1$, which again is equal to the ordinate y of the point m, so that $M_m = M_{o,m} - yX$.

The equation for the line of influence of the normal pressure N_m in the arch is $N_m = -X$, on account of the assumed small rise of the arch.

By means of these lines of influence the moments and horizontal pressures for different points of the arch and varying loading conditions have been determined as follows:

For a uniformly distributed load g per unit length acting over the entire span the horizontal pressure will be

$$H = \frac{gl^2}{8f}\alpha;$$

and the bending moment at a point of the centre line of the arch at a distance x from one of the hinges and having the ordinate y,

$$M = \frac{gl^2}{8f}\cdot y(1-\alpha).$$

For $\alpha = 1$, which corresponds to the case where the shortening of the arch, due to the load on it, is so small that it can be neglected, $M = 0$ and consequently the maximum and minimum moments produced by a uniformly distributed live load have the same numerical values.

For a live load p per unit length the maximum moment at the crown of the arch is

$$\text{max. } M = \frac{1}{4}pl^2\left[\frac{1-\alpha}{2} + \alpha\left(1 - \frac{2}{3\alpha}\right)^2\right];$$

and the corresponding horizontal pressure,

$$H = \frac{pl^2}{8f}\alpha\left[1 - 2\left(1 - \frac{2}{3\alpha}\right)^2\left(1 + \frac{4}{3\alpha}\right)\right];$$

and,

$$\text{min. } M = -\frac{1}{4}pl^2\alpha\left(1 - \frac{2}{3\alpha}\right)^2;$$

with

$$H = \frac{pl^2}{8f}\cdot 2\alpha\left(1 - \frac{2}{3\alpha}\right)^2\left(1 + \frac{4}{3\alpha}\right).$$

For $\alpha = 1$,

$$\text{max. } M = +\frac{1}{108}pl^2,\quad H = \frac{13}{27}\frac{pl^2}{8f};$$

and

$$\text{min. } M = -\frac{1}{108}pl^2,\quad H = \frac{14}{27}\frac{pl^2}{8f}.$$

For $\alpha = .974$, $\left(\frac{i}{f} = .12\right)$,

$$\text{max. } M = +\frac{1}{92}pl^2,\quad H = .54\frac{pl^2}{8f};$$

$$\text{min. } M = -\frac{1}{130}pl^2,\quad H = .46\frac{pl^2}{8f}.$$

The greatest possible bending moment in the arch acts at a point, the abscissa of which lies between $x = .23\,l$ and $.25\,l$, according to the value of α.

For $\alpha = 1$, the abscissa is $x = .23\,l$, and,

$$\text{max. } M = +\frac{1}{62}pl^2,\quad H = .40\frac{pl^2}{8f};$$

and,

$$\text{min. } M = -\frac{1}{62}pl^2,\quad H = .60\frac{pl^2}{8f}.$$

For $\alpha = .974$, $x = .24\,l$ and

$$\text{max. } M = +\frac{1}{58}pl^2,\quad H = .43\frac{pl^2}{8f};$$

and,

$$\text{min. } M = -\frac{1}{67}pl^2,\quad H = .57\frac{pl^2}{8f}.$$

When one-half of the arch is loaded, between hinge and crown, the horizontal pressure is

$$H = \frac{pl^2}{16f}\alpha;$$

and the bending moment at the crown,

$$M = \frac{1}{16}pl^2(1 - \alpha).$$

The maximum and minimum moments act at the points

$$x = \frac{1}{4}l\frac{3 - 2\alpha}{2 - \alpha} \text{ and } x = \frac{1}{4}l\frac{2\alpha - 1}{\alpha},$$

and have the values.

$$\text{max. } M = -\frac{1}{64}pl^2\frac{(3 - 2\alpha)^2}{2 - \alpha},$$

$$\text{min. } M = -\frac{1}{64}pl^2\frac{(2\alpha - 1)^2}{\alpha}.$$

Thus, for $\alpha = 1$ the numerical value is $\frac{1}{64}pl^2$.

For the maximum deflection and rise at the crown Müller-Breslau has given the following approximations, the arch being loaded with live load (p per unit length) only:

$$\text{maximum deflection } \frac{pl^4}{EJ}\left[.00034 + .15\left(\frac{i}{l}\right)^2\right],$$

$$\text{maximum rise } \frac{pl^4}{EJ}\left[-.00034 + .10\left(\frac{i}{l}\right)^2\right],$$

E being the modulus of elasticity and I the moment of inertia.

The effect of the bending moments and normal forces due to an increase of the temperature of t° can readily be computed as the horizontal pressure produced by it is

$$X_t = \frac{\delta_{at}}{\delta_{aa}},$$

δ_{at} being the movement of the roller end of the auxiliary system for t° increase of temperature, δ_{at} taken positive in the same direction as δ_{aa}.

As $\delta_{at} = E J \epsilon t l$

$$X_t = EJ\frac{\epsilon t l}{\delta_{aa}} = \frac{15}{8}EJ\alpha\frac{\epsilon t}{f^2}$$

where ϵ is the elongation per unit length for one degree increase.

A yielding of the supports can be treated in a similar way; as already mentioned, it is only a movement in horizontal direction which has influence on the strains and stresses in the arch. A shortening of kl of the distance l between the hinges effects a horizontal pressure

$$X_s = EJ\frac{kl}{\delta_{aa}},$$

or by introducing the value of δ_{aa}

$$X_s = \frac{15}{8}EJ\alpha\frac{k}{f^2}.$$

The Arch Without Hinges.—This type of arch has three statically indeterminate quantities and as those are chosen the normal force X_a, the transverse force X_b, and the bending moment X_c at the crown of the arch, acting from a point O (see Fig. 2) in the axis of symmetry, so situated that each of the three equations, from which the values of the statically indeterminate quantities are calculable, will contain only one of them. Their form will then become similar to that for the horizontal pressure of the arch with two hinges.

$$X_a = \frac{\delta_{ma}}{\delta_{aa}}$$

$$X_b = \frac{\delta_{mb}}{\delta_{cc}}$$

$$X_c = \frac{\delta_{mc}}{\delta_{cc}},$$

the statically determinate auxiliary system being two curved beams with one fixed and one unsupported end.

The "v" forces for the type of arch considered here are:

$$v^a = dx$$

$$v^b = xdx$$

$$v^c = ydx,$$

which again are equivalent to the continuous loads

$$z^a = 1$$

$$z^b = x$$

$$z^c = y.$$

The distance η from the point O to the line AB (Fig. 2) is determined by the equation

$$\eta\int_0^1 Z^a\,dx = \int_0^1 Z^a\,y'\,dx$$

$$\eta = \frac{2}{3}f^\circ,$$

y' being the ordinate of the centre line of the arch measured from AB. The equation for this centre line in the system of co-ordinates, as shown in Fig. 2 with O as origin is then

$$y = \frac{4f}{l^2}\left(\frac{1}{4}l^2 - x^2\right) - \eta = f\left[\frac{1}{3} - 4\left(\frac{x}{l}\right)^2\right].$$

The deflections δ_{ma}, δ_{mb} and δ_{mc} are calculated as moments produced by the loads z, acting on a beam of length l, fixed at the centre and having unsupported ends (Fig. 3). For the left and right half of the arch respectively

$$\delta_{ma} = -\int_{-\frac{1}{2}l}^{x}(x - x_1)\,Z^a dx_1 \text{ and } = -\int_{x}^{\frac{1}{2}l}(x_1 - x)\,Z^a\,dx_1.$$

In these expressions x is the abscissa of the point for which δ_{ma} is calculated and x_1 the varying abscissa of the

load element (see Fig. 3). The formulæ for δ_{mb} and δ_{mc} are analogous to that of δ_{ma}. The denominators of the equations for X_a, X_b and X_c are

$$\delta_{aa} = \int_{-\frac{1}{2}l}^{+\frac{1}{2}l} Z^2\, dx = l$$

$$\delta_{bb} = \int_{-\frac{1}{2}l}^{+\frac{1}{2}l} x^2\, dx = \frac{1}{12} l^3$$

$$\delta_{cc} = \int_{-\frac{1}{2}l}^{+\frac{1}{2}l} y^2\, dx + li^2 = \frac{4}{45} f^2 l + li^2.$$

The equations for the statically indeterminate quantities and now known:

$$\text{for } x < 0, \qquad X_a = -\frac{1}{8}\left(1 + 2\frac{x}{l}\right)^2,$$

$$X_b = \frac{1}{2}\left(1 - \frac{x}{l}\right)\left(1 + 2\frac{x}{l}\right)^2.$$

$$\text{For } x > 0, \quad X_a = -\frac{1}{8} l \left(1 - 2\frac{x}{l}\right)^2,$$

$$X_b = -\frac{1}{2}\left(1 + \frac{x}{l}\right)\left(1 - 2\frac{x}{l}\right)^2.$$

For both $x < 0$ and $x > 0$,

$$X_c = \frac{15}{64}\frac{l}{f}\,\alpha\left(1 - 2\frac{x}{l}\right)^2\left(1 + 2\frac{x}{l}\right),$$

$$\text{where } \alpha = \frac{1}{1 + \dfrac{45}{4}\dfrac{i^2}{f^2}}.$$

The bending moments and normal forces in the arch can then be computed. The normal force N is made equal to X_c

$$N = X_c = \frac{15}{4}\frac{l}{f}\,\alpha\left[\left(\frac{x}{l}\right)^2 - \frac{1}{4}\right] = \frac{l}{f} N_1.$$

The value of N_1 depends solely on the value of the ratio $\dfrac{x}{l}$ and on the value of α. Below, N_1 is given for $\alpha = 1$ and $\alpha = .9$, and $\dfrac{x}{l}$ varying with differences of .1.

$\frac{x}{l}$ =	0	.1	.2	.3	.4	.5
α = 1: N_1	.2344	.2100	.1654	.0960	.0304	.0000
α = .9: N_1	.2110	.1944	.1480	.0864	.0271	.0000

The line of influence of the bending moment M at a point of the arch with the co-ordinates x and y has the equation

$$M = l\left(\frac{M_o}{l} - \frac{X_a}{l} - \frac{x_1}{l} X_b - \frac{y_1}{f} H_1\right) = l\, M_1\,;$$

M_o being the corresponding ordinate of the line of influence of the bending moment in the statically determinate auxiliary system. M_1 depends only on the ratios $\dfrac{x_1}{l}$ and $\dfrac{x}{l}$, where x is the abscissa of the line of influence. In the table on page 657 is given the values of M_1 for varying $\dfrac{x}{l}$ and $\dfrac{x_1}{l}$ and for $\alpha = 1$ and .9 respectively.

By the aid of these lines of influence the maximum and minimum bending moments are finally determined

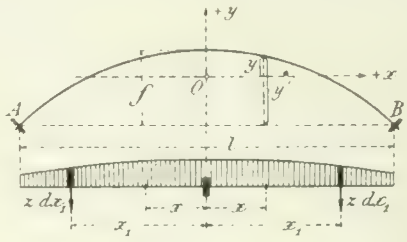

Fig. 3.

and also the simultaneously acting normal forces effected by a uniformly distributed live load p per unit length:

A uniformly distributed total load g per unit length gives

$$X_a = -\frac{gl^2}{24},\quad X_b = 0,\quad X_c = \frac{gl^2}{8f}\alpha,$$

and the bending moment at the various points of the arch is

$$M_{x_1} = \frac{1}{24} gl^2\left(1 - 12\frac{x_1^2}{l^2}\right)(1 - \alpha).$$

For $\alpha = 1$, there are no bending moments and consequently the maximum and minimum moments produced by a uniformly distributed live load have the same numerical values.

An increase of the temperature of $t°$ gives

$$X_{at} = 0,\quad X_{bt} = 0,\quad X_{ct} = \frac{45}{4} E\, J\, \alpha\, \frac{\epsilon t}{f^2}.$$

The influence of a yielding of the supports is readily computed by resolving the movements of the supports A and B into (1) a sinking (Δ_a at A and Δ_b at B), (2) a turning ϕ_a of the tangents at A (positive clockwise) and ϕ_b at B (positive anti-clockwise), (3) and a lengthening kl of the distance AB. The statically indeterminate quantities will then be

$$X_{au} = -EJ\frac{\phi_a - \phi_b}{\delta_{aa}}$$

$$X_{bu} = -EJ\frac{\Delta_b - \Delta_a + \frac{1}{2}l(\phi_b - \phi_a)}{\delta_{bb}}$$

$$X_{ou} = -EJ\frac{kl - \eta(\phi_a + \phi_b)}{\delta_{co}}$$

and the bending moments and normal forces in the arch are then directly computable.

PRELIMINARY ESTIMATES IN RAILROAD WORK.

SPEAKING from six years' experience as railroad engineer, Carl A. Gould, C.E., of the Northern Pacific R.R., states, in the Cornell Civil Engineer, that there are many items connected with the construction costs for which it is utterly impossible for even the most experienced to make provision at the time the first estimate is made.

With the growing tendency among the railroads to eliminate the old style of contract, containing prices for five or more classes of material, such as earth, hardpan, loose rock, shell rock, and solid rock, and place in its stead a contract containing only two classes of material, i.e., common excavation and solid rock, with the solid rock well defined and all material not coming under the solid rock definition classed as common excavation, it has left little chance for argument as to whether material encountered is of one class or another. As there is always a great difference in the prices for handling the different classes of material, naturally the contractor doing the work would feel that the man responsible for the final classification should be always on the alert to detect any difference in material and establish classification lines to be used on the final remeasured cross-section, on which is based the contractor's profit, or loss, as the case may be. As this method is practically impossible where all classes of material are encountered, the question resolves itself into one of personal opinion entirely. Now, as we are getting to a matter of dollars and cents, it is evident that it should require a man of some experience in handling material (in excavation) to arrive at what will be considered a fair percentage proportion for the work in question.

Even the most fair-minded contractors are apt to consider the engineers unfair, and on the other hand the engineers usually have good reason to think the contractors are asking too much. However, this condition is found, to a greater extent, among the smaller contractors and the engineers of limited experience. It is a fact, that it is a condition which arises on almost every piece of construction work where classification of material is made, and it behooves the engineer to become familiar with the character of the material to be moved, digging test-holes in cuts if necessary, in order that he may make a preliminary estimate which will compare favorably with the actual quantities of each class of material moved during the construction. Although the preliminary estimates are in no way binding on the railway company, this information should be furnished the contractor in order that he may place an intelligent bid, and thereby reduce the wrangling and friction with which so many of the construction jobs are closed.

There is another item which is often overlooked, and indeed difficult to determine at the outset, i.e., slides in cuts and settlement of soft ground under embankments. Allowance should be made for slides and settlements, especially where rainfall is heavy, cuts and fills deep, and ground water present. This allowance can only be approximate at best, but will be necessary when the engineer checks his final quantities with the preliminary estimates.

Over-haul is an item which is effected by all the variations in the quantities moved, and, therefore, the items above mentioned will all have an important part to play in the final over-haul quantity.

After the grading item comes the protection of the grading, of which there are many different kinds of construction. Cuts are protected by surface drains, ditches, track drains, bulkheads and retaining-wall, while in embankments the use of drains, retaining-walls, rip-rap and toe-walls are common. It requires much experience to foresee the necessity of protection against the possible conditions which may arise after the work has advanced.

Rock is usually used for the protection of the embankments, the rock varying in size from one cubic foot to five cubic yards. The most common use of rip-rap is placing it around masonry piers to prevent scouring; the river bed is here often washed out, thus letting the rock fall and requiring more rock than is contained within the slope limits.

There is also a considerable amount of rock which is lost in the handling. This, of course, would be governed more or less by the method of final measurement used, on which is based the contractor's estimate. Then, rock used for protection is an item on which a liberal allowance should be made for over-run. The writer has been on several pieces of rip-rap work and has never known the final quantity to be equal to, or less than, the original estimate. I would say that 20 per cent. is none too much to allow for over-run, from the theoretical sections, unless the contract states specifically the amount of rock to be used per unit, of length of line, which would amount to a "lump sum" bid for the work.

In tunnel costs we have something which contains a great many different items which can be figured from a knowledge of the excavation to be done, character of formation, etc., but there are many costs which cannot be foreseen, such as quicksand pockets, excess water, underground streams, and peculiar local formations, all items which it might be possible to overlook, even with the best of preliminary tests. This applies more to long tunnels than to short ones. Then in tunnels we have items which should be allowed for generously, and can only be properly estimated by the man who has had the conditions to deal with; it is impossible to use theoretical quantities without some allowance for the unexpected items of cost.

Super-structure of bridges is an item which can be accurately calculated as to weight, transportation, etc., while the foundations are always subjects requiring special study for the location in question. Anyone familiar with the different publications on bridge foundation work will note the great variation of unit costs of different bridges.

Although the condition should not exist, contractors usually look to the railroads to make good any loss on a piece of foundation work, in which unforeseen obstacles are met. As these obstacles are not figured in the original contractor's bid for the work, it may be fair for the railways to share some of the expense. Therefore, thorough testing of foundation sites should be made by the engineers, and contractors as well, in order to make an intelligent estimate of the cost of the work. Accurate preliminary estimates are accomplished only by the men of experience.

Drainage openings, such as arch culverts, pipes, box drains, and all sorts of pipe and tile drains are a constant source of trouble, both in construction and maintenance of railroad work.

Preliminary estimates should be made with a thorough investigation of the natural conditions surrounding the site of the drainage opening with a view to determining the nature of the ground, for foundation purposes, the accessibility to the site with materials, labor, and equipment, the necessity of maintaining a camp for one opening, and all local conditions which will in any way affect the location or construction of the opening. The preliminary work should be as familiar to the contractor as to the engineer, so that it will be thoroughly understood before the contract price is submitted.

Construction of the drainage openings may seem very simple at first sight, but often runs up into thousands of dollars for the simplest kinds of construction. The extra items which come up during the construction of the work and do not fall under any of the contract items, often increase the cost, of providing drainage, materially.

Protection of structures under high fills, washouts due to insufficient drainage, ground water seepage for which drainage has to be provided, stoppage of openings due to slides causing washouts, both in cuts and fills, are all items for which special provision should be made in preliminary estimates.

In Mr. Gould's own experience he has had 15,000 cubic yards of material washed from an embankment of 100 feet in length, due to an underground stream which was not detected until after the embankment material was placed and the weight forced the water back to the centre of the fill, where it broke out and caused the damage.

As a rule, the same engineer building the road-bed places the track and ballast. When ballasting, the line follows closely to the grading, it may be possible to keep the first cost estimate of ballast within the theoretical ballast limits. Often the road-bed is given a year to settle and acquire a more stable condition. This invariably requires more ballast, as it is impossible for the engineer to use a certain figure for shrinkage of embankments and have it agree exactly with the actual shrinkage which takes place. This, then, adds to the item of ballast.

In all construction work there is the item of waste which enters into the item of cost. With the very best instructions which can be given, and the best inspection which can be made, the engineer has, constantly, the item of waste to deal with.

Aside from the general construction work, there is the fluctuation of prices of materials, labor, machinery, etc. Although the railways in the West do not, as a rule, furnish materials, machinery, labor, etc., for construction work, it is not an uncommon occurrence. Small pieces of work, such as coal docks, water stations, depots, pipe culverts, are often done with railway company material.

After all, observes Mr. Gould, the engineer's life is one of continuous schooling and study along whatever line he may choose, and his value is measured by his ability to foresee conditions which will arise upon which he may plan and construct accordingly.

The Belgian Legation at Belgrade, Servia, reports that the town of Nisch proposes to raise a loan of £840,000 for canal works, construction of a line of tramways, and paving.

It is announced that Messrs. J. T. and C. Donohue have purchased all the stock of pulpwood formerly belonging to the East Canada Pulp Company, Limited, at Murray Bay, now in liquidation. The wood is in the yard booms and also uncut on the company's limits, on the Murray River and its tributaries. The purchasers have also acquired the new pulp mill

A comparison of the pulp industries in Canada and Denmark is interesting. In the little country of Denmark there are 230 pulp or paper mills. In Canada, according to the latest available statistics of the Dominion Forestry Branch, there are only 48 pulp mills in actual operation, though Canadian mills are many times larger than those in Denmark.

WATERPROOFING OF MASONRY AND BRIDGE FLOORS.

(Concluded from last week.)

Watertight Concrete Construction.—The results of laboratory experiments, supplemented by many examples from practice, have shown that watertight concrete can be made without the use of coatings, membranes or integral compounds. It is reasonable to assume that the porosity of concrete in certain cases is due to the fact that it contains small air spaces or voids throughout its mass, which are connected to each other more or less irregularly, and through which water passes, due either to the presence of the hydrostatic head or to capillary attraction. At the time of placing the concrete, some space is occupied by water carrying in suspension fine particles of cement. It is not necessary to assume that continuous capillary passages must be left in the concrete in order that as it dries the water may get out. It is probable that the excess of water passes out of the concrete in drying in such a state as to leave behind no pores through which water could again find access to the interior of the concrete or penetrate the structure.

The question of watertight concrete is then a problem of reducing the size and number of voids. Sands contain voids ranging from about 25 to 40 per cent. of the total volume of dry, loose sand. The proportions of cement to aggregate required to make a mixture of the maximum density with sands of these extreme values are about 1:1½ to 1:2½. Experience has demonstrated that mortars leaner than this are not suitable for work requiring considerable strength or density, so that the proportions used in ordinary engineering work are sufficiently rich to produce a watertight concrete, provided the aggregates possess the requisite qualities.

Samples of crusher-run limestone show 37 per cent. voids for each of two specimens, one having a maximum size stone passing 2½-in. sieve, the second passing 1¼-in. sieve. A broken stone passing a 2½-in. ring and retained on a ⅜-in. screen had 46 per cent. voids. Feret found about 52 per cent. voids in samples consisting of stones of about one size, for each of three different sizes. A similar variation in the percentage of voids with graduation in sizes of particles is found with gravel, for screened gravel of approximately one size of particles 40 per cent. to 45 per cent., for a well-graded gravel containing sand 25 per cent.

The amount of voids in a mixture of aggregate and cement is the least when the cement is just sufficient to fill the voids in the aggregate, since the cement paste itself is less dense than the coarse material of the aggregate.

A slight deficiency in cement produces a porous concrete because the unfilled voids are large enough to permit the passage of water, while properly-made concrete containing an excess of cement, though it may be of lower density than the former, is impermeable after hardening since the voids in the cement paste are too small to permit the passage of water.

Tests have failed to discover substances which, added to the concrete materials, will increase the density of the cement paste which fills the interstices between the particles of the aggregates, hence it is not believed that improvement as regards impermeability of concrete containing sufficient cement can be made by the addition of any material to the concrete mixture.

Some engineers apprehend that grading and proportioning according to ideal requirements necessitates extreme care and considerable expense, and, therefore, reject this method of obtaining watertight construction for one of the integral compounds, which is in reality based upon the same principle, or the results of which are uncertain as regards permanent impermeability and are detrimental to the strength of the concrete.

While it is true that concrete in which the amount of cement used is slightly in excess of the voids in the aggregate and in which the aggregate is so graded as to contain a minimum amount of voids, is an ideal mixture as regards density and strength, the requirements for watertight concrete do not demand the maintenance of exact proportions of this nature.

Experience has proved that materials, as supplied for large works, run uniformly enough to permit the proportioning and grading to be maintained at such a degree of excellence as to insure watertight construction at a very small expense for testing.

The following abstract from the results of laboratory tests made by the United States Bureau of Standards, Technologic Paper No. 3, are here quoted:—

These tests show that the permeability of concrete was not dependent entirely upon the quantity of cement used in proportion to the total aggregate, but depended also upon the ratio of coarse aggregate to fine aggregate. It will be observed in the case of sand No. 4, that the 1:1½:7½ proportion was decidedly more impermeable than the 1:2:4 proportion, although the former contains considerably less cement in proportion to aggregate.

Tests designed to show the effect of waterproofing materials, especially such as are added as fillers, should present a granulometric analysis of the aggregate, as comparisons are valueless without such information. It is to be expected that tests on mortar in which a sand was used having a deficiency of fine particles would show increased impermeability and increased strength upon the addition of a small amount of fine material. On the other hand, if the aggregate already contains as much fine material as it requires, addition of a fine material as waterproofing may be expected to decrease the strength and have no beneficial effect as a waterproofing material.

The method of proportioning the aggregate by mechanical analysis, which is described by Taylor & Thompson as exact and scientific, is recommended. The granulometric analysis requires a very inexpensive equipment and a complete analysis of an aggregate may be made in less than one hour's time. By its use definite data may be obtained upon which to base conclusions as to the necessity of and method of improving the concrete mixture.

In discussing the use of exterior coatings as against impermeable construction, the point is often advanced that although there is no doubt that watertight concrete can be made, the watertightness is of no avail when cracks occur in the structure.

The subject of cracking is one of design. Cracks are caused by failure to properly provide for primary stresses to which the structure is subjected, by faulty details, by settlement of foundation, by shrinkage of concrete when hardening in air, and by stresses developed in the concrete due to temperature changes.

Where concrete is to be deposited under circumstances which make it impracticable to construct watertight concrete, a special form of waterproofing should be provided.

Drainage.—The first requisite in designing any structure when water is to be kept out from the interior or from beneath, is to provide means of getting rid of the water as directly and as quickly as possible. Methods of providing drainage differ with the class of the structure.

During the construction of basements and pits, drainage can be maintained by pumping, and permanent drainage should be provided whenever a free outlet can be obtained.

Drainage of arches and culverts is provided by sloping the extrados to the back of the abutments and to the piers, placing down-spouts at piers and drain pipes behind abutments.

Drainage of retaining walls, abutments and subway walls is provided by one or more lines of drain pipes, placed at different elevations along the back of the walls.

In tunnels the extrados of the arch may be provided with sufficient slope to facilitate the flow of seepage water to the side walls. The back filling consists of porous materials, which will permit the ready passage of the water. Side-drains and connecting under-drains should be provided.

The drainage of subaqueous tunnels differs from the general problem of drainage, and is not concerned with waterproofing, in that it is a problem of handling water on the inside of the tunnel. This is usually accomplished by pumping from sumps.

The foundations of masonry reservoirs should be drained to insure the stability of the structure.

The solid floors of steel or reinforced concrete bridges may be drained by sloping the finished surface of the floor from the centre to each end, and carrying the water away back of the abutments, or the water can be carried away by downspouts at the intermediate points or supports.

Probably the commonest method of drainage solid-floor bridges is to slope the deck to one abutment or from a summit to both abutments. A continuous waterproofing layer extends over the deck and the top of the abutments and extends down over the back of the abutments to prevent the seepage of water at the bridge seat.

The surface of the waterproofing and its protection must have sufficient grade to carry away surface water. In the case of bridge floors, it is recommended that this grade be not less than 6 ins. in 100 ft. It is customary, when bridges are on sufficient grade to have the waterproofed surface at the same grade, the water being carried down over the back wall of the lower abutment, where drainage is provided by coarse backing and open-joint drains.

An objection to this method of drainage is made by some who find that in the spring, when the surface ice and snow melt and the filling back of the abutments is still in a frozen condition, the water does not escape freely, but accumulates and eventually seeps through at the end of the bridge and flows over the face of the abutment. Another objection is that in bridges having supports at curb lines and in the middle of the street, whether of flat slab construction or of steel troughs filled with concrete, cracks in the waterproof covering and in the concrete filling are likely to appear where joints are not provided over these supports, and where joints are provided, trouble is likely to be experienced in preventing the seepage of water.

When the troughs of steel bridges run transversely to the track and the filling in the troughs is omitted, the individual troughs may be drained through outlets in the bottom of the troughs into a drainage gutter suspended beneath the deck. These gutters may empty into pipes which run through the abutments and empty outside the embankment. Difficulty is found in obtaining a seal between the waterproofing and the drain pipe or opening in the trough.

When the troughs of solid floor steel bridges run parallel with the tracks, the water is usually carried over the abutments as in the concrete floor bridges.

A method sometimes used on solid-floor bridges in which the deck is filled up above the top of the steel with cement or bituminous concrete is to divide the floor of the bridge into rectangular sections, each of which is sloped to a drain pipe at one corner which carries the water through a down-spout at one of the supporting columns.

Much difficulty has been experienced with all types of waterproofing on steel bridges in preventing the leakage of water along the webs of girders. Although the concrete filling of the deck may be carried up above the top of the rail and great pains may be taken in providing a joint with a waterproofing material between the girder web and the concrete, leaks usually develop along the girder.

Several bridges have been built in which a special flashing angle or Z-bar extending the full length has been riveted to the inside of the girder to prevent the flow of water down the web of the girder. By carrying the concrete filling up underneath the outstanding leg of the flashing angle or Z-bar an efficient flashing is obtained. Good results have been obtained in the case of through girder bridges by carrying the concrete filling up under the top flange of the girder.

In considering the conclusions presented in Bulletin 64 in regard to reinforcing over supports, the following remarks of President Armstrong, of the Western Society of Engineers, are of interest:—

In large railroad structures it is impracticable to reinforce concrete so that there will be no cracks over a line of supports; good engineering would not permit such practice. It would be better to allow the concrete to crack or to leave a joint there, and then provide some means of keeping out the water. In the lighter structures, it is practicable to reinforce the concrete so that the reinforcement will prevent cracks at supports.

A joint in the waterproofing which will allow of movement of the ends of adjacent spans at supports is believed to be necessary. The use of a metal flashing between concrete slabs over joints has been used.

When the steel troughs run transversely to the track, a slight movement under traffic is to be expected at the connection of the troughs to the girders. Consequently, it would seem necessary to keep the water away from these connections by means of flashing and providing sufficient slope toward the centre of the floor, adjacent to the girders.

Figures show methods of waterproofing various structures.

Conclusions.—(1) Watertight concrete may be obtained by proper design, reinforcing the concrete against cracks due to expansion and contraction, using the proper proportions of cement and graded aggregates to secure the filling of voids and employing proper workmanship and close supervision.

(2) Membrane waterproofing, of either asphalt or pure coal-tar pitch in connection with felts and burlaps, with proper number of layers, good materials and workmanship and good working conditions, is recommended as good practice for waterproofing masonry, concrete and bridge floors.

(3) Permanent and direct drainage of bridge floors is essential to secure good results in waterproofing.

(4) Integral methods of waterproofing concrete have given some good results. Special care is required to properly proportion the concrete, mix thoroughly and deposit properly so as to have the void-filling compounds do the required duty; if this is neglected, the value of the compounds is lost and their waterproofing effect destroyed.

Careful tests should be made to ascertain the proper proportions and effectiveness of such compounds.

Integral compounds should be used with caution, ascertaining their chemical action on the concrete as well as their effect on its strength; as a general rule, integral compounds are not recommended, since the same results as to watertightness can be obtained by adding a small percentage of cement and properly grading the aggregate.

(5) Surface coatings, such as cement mortar, asphalt or bituminous mastic, if properly applied to masonry reinforced against cracks produced by settlement, expansion and contraction, may be successfully used for waterproofing arches, abutments, retaining walls, reservoirs and similar structures; for important work under high pressure of water these cannot be recommended for all conditions.

(6) Surface brush coating, such as oil paints and varnishes, are not considered reliable or lasting for waterproofing of masonry.

PROGRESS OF STREAM MEASUREMENTS IN WESTERN CANADA.

THE general scheme of stream measurement being carried out under the direction of F. H. Peters, C.E., Commissioner of Irrigation for the Department of the Interior, was outlined in *The Canadian Engineer* for November 3rd and 10th, 1910. The article referred to the report of P. M. Sauder, C.E., Chief Hydrographer. The department had been formed as a separate organization in the spring of 1909, with headquarters at Calgary. The article concerning it dealt with the organization, scope of the work, methods of measurement, etc. The investigation received further attention in our issue of May 30th, 1912, which issue contained an abstract of the progress report by Mr. Sauder, describing the various methods in use for determining discharge, mean velocity, etc.

The progress report for 1912 has just been issued and from it the following data, greatly condensed, has been extracted:—

Scope of Work.—The chief features of the stream measurement work are the collection of data relating to the flow of surface waters and a study of the conditions affecting this flow. Information is also collected concerning river profiles, the duration and magnitude of floods, irrigation, water-power, storage, seepage, etc., which may be of use in hydrographic studies.

This information is obtained by a series of observations at regular gauging stations which are established at suitable points. The selection of sites for these gauging stations and their maintenance depend largely upon the physical features and needs of the locality. If water is to be used for irrigation purposes the summer flow receives special attention; where it is required for power purposes, it becomes necessary to determine the minimum flow; if water is to be stored, information is obtained regarding the maximum flow. In all cases the duration of the different stages of the streams is recorded. Throughout the country gauging stations are maintained for general statistical purposes, to show the conditions existing through long periods. They are also used as primary stations, and their records in connection with short series of measurements will serve as bases for estimating the flow at other points in the drainage basin.

In the spring of 1912, field operations were commenced with 132 regular gauging stations on various streams in Alberta and Saskatchewan and 30 on irrigation ditches, and at present the regimen of flow is being studied at 139 regular gauging stations on streams and 40 on irrigation ditches. Winter records, which are so valuable for power investigations and municipal water supplies, have been given special attention latterly and records have been secured on almost all the important streams in these provinces during the past winter.

Organization.—The methods of carrying on the investigations were similar to those of previous years. Local residents were engaged to observe the gauge height at regular gauging stations. These observations were recorded in a book supplied by the department, and at the end of each week the observer copied the week's records on a postal card which was sent to the chief

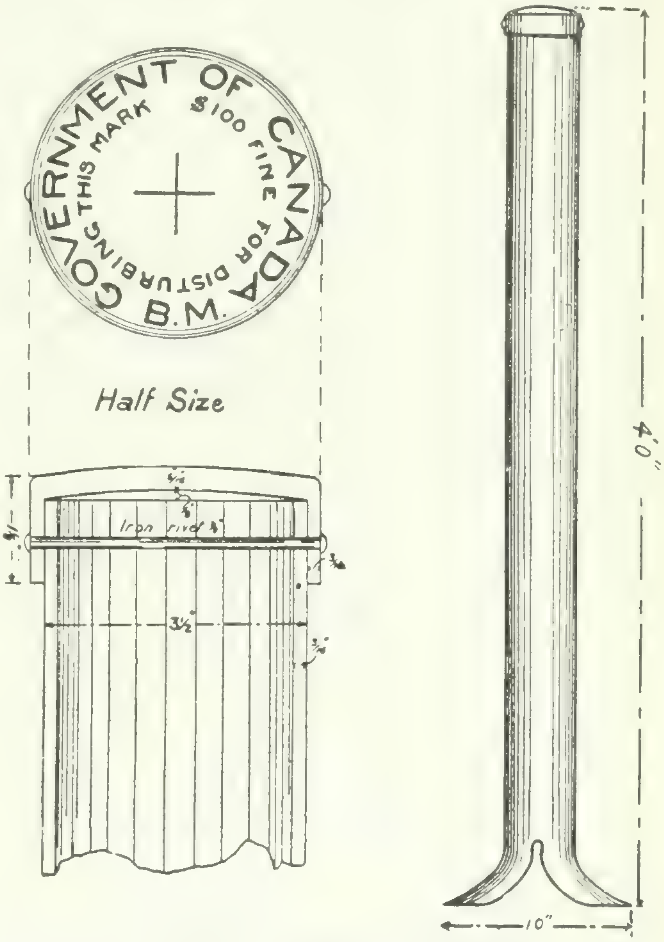

Fig. 1.—Permanent Benchmark Constructed of Iron, Adopted by the Irrigation Office.

hydrographer by the first convenient mail. The district hydrographers made regular visits to the gauging stations, usually once in every three weeks. On these visits they examined the observer's records, made discharge measurements and collected such information and data as would be of use in making estimates of the daily flow at the station. The results of the gaugings were transmitted by a postal card to the chief hydrographer. In the office these reports of the gauge height observers and the hydrographers were copied from the postal cards to regular forms and filed. At the close of the open season, some of the hydrographers returned to the office and assisted in the final computations and estimates of runoff. Gauge height-area, gauge height-mean velocity, and gauge height-discharge curves were plotted and rating tables constructed. Tables of discharge measurements, daily gauge height and discharge, and monthly discharge were also compiled.

The regular staff consisted of the chief hydrographer, ten assistant engineers, one recorder, one computor and one clerk. In order to overtake back work, three junior engineers were also employed for a portion of the year. The territory was divided for administrative purposes, into nine districts, viz., Banff, Calgary, Macleod, Cardston, Milk River, Western Cypress Hills, Eastern Cypress Hills, Moose Jaw, and Battleford. In each district there was an engineer and while in the field he had an assistant, and was equipped with the necessary gauging and surveying instruments. The tenth engineer was employed at rating meters and office work during the summer.

As winter records are of no value on a great many of the smaller streams the number of gauging stations maintained during the winter months was much less than during the summer, and by re-arranging the districts five engineers were able to do all the field work during the winter. The other five engineers and the three juniors have compiled the records.

Banff District.—This district included ten regular gauging stations. As the district has been in operation for some time, and several new stations had been established after a thorough reconnaissance in 1911, very few changes were made in the Banff district during 1912. In a few cases the conditions have been so unfavorable that gauge readings could not be obtained all winter, but in almost every case discharge measurements have been made regularly at intervals of about two weeks during the whole year at all of the stations excepting Forty-mile Creek, which was not established until July 31, 1912, and Jumpingpound Creek, which was not included during the winter months. During the year a large number of miscellaneous gaugings were made.

Owing to the comparatively low flow of Bow River during the winter months, the Calgary Power and Transmission Company, which has a power plant in operation at Horseshoe Falls and is building another plant at Kananaskis Falls, found it necessary to store water to tide over this period, and during the spring of 1912 built a dam on Cascade River near the mouth of Devil's Creek to increase the storage capacity of Lake Minewanka. The dam was completed before the high water period in June and the reservoir was therefore filled last summer (1912) and emptied during the winter. As this dam backs water up Devil's Creek the gauging station on this stream had to be abandoned, and it must be borne in mind, when using the records of flow of Cascade and Bow Rivers below Lake Minewanka reservoir, that after the first of June, 1912, the flow is affected by the operation of this reservoir and the records do not represent the true natural flow of the stream.

The town of Banff takes its domestic water supply from Forty-mile Creek, and as its requirements are gradually increasing it was thought advisable to take records of the flow of this stream. It is, however, impossible to get an observer above the intake of the waterworks and the station had to be established below the intake. The records, therefore, only represent the surplus flow which is not used by the town, and the consumption of the town has to be added to obtain the total natural flow of the stream.

Bath Creek is an important tributary of Bow River but no regular station has been established on it as it has been impossible in the past to secure an observer. This difficulty may not exist in future, and in such a case, a regular gauging station will be established.

Records will also be taken in future of the flow of Louise Creek, which is used by the Canadian Pacific Railway Company to develop power for use at the Lake Louise Chalet.

Further power development of Bow River depends very largely on the creation of storage reservoirs, to conserve flood water for use during the winter months, and during 1912 the Water Power Branch continued and completed its investigations of the upper regions of Bow River drainage basin. Whether any new stations are established in this district or any of the present ones are abandoned will depend largely on the report of the Water Power Branch and it is therefore awaited with much interest.

Calgary District.—This district included 18 regular gauging stations. It is the same as in 1911, except that a regular gauging station has been established on Highwood River above the mouth of Pekisko Creek. While this station was established primarily for statistical purposes, its records will probably be of considerable value in determining the possibilities of power development in this stream.

There were no special developments in this district during 1912, but as the canals being constructed by the Canadian Pacific Railway Company, the Southern Alberta Land Company, and the Alberta Land Company, are nearing completion, the value of the records of stream flow becomes more apparent. The first company will no doubt require more than the average low water flow of Bow River, and the other two depend entirely on the high water and flood discharge of the river for their water supply. Not only is it necessary to know the discharge of the river at these stages but also the duration of each stage.

The Southern Alberta Land Company and the Canadian Pacific Railway Company both anticipate the diversion of water throughout the whole of the open flow period, and anticipate a diversion that will approach the whole of the flow of the river so that the conditions of diversion for these large companies are becoming critical.

These problems cannot, however, be satisfactorily solved without records of stream flow covering a period of several years, and now that there are nearly five years' records of the flow of Bow River at Calgary approximate estimates can at least be made.

In designing a dam it is essential to know the maximum flood discharge of the stream in order to provide the necessary spillway to pass it without injury to the structure or adjoining property. During the past year all available data regarding the floods on Bow River was collected and estimates of the maximum flood discharge at different points were made.

Macleod District.—This district included 26 regular gauging stations. As it had been thoroughly reconnoitred during previous years it was not necessary to establish any new stations on rivers or creeks during 1912. As, however, some of the smaller streams in the Crow's Nest Pass are being used for domestic and industrial water supplies it will probably be advisable to establish regular gauging stations on some of these during the coming year.

Owing to the abundance of coal in this district, power is not very expensive and water power has not been developed. There are no great power possibilities but there are good opportunities for developing a small amount of power very cheaply. One very serious drawback to water power development is the absence of suitable sites for reservoirs to store water to augment the winter flow.

Irrigation is not generally required in this district and the developments in that line are therefore not very great.

Cardston District.—This district included 13 regular gauging stations.

In August, 1912, an arrangement was made with the United States Geological Survey by which regular gauging stations on St. Mary and Milk Rivers would in future be maintained jointly, each bearing half the cost of construction and maintenance. To get more accurate and satisfactory records it was decided to re-locate the stations at the best sites near the International Boundary and install automatic recording gauges.

There are only a few irrigation ditches in this district and the hydrographer therefore makes any inspections of these that are necessary. Unless urgent, they are usually made in the late summer or early fall when the streams are low and almost stationary, and need not be gauged as often as usual.

Milk River District.—The number of regular gauging stations in this district is comparatively small, 10 in number, but owing to shifting conditions at every one of them, it is necessary to make frequent gaugings in order to get reliable records, and as the distance between the stations is above the average the hydrographer cannot cover a larger district. The arrangement with the United States Geological Survey also includes gauging stations on Milk River and the South Branch of Milk River in this district.

Western Cypress Hills District.—This included 36 regular gauging stations.

Many of the ditch owners do not realize the value of records of the water used by them, and it has therefore been impossible to get good records on the ditches, but these will gradually improve, for, as irrigation increases, the irrigator will find the records very useful and will be only too glad to co-operate with the department in taking them.

This district includes a great many regular gauging stations on very small streams, but as every bit of available water will eventually be used for irrigation purposes, records on these are valuable.

While this is a rather large driving district, it can be covered satisfactorily except during the spring time. There is usually quite a large snow-fall in the hills during the winter and this usually runs off very quickly when spring opens up and the streams become quite high for a short time. Sometimes rains follow and keep the flow up, but not always, and the irrigators depending on high water and flood discharge of the stream should fill their reservoirs at the first opportunity. The records during early spring are therefore of considerable importance, but as the freshets are of short duration and travelling is difficult at that time, it is impossible for one hydrographer to cover the district properly. The hydrographer should be in the field on or shortly after the middle of March. This has not always been possible, owing to the fact that the fiscal year ends on the 31st of March and funds were not available. Provision should therefore be made in future estimates so that two hydrographers can be placed in this district during the spring and so that they can start field work about the middle of March.

Winter measurements would be of little value in this district and none have therefore been taken.

Eastern Cypress Hills District.—This district included 41 regular gauging stations. Beaver dams have become so numerous on some of the streams in it that it is difficult to get satisfactory records of the flow.

Moose Jaw District.—This district included 16 regular gauging stations.

The number of regular gauging stations in this district is comparatively small, but owing to the long distances between gauging stations and the importance of some of these it is impossible to increase the number.

There are now eight dams on Moose Jaw Creek in connection with domestic and industrial water supplies, and at least one other is contemplated. There is also about the same number of dams on Souris River. Though small and of an inferior quality, the water supply from these streams is very valuable. In order to intelligently administer the regulations and deal with new applications for water supply it is absolutely necessary to obtain continuous records of the flow of these streams at different points, and they are therefore being given special attention.

Winter records were taken only on Moose Jaw Creek near Moose Jaw, Qu'Appelle River at Lumsden, and South Saskatchewan River at Medicine Hat during January, February, and March, but were also obtained on Souris River at Estevan, and Swiftcurrent Creek at Swift Current in December. The station at Medicine Hat was included in the Macleod district, and the others in the Battleford district during January, February and March, but in December were a part of the new Moose Jaw district, which includes part of the old Battleford district.

Battleford District.—This district included 6 regular gauging stations. While there was no immediate use for records on the streams in this district when it was first started, the records are now of very great value to the Department of Public Works in their study of the North Saskatchewan River for navigation purposes, also to the Water Power Branch of this department and others interested in power development. There will be a good market for power in central Alberta, and many parties have been investigating the favorable water power sites and are awaiting records of the flow of the streams west and north of Edmonton.

During the winter almost continuous records were taken at all the regular gauging stations in this district. Those at Battleford, Prince Albert and Saskatoon were included in the new Moose Jaw district during December and the remainder in a new district called the Edmonton district. The Edmonton district included Red Deer River at Red Deer, North Saskatchewan River at Edmonton, and Athabasca River and its tributaries.

Bench Marks.—When the stream measurement work was first started, the gauges were usually referred to a bench mark on a wooden stake or stump of a tree. These were easily shifted or destroyed and were not satisfactory. In 1911, an iron bench mark of the type used by the United States Geological Survey was adopted, and was established as 62 regular gauging stations. During the past year, about 45 more were established and now almost all the gauges are either referred to a bench mark on a concrete pier or other permanent structure, or to one of these iron bench marks. Whenever an opportunity is afforded these are tied to the Canadian Pacific Railway or Dominion Government levels, to determine their elevation above sea level, and are therefore also a convenient reference for local levelling operations.

Fig. 1 shows the type and details of the permanent iron bench mark which is used. It is made of a piece of 3½-inch wrought iron pipe which is split at the bottom and expanded to a width of ten inches in order to anchor the tube solidly in the ground. The top is covered by a cap cast out of brass, or preferably aluminum bronze (10% Al. and 90% Cu.), which is secured to the top of the pipe by a long iron rivet. The inscription on the cap is cast in sunk-in letters giving a smooth surface to the cap. All

the exposed surfaces of the iron pipe are given a good coat of a first quality rust-resisting paint, and the bench mark is set with six inches projecting above the ground.

The brass cap for the iron bench mark may be modified and made with a stem about three inches long projecting on the under side which can be cemented into a drill hole in solid rock or masonry, to form a permanent and convenient bench mark.

Office Work.—The reports of the gauge height observers and the hydrographers are transmitted to the office by postal cards. These are copied to office forms and filed in a cabinet, which is carefully indexed and where they can be referred to at any time without trouble. As the engineers complete their computations, the results are entered on convenient forms and filed in the same cabinet.

A cabinet made up of four styles of drawers is used for filing the records. The top section is used for filing the gauge height books of the observers and the current meter note books of the hydrographers. The gauge height books are filed alphabetically according to the names of the gauging stations, while the current meter note books are filed alphabetically, according to the names of the hydrographers. The next section contains the postal cards sent in by the observers and the hydrographers. Both of these are filed alphabetically, according to the names of the gauging stations. The third section is made up of map drawers and contains the gauge height-area, gauge height-mean velocity and gauge height-discharge curves, and plotted cross-sections which are filed alphabetically, according to the names of the gauging stations. The same section contains the maps showing the outlines of the drainage basins, filed numerically, according to the number of the sectional sheet. The rating curves for the current meters are also filed in this section numerically, according to the office numbers of the meters. The bottom section of the cabinet consists of letter size pockets, alphabetically arranged for each gauging station. The tables of gauge heights, discharge measurements, daily gauge height and discharge, monthly discharge, a description of the station, and memos of any changes are filed in these pockets. The different rating tables for each meter are also filed numerically in this section and another drawer contains the monthly reports of the meteorological service.

The copying and filing of the reports of the gauge height observers and the hydrographers is entrusted to the office recorder. While doing this he must carefully examine all records to see that there are no errors, and where there are doubtful or impossible records it is his duty to have the data corrected or ascertain the cause of the unusual condition. He also makes out the pay list for the observers and conducts the correspondence relating to the records.

All computations are checked before being used or published. For this reason, as far as possible, men with some technical education, or students in science, are engaged as helpers. The gaugings are computed by the helper and his work is checked by the hydrographer. In some instances where there is a great deal of driving and camping out, the hydrographer cannot secure a helper who can compute discharges, and in that case he computes the discharges himself and his computations are checked in the office.

Gaugings of the flow under ice are usually made by using the multiple point method, and vertical velocity curves have to be plotted to determine the mean velocity in the vertical. The computation by this method is long and tedious and cannot be done by the hydrographer in the field. There are, therefore, a great many computations to be made in the office and the services of a computer are required.

Future Work.—The stream measurement work will be continued during the coming year in all the old districts; and every effort will be made to extend the territory covered, but the scope of the work is, of course, limited by the appropriation and staff available.

There are a number of important streams which rise in the mountains west of the Calgary and Edmonton Branch of the Canadian Pacific Railway. With the advent of railways, industries will soon be started in this district and the water supply will be an important factor. During the coming year it is proposed to have a hydrographer make a thorough reconnaissance of this district and make a study of the water supply, particularly to get records of the flow of the North Saskatchewan River and its tributaries. No doubt there are possibilities of water power development in this district, and records of stream flow will be wanted.

During the past year some information has been secured regarding the flow of Athabasca, McLeod and Pembina rivers. It will be impossible to secure observers wherever desired, but it is hoped during the coming year to make a careful reconnaissance of Athabasca River and its tributaries and establish regular gauging stations wherever the value of the records will warrant the expense of obtaining them. As elsewhere, our investigations in this district during the past year show that the minimum flow which occurs during the winter is much below the general expectation, and as there is a large number of possible power sites on this stream winter records are of much value, and special efforts will be made to get records at the more important points during the next winter.

Fortunately, excessive floods do not occur very frequently on the streams in Alberta and Saskatchewan, but, nevertheless, it is most important that these should not be under-estimated when designing dams, headgates, bridges, and other works on the streams. Not only does their destruction cause heavy loss to the owners of the structures but the lives and property of many other people are endangered. As above intimated, special studies of the maximum floods on Bow and North Saskatchewan Rivers at certain points were made during the past year. In future this subject will be given special attention, all available data will be collected, and the estimates tabulated in convenient form for use in designing structures at different points on each large stream.

It might not be amiss to refer to the importance of studying the winter flow of some of the smaller streams in the more thickly populated districts. Domestic and industrial water supplies have been installed to take their supply from streams which, judging from their open water flow, would provide an ample supply at all times. In several instances waterworks have been installed without sufficient knowledge of the winter flow, with the result that the supply proved to be inadequate during the winter. When the supply is from open streams this can very often be overcome by creating storage reservoirs at a nominal cost, but in cases where the supply is from springs there is seldom any remedy. As many of the towns on the prairie are dependent for their water supply on streams with very small flow during the winter months, it is most important that they should know before designing their works exactly what that flow is, so that the scheme will include the necessary storage facilities. The railways are also becoming perplexed as to how to get enough water in some localities to operate their trains during the winter

months and during the past winter had, in some instances, to haul water for very long distances, owing to the failure of their water supply at certain tanks. Records of the discharge of all the streams in these localities, even though very small, are very valuable during both summer and winter.

Many engineers make their estimates of stream flow from precipitation records. It should, however, be pointed out that precipitation records gathered at a few isolated points are of very little value in estimating the probable discharge of the streams in Alberta and Saskatchewan and very often are misleading. The physical features and the precipitation are so varied within the same drainage basin that no reliable estimates can be made. Streams, such as Bow River, for instance, very often have a comparatively large run-off during a comparatively hot, dry summer, due to the fact that a much larger quantity of snow and ice is melted in the mountains in a hot, dry summer than in a cold, wet summer. In a cold, wet summer the precipitation in the mountains often falls as snow and is stored instead of coming down to still further swell the already high streams. This same condition is found on the North Saskatchewan and all other large streams whose main sources are in the mountains. It is, for instance, impossible to estimate the probable discharge of the North Saskatchewan River at Prince Albert from precipitation records and the only reliable data to use are the records of stream flow.

To arrive at anything approaching a reliable estimate of the flow of a stream at different stages and the duration of those stages, a series of continuous records of discharge extending over a considerable period is absolutely necessary. George W. Rafter, in Water Supply Paper No. 80, published by the United States Geological Survey, says: "Further, it can be stated that for records from twenty years to thirty-five years in length the error may be expected to vary from 3.25 per cent. down to 2 per cent., and that, for the shorter periods of five, ten and fifteen years the probable extreme deviation from the mean would be 15 per cent., 8.25 per cent., and 4.75 per cent. respectively.

Mr. Rafter says, further, that with less complete records "Mr. Henry reached the conclusion that at least 35 to 40 years' observations are required to obtain a result that will not depart more than 5 per cent. from the true normal. The average variation of a 35-year period was found to be 5 per cent., and for a 40-year period 3 per cent."

The records of this office do not extend over a period of more than five years on any stream, and during that period interruptions have occurred, due to lack of funds and staff. Proper provision should be made so that this work will not in future be subject to these interruptions.

The water supply is one of the most important resources of a country, and an accurate knowledge of the flow of water in nearly all important streams is essential for the solution of many problems in connection with navigation, water-power, irrigation, domestic and industrial water supplies, sewage disposal, mining, bridge building, river-channel protection, flood prevention, and storage for conservation of flood waters. The records are being used quite extensively now by engineers and the field of operations should be extended to include other parts, if not the whole of Canada.

The work is in charge of P. M. Sauder, C.E., Chief Hydrographer. His first assistant since January 1st, 1913, has been G. H. Whyte, B.A.Sc., and his second assistant, G. R. Elliott, B.A.Sc.

PRESENT DAY WATER FILTRATION PRACTICE.

THE two methods of water filtration; namely, by slow sand and by rapid sand filters, English and American types respectively, are traced in their development, are compared as to their relative applicability to meet varying sets of conditions and are discussed as to the features of operation upon which the efficiencies of both depend, in a paper to be presented by Mr. George A. Johnson, Consulting Engineer, New York City, at the coming meeting of the American Water-Works Association in Philadelphia. The writer dwells also to some extent upon the questions of comparative cost of filtered water as obtained by the two methods.

According to Mr. Johnson, the first municipal water filter was built at London 85 years ago. It was built to perform only the functions of a mechanical strainer for the removal of suspended matter. At that time the two most important water-borne diseases (typhoid fever and cholera) had not then been discovered, and the germ theory of diseases was not advanced until some 20 years later. The first official recognition of water filtration as a means of reducing the dangers in impure drinking water took the form of an Act of Parliament in 1852, which made compulsory the filtration of the entire water supply of the metropolitan district of London.

This filter, as well as all those which followed during the succeeding 50 years, was of the slow sand type. After considerable scientific investigation, particularly in Germany, this type found its way to America and appeared at Poughkeepsie, N.Y., about 1875, as the first municipal water filtration plant in America. Its adoption was slow, however, and, in 1890, only 35,000 people in America were being served with water so filtered.

A patent for a process in which a coagulant was added to the raw water before filtration was granted in 1884, and with the use of coagulating chemicals the mechanical or rapid sand filter developed.

Up to January, 1914, some 30 slow sand filtration plants were put in operation, or were at that date under construction in the United States. They have a daily filtration capacity of 840,000,000 gallons and are designed to serve a total population of 5,500,000. Of this population 73% is served by the filter plants installed in eight cities, while the remaining population is widely scattered through some twenty cities.

Mr. Johnson's paper takes into consideration the operation and efficiency of the plants at Lawrence, Mass.; Albany, N.Y.; Washington, D.C.; Philadelphia, Pa., and Pittsburgh, Pa., showing the difficulties under which filters of this type are obliged to work when called upon to treat muddy waters. It is noted that in every instance, with the sole exception of Lawrence, the original design has been improved upon and the preparatory treatment of the work made more complete. This preparatory treatment consisted in some instances of roughing filters, the use of coagulant, or both, while at practically all slow sand filter plants in the United States the final filtered product is sterilized with hypochlorites. Mr. Johnson states that with the exception of Lawrence, Providence and New Haven, it is becoming difficult to locate the slow sand filter plant which does not in some important respect depart from the original ideas of what constituted that system of water purification or which does not in some way make use of certain inherent ideas upon which are based the rapid sand system of water filtration.

Since the installation of the first municipal rapid sand filtration plant at Somerville, N.J., in 1885, upwards of 450 municipal filter plants of this type have been built or are now under construction in the United States. Those operating have a daily capacity totalling 1,745,000,000 gallons and approximately 12,000,000 people are being supplied with water so filtered.

Between 1890 and 1900 there was much scientific investigation into the merits of the new process. These studies were in no small measure responsible for the wonderful growth of rapid sand filtration during the past 15 years, as the theory of the process was thoroughly worked out and the idea placed upon solid footing.

The type of construction changed abruptly about 1900, rectangular concrete tanks frequently replacing the circular wooden or steel tanks formerly used. The new type necessitated the use of compressed air to agitate the sand layer while washing the filter and later the application of wash water at high velocities. These methods became general, supplanting the mechanical stirrers and wash water at low velocity used in the old type of rapid sand filters, and from which they had derived the name of mechanical filter.

Among the 450 plants mentioned above, the largest are situated at Little Falls, N.J.; New Orleans, La.; Cincinnati, Ohio; Louisville, Ky., and Columbus, Ohio, the respective daily capacities being 32, 44, 112, 36 and 30 million gallons daily. Mr. Johnson's paper describes the experiences of these five plants.

Relative Cost of Slow Sand and Rapid Sand Fltration.—Construction.—In discussing the cost of building water filtration works of the slow sand and rapid sand types, respectively, Mr. Johnson gives consideration only to those items referring to the filter plant proper. Cost of land, pumping machinery, outside connecting piping, intakes, etc., in fact everything outside the filtration plant proper, is not considered. The following is a summary of this portion of his paper:

For slow sand filter costs the items will include the necessary filter buildings and filters with all appurtenances, all inside piping, sand handling apparatus, preliminary sedimentation basins, preliminary filters and appurtenances and clear water reservoirs.

For rapid sand filter costs the items will include the filter buildings and filters with all appurtenances, all inside piping, filter washing apparatus, coagulating and clear water basins. Thus a fairly good idea may be had of the relative cost of building purification plants of the two types.

It is true that, on account of the much greater area required, the cost for land is far greater in the case of slow sand filtration systems than for rapid sand systems. Roughly, other things being equal, land will cost twenty times as much for a slow sand filter installation as for a rapid sand plant. Furthermore, in large projects, it is often difficult conveniently to locate a site for slow sand filters, while for a rapid sand filter plant it is a relatively easy matter as a rule. If it is necessary to go a long distance in locating an extensive and suitable area of land for a slow sand filter site there is incurred a large expense for a conduit to bring the filtered water to the city. This is very rarely necessary in the case of rapid sand filter projects. So that, in studying the comparative figures which follow, it must distinctly be borne in mind that the costs given for slow sand filter installations are really low, since the important considerations just mentioned are not charged against them.

Cost of construction of slow sand and rapid sand water filtration plants.

City.	Kind of sand filters.	Present daily filtering capacity.	Approximate cost per million gallons daily capacity.
Albany, N.Y.	Slow	20,000,000	$20,000 (a)
Pittsburgh, Pa.	Slow	200,000,000	26,000 (a)
Philadelphia, Pa.:			
Torresdale	Slow	250,000,000	37,700 (a)
Upper Roxborough ..	Slow	28,000,000	29,800
Lower Roxborough ..	Slow	17,000,000	26,300 (a)
Belmont	Slow	60,000,000	45,200 (a)
Washington, D.C.	Slow	100,000,000	30,000 (b)
Cincinnati, Ohio	Rapid	112,000,000	11,400 (c)
Columbus, Ohio	Rapid	30,000,000	13,000 (d)
Dallas, Texas	Rapid	15,000,000	13,000
Harrisburg, Pa.	Rapid	16,000,000	10,300
Little Falls, N.J.	Rapid	32,000,000	15,000
Lorain, Ohio	Rapid	6,000,000	14,000
New Milford, N.J.	Rapid	24,000,000	11,000
Watertown, N.Y.	Rapid	8,000,000	11,250
Weighted averages	Slow	....	$32,600
	Rapid	....	12,100

(a) Cost of preliminary filters included.

(b) Cost of Dalecarlia Reservoir not included. Cost of McMillan Park Reservoir included, and also cost of remodeling Georgetown Reservoir, as well as cost of coagulating basin.

(c) Cost of large plain sedimentation basin not included.

(d) Cost of softening works not included.

The above figures show that the approximate relative cost of building the slow sand and rapid sand filter plants mentioned was $32,600 and $12,100 respectively, per million gallons daily capacity. At 5 per cent. the fixed charges on these sums would amount to $4.47 and $1.66, respectively, per million gallons of water filtered.

Operation and Maintenance.—The cost of operation and maintenance of filtration plants in a large measure, varies, of course, with the quality of the raw water. In a general way the following examples will serve to show the charges ordinarily made against the operation and maintenance of representative water filter plants in this country.

Cost of operation and maintenance of slow sand and rapid sand filtration plants.

Year.	City.	Kind of sand filters.		Average volume of water filtered daily.	Cost of operation and maintenance per million gallons of water filtered.
1911	Albany, N.Y.	Slow		20,000,000	$2.50
1912	Pittsburgh, Pa. ..	Slow		100,000,000	3.41
1911	Philadelphia, Pa. .	Slow	(a)	9,000,000	5.62
1911	Philadelphia, Pa. .	Slow	(b)	13,000,000	3.59
1911	Philadelphia, Pa. .	Slow	(c)	38,000,000	3.88
1911	Philadelphia, Pa. .	Slow	(d)	202,000,000	1.91
1912	Washington, D.C. .	Slow		62,000,000	4.01
1912	Cincinnati, Ohio	Rapid		50,000,000	4.12
1911	Harrisburg, Pa. .	Rapid		9,000,000	3.03
1912	Little Falls, N.J.	Rapid		30,000,000	3.20
1912	Louisville, Ky. ..	Rapid		25,000,000	3.48
1912	New Orleans, La. .	Rapid		16,000,000	6.32
	Weighted Average ..	Slow		....	$2.86
		Rapid		...	4.04

(a) Lower Roxborough; (b) Upper Roxborough; (c) Belmont; (d) Torresdale.

To summarize, the average cost of building seven of the largest and most modern slow sand filter plants was $32,600 per million gallons daily capacity; and, likewise, the average cost of building six of the largest, and two medium size, rapid sand filtration plants was $12,100 per million gallons daily capacity. The average cost of operation and maintenance varied widely, of course, but averaged $2.86 and $4.04 per million gallons of water filtered by the slow sand and rapid sand filters, respectively. Adding these last figures to the fixed charge on the first cost of construction makes up the following totals:—

Slow sand filtration ....$7.33 per million gallons
Rapid sand filtration ....$5.70 per million gallons

Relative Hygienic Efficiency of Slow Sand and Rapid Sand Filters.—In former years the slow sand process of water purification was favored by the majority of sanitarians and engineers because it was considered that, as compared with the rapid sand process, the former process was more nearly a "natural" one and hence less liable to failure. The actual results obtained from both systems have long since shown this assumption to be unfounded. Both processes require careful and intelligent management, but there is no room for doubt that if there is any choice between the two as regards hygienic efficiency it belongs to the rapid sand process. Well designed and built plants of this type not only can purify water of any character, turbid, colored or clear, so that the filtered product will always be clear and colorless, but are less liable to show sharp diminution in bacterial (hygienic) efficiency in cold winter months, or when the character of the raw water is seriously contaminated with certain industrial wastes. Chemical treatment is an integral part of all rapid sand filter processes, but is a makeshift when used in conjunction with slow sand filter processes; and the more complicated the chemical treatment prior to filtration the more likely are the final slow sand filters to fail.

In brief, wherever chemicals are or should be used in the preparation of water for filtration, it is proof that the slow sand filter is out of its element and in a field which, on grounds of economy at least, belongs exclusively to the rapid sand system.

In support of the assertion that rapid sand systems are at least the equal of slow sand systems with respect to hygienic efficiency, Mr. Johnson presents a table showing the typhoid fever death rate in certain American cities using slow sand or rapid sand filters. It is seen that the residual typhoid in those cities having rapid sand filters is 27 per cent. less than in those having slow sand filters.

Comparative Growth of Rapid and Slow Sand Filtration in the United States.—The growth of water filtration in the United States, particularly during the last dozen years or so, has been remarkable. In 1900 but 1,860,000 people were being supplied with filtered water, and in 1905 the United States was inferior to Japan in this regard. Since 1900 the population so supplied has increased by 830 per cent.

In the decade 1900-1910 slow sand filtration showed a remarkable increase with respect to the population supplied from such plants. This was largely due to the construction of the plants in Philadelphia, Pittsburgh and Washington, these three cities contributing over 2,000,000 of the increased population served by that system of filtration noted in the decade 1900-1910, namely 3,523,000. The increase during the same period in the number of people supplied with water from rapid sand filter plants was even more remarkable, totaling 5,422,000, or 54 per cent. greater than in the case of the slow sand filter systems.

"Since 1910 the slow sand filter has failed to maintain the rate of increase noted during the previous decade, the additional population served at this date, as compared with 1910, being 1,515,000. During the same period the additional population served by rapid sand filters was 4,971,000. The proof is plain, therefore, that the slow sand filter has about reached its limit, while the rapid sand filter is growing faster each succeeding year."

The paper contains tables and diagrams serving to show how the practice of water filtration has grown, and the respective parts which slow sand and rapid sand filter processes have played in the development of this important branch of municipal sanitation.

It is to be noted that of 40.68 per cent. of urban population supplied with filtered water 27.98 per cent. is supplied from rapid sand filters.

GOOD ROADS PREVENT DISEASE.

Few persons, on first thought, would see any possible connection between good roads and good health. Yet the State Boards of Health of Ohio and Kansas say that by the removal of weeds and trash good roads can and will prevent disease. Weeds and trash prevent the prompt evaporation of moisture and promote retention of ground water. This makes ideal breeding spots for mosquitoes, flies and other insects, which are known as disease carriers, not to mention chinch bugs, hoppers and other insects which are crop damagers. Furthermore, an undergrowth of weeds invites the dumping of garbage and manure by offering concealment, of which fact careless and thoughtless people are prone to take advantage, thus increasing the facility of insect breeding and providing these insect carriers with proper material for disease transmission.

Good roads also prevent disease by providing good drainage. Many farms have no means of drainage except by ditches along roadways. Open ditches, clear of brush and debris, with hardened surface and proper fall, afford these farms the opportunity of ridding themselves of many a stagnant pool. The removal of weeds, proper road grading, surface hardening and oiling, insures prompt drainage of all pool, ditch and surface water, removing the possibility of insect breeders, for none can multiply without moisture. Road oiling in itself is destructive of insect larvæ, especially mosquitoes—a well-known fact. Dry roads offer pedestrians, and notably children who are compelled to walk to and from school, dry shoes and feet. While colds are due to specific germs, yet it is a well-known fact that cold, wet feet and chilled limbs lower the resistance of individuals and make them more favorable subjects for infections of the respiratory passages, including pneumonia and tuberculosis. Good roads prevent disease by setting an example to adjoining farm premises. Good roads promote travel and set an example to the farmer whose premises are bordered by them. The comparison of a well-graded, clean highway with an unkempt and trashy barnyard adjoining is sufficient to stimulate every landowner to a clean-up. Pride compels him to offer to passers-by a neat-appearing and attractive house and barnyard. Results are only too obvious. Good roads are active disease prevention agencies, aside from their financial and commercial value.

THE GRADING AND DRAINAGE OF ROADS.

DETERMINATION of the amount of grading to be done in connection with the improvement of any highway depends upon the amount and nature of the travel and the topography. Excessive grades increase the cost of transportation and also add a heavy burden of maintenance, and it is always advantageous to lengthen a road and eliminate an excessive grade. This, as a whole, should be governed by the axioms enumerated by S. D. Foster, Chief Engineer, Pennsylvania State Highway Department, in his paper to the American Road Builders' Association in December last. These axioms may be stated as follows:—

1. No greater load can be moved over a highway than is moved over the maximum grade. 2. It is generally true that a road over a hill is equal in length to one around the base. 3. If the tendency of the topography is toward a continued elevation, the grade line should never be allowed to have a descending grade, and vice versa.

Sacrifice of straightness or of grade will be dedependent upon the predominant nature of the travel. Where horse-drawn vehicles predominate, alignment should give way to the lessening of the grade, as horse-drawn vehicles demand easy grade in preference to straight roads; where motor travel predominates, the grades should give way to alignment, for the rapidly increasing use of motor vehicles places a new responsibility upon the roadmaker—the reduction of danger to life and property, which necessitates building highways with long, easy curves.

Drainage.—In determining the amount of drainage it is well to remember that the ability of earth or soils to sustain loads depends largely upon the moisture present. Most soils can be compacted to form a good, firm foundation as long as they are kept dry, but when wet they become soft and in a great measure lose their sustaining power. The main problem, therefore, in the construction of a highway is drainage, which is dependent upon proper location. If the ground is level and not subject to flood there is seldom difficulty in location, but marshy ground underlaid with quicksands is expensive to deal with and generally should be avoided, even though it involves a considerable detour. A quicksand well drained often makes an excellent foundation for a road; the drainage, however, must be thorough and rapid. If the ground is level and subject to flood, mainly by backwater, an adequate number of small drains will usually accomplish the desired result, except that it may cost a good deal to raise the grade of the road above flood level. Cases sometimes arise where it is more economical to build a road floodproof at a lower level and submit to an occasional interruption of traffic than to make a wide detour or go to the great expense of a fill or viaduct.

Roads Subjected to Floods.—If the ground is level and subject to floods running at high velocity great care is necessary. The natural channel of the stream is altogether insufficient to carry the flood water, and, if the bridge crossing the stream is made large enough to permit the flow to pass under it, extensive erosion is liable to take place. If overflow bridges are built they are very likely to cause formation of side channels. Usually, the best treatment is to build the bridge large enough to pass the whole stream in flood time, straighten and widen the channel of the stream as much as possible, remove obstructions and protect the banks at exposed points.

In some cases it may be necessary to allow the flood water to overflow the road at some points, which must, of course, be made floodproof. Where such overflow points are provided, they should be made long and shallow to reduce as much as possible the velocity of the current flowing over them; otherwise adjacent property will suffer unnecessarily. These low places should also be so located as to reduce the actual damage to the minimum, as it is the duty of the public official to protect the just rights of all parties. If the proposed road crosses a narrow valley with a rapid stream, it is almost always best to give the bridge ample waterway and fix the grade above the reach of high water, taking care, of course, to protect all exposed points against erosion. Where valleys are to be crossed it is always better to cross them where they are narrow and the streams rapid. Such conditions reduce the amount of embankment required and also the span of the bridge, requiring more substantial construction, but proving more economical and more enduring.

One other condition met with frequently upon the highways of Pennsylvania is that arising from the tendency of one stratum of soil to slip upon another and thus cause landslides. These are most difficult and expensive to deal with, and it is seldom if ever worth while to attempt to hold such a movement of earth in place by piles or retaining walls. The only sure treatment is the thorough cutting off of the water before it enters the sliding mass. French drains with suitable laterals are generally better than tile drains, the usefulness of which may be destroyed by a slight movement in the slide. The drainage must be ample, as regards the sizes and lengths of the drains and the sufficiency of the outlets. This is sometimes a very expensive treatment, but if well done a permanent cure is generally effected.

The Ontario Government has secured an option upon timber rights in a large section of the limits of the Pembroke Lumber Company in and immediately adjoining the Algonquin National Park. The limit taken over, and by order-in-Council brought within the park, is chiefly valuable to the province from the fact that it contains a splendid stand of young pine. The price to be paid by the Government is $185,000.

Repairing a Locomotive with Portland Cement.—The Chesapeake and Ohio Railroad Company have successfully used Portland cement for the temporary repair of a fissure, 3-in. long, in the steam chest of a locomotive engine. Cement was employed because the part affected was inaccessible for the customary treatment. It is stated that after having been in service for eight months, the locomotive was sent to the shops for general overhauling, when the cement lining was found to be so perfect that it was left in place.

The conference of the International Waterways Commission just concluded at Washington, D.C., has resulted in the decision of the commission, first, to employ leading sanitary engineers to study the problem of the pollution of boundary waterways, then to give them a hearing, which will be in New York about the middle of May. After that hearings will be held in the various cities and towns affected, Buffalo and Detroit, as the two largest, being the first to be visited by the commission. The commission will meet again at Sault Ste. Marie on May 4th to investigate the water power project which American and Canadian concerns desire to build at the point, and which will affect the level of Lake Superior.

Sir Robert Perks, the English contractor, has received a contract from the Russian Government to build what will be practically a new harbor at Vladivostock. The port has deep water and other natural advantages, but so far little has been done for its improvement by the government of the Czar. Some time ago the Russian Government undertook to double-track the great Trans-Siberian Railway from the Pacific to St. Petersburg, and that work being now near completion, attention is turned to the proposed terminals which will cost millions of roubles. The contract which Sir Robert is soon to enter upon will comprise accommodation for both war vessels and merchant shipping and the contractor has several years to complete the work.

CONTENTS OF THIS ISSUE.

FUNDS FOR HIGHER TECHNICAL EDUCATION.

The Royal Commission, appointed in 1910 to enquire into the needs and present equipment of the Dominion of Canada with respect to industrial training and technical education, has recently submitted a voluminous report in which many findings are presented and recommendations made. Its investigations into the systems of education in this and other countries have disclosed many shortcomings as well as some commendable features.

In the matter, for instance, of technical education of university or college grade, although a complete study of the organization of institutions and causes of instruction was not entered into, a study of the effects of the higher forms of technical education upon progress in industry and trade brought out one outstanding fact.

In France, Germany, Switzerland and the United States, the power and influence of technical education of the highest types appeared to be greater than in the United Kingdom or in Canada. In England, moreover, the opinion most frequently heard—and it was earnestly urged—was to the effect that hereafter the industries must somehow secure the services of more men of the highest scientific attainments with thorough technical training, or her manufacturers and merchants will not be able to hold their own against foreign competition.

The faculties of applied science of colleges and universities in Canada have the reputation of preparing engineers for professional work in a thorough and satisfactory manner. From what was learned abroad by the commission, the opinion appears to prevail that students in technical colleges, at some time before they graduate, should have obtained experience with materials, tools, machines and products for the purpose of giving them a clear understanding of principles and a correct knowledge of the conditions of production and construction which prevail in shops and factories. It is not important that they should have enough practice to develop either skill or speed as workmen in manipulative labor.

Technical education for the preparation of technical engineers, and other persons being trained for professional work of a grade and rank similar to theirs, would be improved, states the commission, by further extensions in the direction indicated by the practice in Germany, where industry and trade require, precisely like the German army, a number of intellectually highly trained officers, who are recruited almost exclusively from the technical colleges. These colleges educate the leaders of industry and also the state and municipal officials who are entrusted with the execution of technical problems.

The universities and colleges in Canada are providing technical courses to meet the demands from an increasing number of students. The rapid growth and development of the country, and the further application of science and scientific methods to all forms of production, construction, conservation and administration, will call for still larger numbers of graduates. In consequences the universities and colleges are sure to require increased financial support. The commission expresses itself to be of the opinion that this should be provided from some source without causing the fees required from students to be so high as to exclude suitable young persons who may seek the highest grade of technical instruction.

The report, as a whole, is well seasoned with admonitions that the higher educational centres of Canada are not yet at such a stage of excellence and proficiency that the country can sit back and entertain thoughts of retrenchment of financial support. The advice which the commission imparts in this respect is most timely, as the

severity of lack of funds is making itself keenly felt in some of our institutions upon which we are placing a great deal of dependence for a continuation of Canadian enterprise and awakening. When, after a world-wide survey of industrial and educational conditions, Canada is advised by its Royal Commission that an increase of financial support is necessary for the proper education which its national problems demand, there is only one thing to do.

CANADIAN ROAD CONGRESS.

Canada's first Good Roads Congress will be held in the "Arena" at Montreal, May 18th to 23rd, and it is expected that it will be attended by several hundred delegates from all parts of the Dominion, and by many from the United States, all of them enthusiastically interested in the international awakening to the necessity for the betterment of urban and interurban streets and highways.

Geo. A. McNamee, secretary of the Automobile Club of Canada, has been appointed secretary-treasurer of the congress, and has associated with him the following men: Former Alderman U. H. Dandurand, of Montreal, is chairman of the congress; H. W. Pillow, president of the Automobile Club of Canada, and Oliver Hezzlewood, president of the Canadian Automobile Federation, are among the active workers.

Hon. Chas. Tessier, Minister of Good Roads for the Province of Quebec, elected to this position during the last week in March, has given the congress his official sanction. Endorsations have been received from W. A. McLean, president of the American Road Builders' Association; W. J. Kerr, president of the Canadian Highways Association, of Vancouver, and F. R. Robinson, chairman of the Saskatchewan Highway Commission, of Regina.

The congress will be opened at 3 p.m., May 18th, by the Honorable Lieutenant-Governor of the Province of Quebec, Sir Francois Langelier, assisted by Sir John M. Gibson, the Lieutenant-Governor of the Province of Ontario. Official representatives will be present from the French, British, United States and Canadian governments, and addresses will be given by more than two score men of prominence.

Over $60,000,000 is available in appropriations in Canada for expenditure for good roads during the current year. The congress delegates will debate, as one of their most important problems, the best and wisest method for outlaying this huge sum. Thirty-three millions is the amount which will be spent under provincial supervision, and the other twenty-seven millions will be spent by cities, towns and townships. This estimate, made by Geo. A. McNamee a few weeks ago, is said to be a conservative one, and has since been augmented by Ontario's appropriation.

EDITORIAL COMMENT.

Work on the Welland Canal has made remarkable progress during the past month. Sections I., II., and III. are being operated upon while Section IV.-A will be commenced immediately. This sub-section was awarded last week to Maguire and Cameron, St. Catharines, Ont. It comprises the construction of a diversion weir and of culverts at several points between the present and the old canal, after which a portion of the old canal will be filled in and the space between it and the present canal used as a dumping ground.

THE ENGINEER AND THE PUBLIC.

THE following remarks are extracted from several recent addresses of Walter J. Francis, C.E., of Montreal—one to the Ottawa branch and another to the Calgary branch of the Canadian Society of Civil Engineers, on the 2nd and 9th inst., respectively:—

It is, perhaps, easier to say what an engineer is not than to say what he is. The expression engineer is most difficult to define. Turning to a dictionary it will be found that an engineer is one who practises engineering, or that he is one who schemes or contrives. One of the most eminent jurists of the United States struggled with this problem for twenty minutes—to come to the conclusion that the engineer is a good fellow. To define engineering is about as difficult as to define engineer. It may be presumed that the logical dictionary method would be to say that engineering is the art practised by an engineer. The Institution of Civil Engineers of Great Britain refers to "the art of directing the great sources of power in nature for the use and convenience of man." The Canadian Society of Civil Engineers refers to "the profession of a civil engineer whereby the great sources of power in nature are converted, adapted and applied for the use and convenience of man." Is it any wonder that the public does not understand what we are when we have so much difficulty resulting in trying to say what we are. It would appear that Professor Swain has devised a definition which is, at least, comprehensive. He calls engineering the application of the laws of nature, the principles of mechanics and the materials of construction, to the business of the world.

The classes of engineers were placed by Mr. Dunn, the President of the American Institute of Electrical Engineers, in Boston a couple of years ago, as numbering 27. Later, some individual of a statistical turn of mind isolated 110 distinct species of engineer. Since then four others have been discovered, which gives a factor of safety of two as compared with the famous "57 Varieties."

Much of our difficulty doubtless arises from the peculiar combination of the two words, civil and engineer, which occurred long before the present state of engineering art, at a time when it seemed desirable to separate those who were engaged by the Government in purely military works from the presumably less important number who made their living without attaching themselves to the Ship of State. This word civil has been a great source of haziness for a long time. Doubtless it will disappear in the not-distant future. The great engineering organization already recognizes distinctions even amongst the military engineers.

The word engineer is very much abused. There has been noted with much pleasure the persistent care with which one of the vice-Presidents of the Society always refers to his numerous locomotive drivers as engine-runners or enginemen, either of which terms is very definite and easily comprehended. It is a fortunate thing that the man who drives a street car is satisfied to style himself a motorman, that the driver of an automobile prefers to be known as a chauffeur, and that the aviator does not wish to be called an aeroplane engineer. If the man who runs an engine must be called an engineer, what would you call a man who runs a wheelbarrow?

One of the safest standards for judging what an engineer should be may be taken from the requirements of the highest grade of membership in the three great engineering Societies of English-speaking engineers, the Institution of Civil Engineers of Great Britain, the American Society of Civil Engineers and the Canadian Society of Civil Engineers. All of these recog

nize four principal qualifications, namely, age, education, occupation and professional experience. For full membership the Institution requires one to be at least 33 years of age, the other two have a minimum age limit of 30. All three require a liberal education, while the Institution and the Canadian Society of Civil Engineers consider university graduation a great benefit and the equivalent of several years' experience. Regarding occupation, the requirement is that the candidate must be in active practice and have been engaged in engineering work for 10, 12 or 15 years. The professional experience demanded is ability to design and direct engineering works and having had at least five years of responsible charge of important work, the Institution requiring also that the candidate shall have attained a considerable degree of eminence in the profession. Comment on these requirements would seem to be superfluous. It is practically impossible for a person to attain the requisite experience before reaching the age of 30. Education never made an engineer, but it has made many a good foundation. Occupation and professional experience are essential features. All of the Societies make provisions for young men to enter their ranks and to have advantages while climbing upwards to the highest grade.

Is the Engineer a Professional Man?—The question naturally arises, "What is a professional man?" and we instinctively think of the lawyers, the doctors and the clergymen.

One of the distinguishing features of their profession is a representative governing body. The distinguishing feature of each professional body is its code of ethics. The distinguishing feature of professional men is that their remuneration is independent of the result of their labors. A professional man would then seem to be one who is engaged in mental labor, associated with a recognized governing body directed by a code of ethics and receiving recompense without reference to profits resulting from his work. Judged by this standard alone, the engineer as a whole cannot be classed as a professional man, because many of our greatest engineers are engaged in some form of business, such as contracting, bridge-building, shipbuilding or manufacturing, whereby their remuneration depends on the success or failure of undertakings. In medicine, for instance, if a doctor were to exploit one of his prescriptions for the sake of deriving profit therefrom, he would no longer be considered a member of the profession, notwithstanding the fact that he may still have the same high moral character, the same medical skill and the same interest in the alleviation of suffering. Because he is deriving a profit from the sale of his medicine he is considered to be in business.

It will be interesting to digress for a moment in passing to refer to the positions that the three professions, law, medicine and theology, have attained in the mind of the public. They have, of course, all been at it for centuries. The Inns of Court go back so far that it is difficult to arrive at the true history of the organizations of legal men. The doctors co-operated so long ago that the commencement of their organization seems to be lost track of. The preachers have had very close corporations from the beginning of history. These three professions are examples of the strongest possible kind of close corporation. It is impossible for a man to practice in any one of them without the full consent of the governing body. Indeed, to attempt to practice in some of these fields would be to commit an offence against the law of the land. The strength of the professions of law and medicine in this sense is due in a great measure to two important factors, one, the education of the young men entering the profession, and the other the part played by the older members of the profession as representatives in Parliament. As an example of the influence of the medical profession on the education of the coming generations of doctors, two years ago the Carnegie Foundation sent out too representatives, who paid a visit to, and studied the course given in, all the medical colleges of America. These representatives reported to the Foundation. Since that time 39 medical colleges have closed their doors and every other medical curriculum has been altered.

In theology the lines of denominations are so firmly fixed that the most absolute of all close corporations exist, corporations that have practically absolute control of the most far-reaching of all civil contracts, namely, the marriage contracts. These points are mentioned merely to show the result of the efforts of time and organization.

The position attained by the older professions cannot be attained by engineers in a short time. Law, medicine and theology are as old as the hills. Engineering is a modern art. By the very definition of Professor Swain it will be seen that it was impossible for man to have an art of engineering until he understood the laws of nature and the principles of mechanics. What he knows of these things he has not known long, and probably he knows them still imperfectly.

The above-mentioned engineering societies must be considered as technical societies and not professional societies. The statement that there is only one professional society of civil engineers in America may sound rather novel and improper to many. About three years ago there was formed in New York City the organization known as the American Institute of Consulting Engineers. Since that time similar bodies have been instituted on the Continent, and quite recently in England. The distinguishing characteristics are that the minimum age for admission is 35 years, and that a candidate for membership must be of good personal character and high professional reputation. The qualifications required are higher than those of any of the other engineering socities, and it is expressly forbidden for any member to engage in contracting.

This organization has a very rigid code of ethics, as well as a schedule of fees.

The Relation of Engineers to Each Other.—The code of ethics of the Canadian Society of Civil Engineers may be taken as a reasonable guide for conduct towards a fellow-engineer. It does not require anything more than the respect accorded by doctors to other doctors or lawyers to other lawyers.

The Relation of the Engineer to the Public.—The public seems too prone to consider the engineer a sort of glorified plumber, and we immediately come to the anomalous situation that that same public, while hesitating to attempt to wipe a joint on a lead pipe, would rush in and express the most decisive opinions on larger questions, believing that they know all about the laws of nature and the principles of mechanics.

The daily press is not blameless in its comparative appreciation of engineers. It is frequently observed that four lines or so are given to the reference of some important engineering gathering, while a whole column of the same issue is devoted to a popular story about "a veteran engineer." One reads the column only to find that it refers to the man who operates the throttle-valve on the engine of a river-boat. Such a man is not by any means immune from praise and noteworthiness. It is evident, however, that there is a lack of distinction between those persons represented by the creators of the engine and those represented by a man who operates it.

It is the common public practice for corporations, municipalities, and even individuals, to invite competitive bids for engineering services. Permit an analogy to be made with medical men. Suppose a person were afflicted with a tumor. Then let him send out invitations, far and wide, to surgeons to ascertain their prices, when they can do the work, complete specifications for the operation, and the photograph of the applicant. Having chosen the two lowest bidders, one of whom happens to be the handsomest of the bunch, perhaps, the tumerous individual proceeds to work the two competitors against each other, with the result that the homelier-looking one underbids the pretty one by $3.60 and gets the job.

Then, the native engineers are very apt to be forgotten by the press. Not long ago one of the foremost newspapers of Canada had an article stating that as American engineers had failed in a certain Canadian proposition it had been necessary to call English engineers.

One is apt to think at times that the unfortunate failures in engineering are unduly advertised. For each one failure, there are thousands of successes in engineering. In this regard the engineer as compared with the lawyer, the preacher and the doctor is severely handicapped. In the case of the lawyers on opposite sides in a suit, one of them must necessarily lose. The preachers deal in futures, and nobody has as yet been known to return to tell us about their mistakes. The doctor buries his.

It cannot be denied that the engineer has not yet reached in public and parliamentary life the eminence of the doctor and the lawyer. Give him time, wait until he gets a little older, and it will be found that the engineer will be just as successful in the legislative halls of the country as he has been in the great outside world.

The fact that the remuneration of engineers is steadily increasing shows in a tangible way that the appreciation of the public is growing.

What the Engineer is to Expect of the Public.—The engineer has a right to expect from the public the same consideration as accorded to doctors and lawyers.

The engineer should frown upon competitive prices for engineering services. The stand recently taken by the Institution of Civil Engineers in a letter written last month is a very firm one. It is as follows:—

"The Council have had their attention drawn for some time past to a practice which exists among local authorities, of inviting by advertisement engineers to submit in competition with others their terms for preparing plans and proposals for certain engineering schemes, accompanied then or perhaps at a later stage by estimates of the cost of the works proposed.

"In the opinion of the Council such a proceeding is very undesirable in the best interests of the public authorities themselves and is derogatory to the engineering profession. The Council desire to express emphatically that repugnance with which they regard the practice in question. They have every confidence that the members of the Institution will support them by declining to respond in any way to such advertisements as those alluded to.

"The Council have informed the Local Government Board of their action in making this communication to the Institution."

The engineer has a right to expect the medical and the other professions to refrain from entering the field of the engineer. I doubt if an engineer ever lived who would have the temerity to suggest the course whereby a surgeon should accomplish a certain result.

The engineer has a right to expect his country to prefer him before the engineers of other countries. Where unusual skill or highly specialized advice is necessary, it matters not where it be obtained, but having obtained the advice if necessary, the native engineer should be in a better position to deal with the problem as a whole than the men from outside. Canadian engineers can do the engineering of Canada. The work of Canadian engineers stands before the world as a monument to the ability and integrity of Canadian engineers.

How is the Engineer to Reach the Public?—The question of publicity by an engineer is a somewhat delicate one. Proper and improper methods of soliciting work have recently been the subject of carefully studied discussion, and the consensus of opinion seems to be that dignified and proper publicity by such means as professional cards and the way in which doctors and lawyers obtain their practice is the best course. It is generally conceded that a competent and dignified engineer will not solicit work. He does not need to.

The best way of all to reach the public is by education along broad lines in showing the public what the engineer has done. Too many of us are nothing more than animated slide-rules. Too many of us are narrow-minded. Too many of us think we are so busy that we have no time to take the interest of the true citizen in public affairs. Remember that in life there is more than dollars. Next to the agriculturist, the engineer is the greatest producer in the world. The transportation problems and the questions of communication are all in the domain of the engineer. It is for the engineer to design the conveyance for use on land, on and under water and in the air. The influence of the engineer on the arts and sciences should also be spread abroad. The greatest advance in architecture since the ancient orders was the introduction of steel skeletons and reinforced concrete by the engineer. The great advances in surgery result from the engineers' inventions in instruments, as well as electrical and other devices.

How is the Profession to be Elevated?—The profession is to be elevated by the thorough education of the young man entering it, such education being followed by careful training and long, hard experience.

The profession is to be elevated by the dignity of every engineer and by the perfection of his work.

The profession is to be elevated by co-operation with fellow-engineers and by association with the Canadian Society of Civil Engineers.

GARBAGE INCINERATION.

Incineration is the most efficient, sanitary, and, if properly managed, economical way of disposing of garbage in cities and large towns. Mere dumping in a huge midden is not disposal in the true sense of the word. It is simply an attempt to segregate a nuisance. Burial of rubbish requires a large area of ground and a long haul. It may be suitable for small towns that cannot afford an incineration plant, but it is out of the question for larger centres. Dumping into water should never be permitted except by cities on the seacoast, and only then provided the tides are favorable and the waste material will not be washed back on the shore. Reduction of garbage in "digesters" to remove grease is practised in many United States cities, but the capital required and the operating expenses are high. Moreover, such reduction plants are liable to give rise to foul odors, and many kinds of rubbish, such as bottles, tin cans, broken furniture, cast-off clothing, etc., cannot be disposed of in this manner.

THE TRANSPORTATION PROBLEM IN CANADA, AND MONTREAL HARBOR.

THE following abstracts are from a paper read on April 7th, 1914, at a meeting of the Institution of Civil Engineers of Great Britain. The speaker was Fred. W. Cowie, B.A.Sc., M.Inst.C.E.

The population of the Dominion of Canada is about 8,000,000, and the foreign trade per capita is $125.

The population of Montreal, including the connecting municipalities, is about 600,000, and the foreign trade of Montreal per inhabitant is over $600. As a comparison, England (United Kingdom) has a foreign trade per capita of $125, Germany $67, and the United States $41.

The total land area of Canada is 3,600,000 square miles, so that the density of population is less than two per square mile, as compared, for instance, with thirty-one per square mile in the United States.

It has been stated by trade experts that the difference between the average price received by the producer of Western Canada and the price paid by the consumer of the food products is 33 per cent. For wheat for which the consumer pays $1 the farmer therefore receives 67 cents; 33 cents are paid for transportation and handling, and to the selling organizations. It is equally vital, therefore, to the producers in Western Canada and to the consumers in Great Britain, that this latter percentage should be reduced to the lowest possible figure, so that the farmer may receive the full due for his toil, and the cost of living in Great Britain may not be unduly enhanced.

Another consideration which is of vital interest to Canada is the absolute necessity of collecting by her own people the transportation and selling tolls.

As an illustration, it may be stated that, although in Montreal harbor 60,000,000 bushels of grain were handled in 1913, nearly 100,000,000 bushels of Canadian grain were shipped in the same year through Buffalo in the United States.

The cost of transportation per bushel, from the average point of divergence to the United Kingdom, may be stated, for the various stages, as approximately 18 cents.

For every bushel of grain shipped through Buffalo there is therefore a loss to Canadian transportation and selling organizations of about 18 cents, or for 100,000,000 bushels $18,000,000.

Transportation in Canada.—Even with these striking illustrations it is not easy to fully appreciate what is known in Canada as the "problem of transportation." A comprehensive view of the Dominion and the North Atlantic to Europe is shown in the paper by an original map drawn to scale (Mercator's Projection), showing Canada and the northern half of the United States, with the trade routes to Europe. The main routes are naturally "east and west," and the vast area tributary to the River St. Lawrence is geographically shown.

The "north and south" routes through the United States are principally by rail or by the Erie Canal from Buffalo to American Atlantic ports. The Erie Canal was created by the United States to offset the advantages of the St. Lawrence route. The magnificent railway systems between New York and Buffalo are the most powerful rivals of the "all Canadian" routes.

The opening-up of the vast productive areas of Western Canada, where it has been found that with one-tenth of the cultivable land under crop, 200,000,000 bushels of wheat, and double that quantity of other grains, may be grown, has established, within the last few years, entirely new transportation conditions.

With the tremendous tide of emigration from both Europe and the United States to the new provinces, this production will necessarily increase greatly, and the "problem" is, how to provide the required transportation facilities.

A table of transportation routes from the Canadian West to the United Kingdom is given. This interesting table is worthy of study, as not only present routes are shown but important projected and commenced lines of trade are indicated.

Great efforts are being put forth by the Canadian government and the transportation and other corporations to improve facilities, so as to cheapen and render available Canadian routes; but at the same time similar and extraordinary efforts are being made to improve Buffalo harbor, the Erie Canal, the rail routes, and the harbors of Boston and New York.

In the opinion of the author, who advances striking illustrations and argument, with equal effort, the advantages for future transportation should lie with the St. Lawrence route.

Montreal's Position on the Line of Route.—From the West to Montreal.—The transportation routes in Canada almost all lead to Montreal.

Up to the present the only real rival to the Montreal-St. Lawrence route is the United States route via Buffalo and New York. The western trunk lines of the United States have been improving their "north and south" connections so as to tap the three great western provinces of Canada. These railways provide excellent services to Duluth and Chicago.

A further diversion is made to the United States route at Port Arthur and Fort William. From this twin port at the head of the Great Lakes, the cheapest commercial navigation in the world enables grain and other products to be shipped to Buffalo. Between Buffalo and New York there are several splendid railway systems and the Erie Canal. The new Erie Canal, a modern barge-canal through the state of New York, giving a draught of 12 feet, will soon be completed at a cost, including harbors and damages, which is expected to reach $150,000,000.

The New York and Boston port authorities are at the same time making every effort to improve their harbors, and to provide such attractive facilities as will capture at least a large share of this growing Canadian trade.

By the Canadian routes everything goes by rail direct from the west to Port Arthur. From the twin cities, Port Arthur and Fort William, there are, with modifications, two distinct routes, namely, the "All-Water" route, direct to Montreal, and the "Lake and Rail" route, through Georgian Bay to Montreal.

By the "All-Water" route to Montreal, a distance of about 1,400 miles, vessels are limited by the present Welland and St. Lawrence canals to a draught of 14 feet, or 2,500 tons. An excellent type of vessel has been developed for this service, and the trip from Montreal to Port Arthur and back is made in 14 days.

By the "Lake and Rail" route vessels of 10,000 tons ply between Port Arthur and ports on the Georgian Bay. The Canadian railway companies have established magnificent elevators at Port Arthur and Fort William, and also at several Georgian Bay ports, so that loading and discharging may be carried on with unsurpassed facilities. From the Georgian Bay ports splendid railways are being built to Montreal and existing lines are being improved.

Montreal.—At Montreal harbor the St. Lawrence Canal system and all the great Canadian transcontinental lines centralize. The great Canadian railways—the Canadian Pacific, the Grand Trunk, the Grand Trunk Pacific and the Canadian Northern—are all feverishly improving their terminals at Port Arthur and Fort William, at Georgian Bay ports, and at Montreal.

The Canadian government has commenced the construction of the new Welland Ship-Canal between Lakes Ontario and Erie. This canal, with 800-foot locks and with a possible ultimate draught of 30 to 35 feet, will accommodate the large lake carriers so as to continue to Kingston or Prescott without breaking bulk. This will add greatly to the shipping in Montreal, and will, it is confidently expected, hold the greater part of the Canadian trade to the St. Lawrence route.

Montreal, however, under existing conditions of traffic and accommodation, is almost at the limit of its capacity. With double the present traffic assured within the next few years, it will require a great deal more and better harbor accommodation to meet the demands upon it.

Montreal to the Sea.—With the possible exception of the development of Glasgow there is no more romantic episode in the annals of harbor engineering than the making of Montreal an ocean port. Largely by the faith and energy of Scotch Canadians, following the successful improvements on the Clyde, the River St. Lawrence between Montreal and the sea has been deepened from less than 10 feet to its present depth of 30 feet at the low stages of the river level. During the early summer months the depth is greater, and reaches as much as 38 feet. The minimum width is 450 feet.

Although the author is not now connected with the staff of the River St. Lawrence Ship-Channel, he was continuously engaged upon that great work for twenty-two years, commencing as an assistant and being in charge as superintending engineer for ten years up to 1909. For many years this work has been looked upon as being one of the great successful public works of Canada, and under the Hon. J. D. Hazen, Minister of Marine, the work is now in charge of Mr. V. W. Forneret, B.A.Sc., superintending engineer, who for many years was the author's chief assistant.

The work is all carried on departmentally. The plant is owned by the government, and for its own special work is probably the most complete dredging plant and excavating machinery for submarine rock which is in existence at the present time.

At the present time, with magnificent range lights for each course, with a splendid system of gas buoys and a telephone signal service, navigation is considered very easy and safe by night as well as by day.

The deepening of the channel from 30 to 35 feet at extreme low water was commenced two years ago, and about one-fifth of the work to tidal water is already completed.

The natural fall in the river level between Montreal and Quebec, a distance of 160 English miles, is 29 feet. The maximum discharge of the river during the season of navigation is about 600,000 cubic feet per second, while at the lowest stages of water the minimum is slightly less than 200,000 cubic feet per second.

With the present average slope and velocity of current and average cross-section, the low-water river level and discharge are balanced, with an average current of about 3 miles per hour. This being theoretically correct, it may be considered assured, that if the water supply of the St. Lawrence remains unchanged and the natural cross-section of the river is not enlarged, the present river levels will be constant.

The permanence of the ship-channel and the St. Lawrence route would therefore appear to be well assured.

From Montreal via the St. Lawrence to the open sea the distance is nearly 1,000 miles, and, besides the attraction to passengers of 3 days' sailing in smooth water with beautiful scenery, the strong commercial consideration for water freights into the interior is the incentive to keep pace with increasing trade on the North Atlantic. During the season of seven months the commerce passing through Montreal is nearly 40 per cent. of the total commerce of Canada, and this percentage is increasing.

In 30 years only two ships have been totally lost between Quebec and Montreal, and the occasional groundings, which are well advertised, are not frequent. None of the accidents whatever in recent years has been due in any measure to the ship-channel.

Montreal Harbor.—The First Improvements.—In 1830 the first Harbor Commission was appointed under the authority of the Governor of the Province of Canada, for the purpose of carrying into effect "An Act to provide for the improvement and enlargement of the harbor of Montreal."

In their first annual report the commissioners recorded that they confidently anticipated that the wharves undertaken would be, when completed, superior to any works of the kind in the province, and would enable the City of Montreal to be advantageously contrasted with any other in North America for beauty, solidity, and convenience of approach by water.

This was the first attempt made to improve the harbor of Montreal by a commission. The commissioners had the same faith in the future of the harbor, and courage in undertaking works, which has characterized the administration from 1830 to the present time. The present harbor of Montreal justifies the modest boast of the commissioners of 80 years ago.

Scheme of Harbor Extensions of 1910.—In 1910, the author prepared for the harbor commissioners a comprehensive scheme of improvements, according to which it was proposed to develop the valuable water front and shores of the river, owned exclusively by the Dominion government and held in trust by the harbor commissioners, so as to result in the following revenue-producing features: (*a*) Sites for industries, by making land and improving connections with inaccessible properties; (*b*) the extension, enlargement and improvement of railway termini, giving equal facilities to all Canadian lines for connecting with harbor and industrial points; (*c*) facilities for encouraging and developing industries along the valuable water front.

According to the Board of Consultive Engineers, the items approved were estimated to cost $17,000,000, and this work is now in progress.

This winter condition is a surprise to those who are accustomed to ports open all the year round, but as the Great Lakes and their navigation, amounting to 75,000,000 tons annually, and their great ports are also all closed at the same time, and by the same cause, Montreal harbor does not suffer unduly. The shipping of the St. Lawrence in the autumn is at once transferred to the excellent Canadian ports of Halifax and St. John, and commerce is carried on all the winter as usual with only the disadvantage of the extra rail haulage.

A very full description is given of the physical features of the River St. Lawrence and Montreal harbor.

Construction conditions and types of construction are described and illustrated. They show that although the cost of labor is very high in Canada, this is counterbalanced to a large extent by the use of machinery.

The original "make shifts" for harbor construction are now being followed by modern design. The use of timber and concrete, and the designs to overcome the danger and damage from frost action, are described fully.

Floating Dock, Shipbuilding and Repairing Yard.—For many years the harbor commissioners of Montreal, urged on by the shipping and business interests, have endeavored at various times to solve the problem of the establishment of a dry dock in Montreal harbor.

Negotiations in 1909 with a shipbuilding firm and the final incorporation of The Canadian Vickers, Limited, solved the problem. The harbor commissioners agreed to furnish the site, situated on harbor property, in such a position that nothing would be done to hamper future extension of the harbor. The commissioners undertook to dredge the deep basin and to furnish a site of 30 acres of made land. The rental from the land and the increase in harbor traffic is expected to pay the harbor commissioners the interest on the outlay.

As a result, Montreal harbor has now a floating dock capable of docking the largest vessel trading to the St. Lawrence, at practically no burden on the harbor finances, and there are being established naval construction works capable, in a year or two, of building, in Canada, any vessel from a Dreadnought to a full-sized merchant ship.

This dock was constructed complete at Barrow-in-Furness, and towed across the Atlantic by two powerful tugs, reaching Montreal on 18th November, 1912. The length of the dock over platform is 600 feet, the width over all 135 feet, and the lifting capacity 25,000 tons. On the 18th November, 1912, H.R.H. the Duke of Connaught, Governor-General of Canada, formerly dedicated the new floating dock to the service of commerce and shipping.

The Storage and Handling of Grain.—As grain shipments in Montreal harbor constitute about one-fifth of the total annual freight handled, and as every effort is being made to meet competition so that the greater part of the Canadian grain exported shall be shipped through Canadian ports, special attention is given in this paper to the facilities for the storage and handling of grain.

It is acknowledged that the Montreal equipment is the latest and most successful, as compared with the facilities for the storage and handling of grain at any of the great ocean ports of the world.

As the most characteristic unit of this plant has just been completed, the author, who has had to do not only with designing but also with operating, gives a detailed description of the grain-handling trade, as well as of the design and construction of the plant in Montreal harbor. There is probably no lesson in port-management to be learned that will better illustrate how failure may be turned into success by arranging varied operations under one management and yet so centralized as to cover every requirement of a special trade without disturbing other departments of port business.

Elevator No. 1 was constructed in 1904. It was of the latest design and was placed in the most valuable site on the harbor. It could receive grain by railway wagons or by lake vessels at the rate of 16,000 bushels (400 tons) per hour. Ocean steamships, by moving to the elevator berth, could be loaded at double that rate.

The ocean vessels, however, declined to move to the grain berth to receive grain. It involved tug service, pilotage, etc., and interrupted other operations of loading and unloading, and they desired to ship grain at certain and convenient periods of unloading and loading. Tramp vessels were satisfied, but the proportion of tramps was small. In 1907 the working of this elevator devolved upon the author. The capital cost then amounted to about $1,000,000, the interest account to over $25,000, the operating and maintenance charges to an equal sum. The total revenue for 1907 was about $8,000, and the loss was over $40,000.

The system can store 3,600,000 bushels of grain, can receive about 800,000 bushels (20,000 tons) per day, and can deliver an equal quantity to any of fifteen ocean steamships at their regular berths, and to nine vessels at one time. With it, and with a fleet of six floating elevators for direct transfer, the harbor commissioners received, stored and delivered in 1913 nearly 44,000,000 bushels. The capital expenditure had now reached $4,500,000, but during this season, the first covering the operation of the complete installation, the system paid interest, maintenance, operation and depreciation.

This very complete and costly installation is the result of competition. Its purpose is to keep the trade in Canadian channels, and reduce the cost of transportation. While the Canadian Government and the harbor commissioners of Montreal are encouraging and cheapening transportation, there are those who, rightly or wrongly, are of opinion that improvements for the storage and handling of grain in the ports of the United Kingdom are not advancing in equal measure, so as to result in lower cost to the consumer and better encouragement to the producer. The importation of grain is one of the largest items of the shipping at several of the ports of the United Kingdom. The facilities for the economical handling of grain, and the cheap forwarding of it to the manufacturing mills are, however, far behind the modern successful American and Canadian practice, and even of the growing competitive North Sea ports. There is also a decided lack of such storage facilities as would guarantee food supply, and at the same time regulate shipments and, consequently, prices. In several of the magnificent new dock schemes, where such methods could be installed to apparent advantage, these features, which have been so successful in reducing costs in Canada, are apparently overlooked, although it is felt that, for so extensive a trade, they should receive exceptional attention. Otherwise further encouragement will be given to the United States millers to manufacture Canadian wheat, and ship the flour in convenient packages direct to the bakers, resulting in loss not only to Canadian transportation systems but also to British manufacturers, and further curtailment of the home food supply, to which public attention has been drawn.

The questions of storage and ventilation, and also the cost of modern elevators are dealt with, and the remarkable reduction in insurance rates in modern elevators is referred to.

The floating pneumatic elevator, discharging on to conveyer-belts in culverts leading to a central storage elevator, should be practicable at most of the new British docks. Construction work, labor, machinery, and power being cheaper than in Canada, the tariff charges, allowing for profit, should not be higher than in Montreal for a similar operation. The cost of insurance on grain in modern elevators is exceedingly low; the rate on grain in the Montreal harbors elevators is 20 cents per annum per $100, as compared with $3.20 per $100 in wooden elevators. With such storage facilities owners could store

in large quantities and hold for favorable markets, and the economic results on even a portion of the total imports into the United Kingdom, amounting to about 500,000,000 bushels per annum, would pay in a year for probably one such installation.

Cost of Elevators.—The cost of modern elevators has ranged from 40 cents to $1 per bushel of capacity, so that a million-bushel house costs from $400,000 to $1,000,000. The harbor commissioners' system, with a storage capacity of 5,000,000 bushels, and with its extensive conveyer system providing galleries to nineteen berths, will cost about $5,000,000, or $1 per bushel. Elevators of similar type and working capacity can be built without the conveyer facilities for about 60 to 70 cents per bushel.

A detailed description of the construction of the latest elevator is given in an appendix.

Of importance to engineers and architects and builders is a section of the paper on Vibration Tests of Reinforced Concrete.

Considering the experiments as a whole, it would appear that the effect of the vibration was to increase the tensile and crushing strengths of the concrete, rather than to reduce them. This is probably due to the fact that the vibration had the effect of compacting the concrete, filling the voids more completely, and driving out any air bubbles.

General Organization.—The banks and river-bed making up the area included in the limits of Montreal harbor are owned by the Federal Government of Canada, represented by the Minister of the Department of Marine and Fisheries. Within the limits of the harbor is included the two banks and the bed of the River St. Lawrence for a distance of about 17 miles. The area of land, improved and unimproved, is approximately 350 acres.

By statute the administration and control of this property are entrusted to the harbor commissioners of Montreal, a corporate body having exclusive powers by Act of Parliament for the improvement and management of the harbor, subject to approval by Order-in-Council. Except for police and fire jurisdiction the harbor is quite separate from and independent of the city. The commissioners build and maintain all roads on their territory, do the electric lighting, and have absolute control of traffic.

From absolutely unimproved shores in 1830, the harbor has been developed until now the value of the land, without including the extensive improvements, is much in excess of the bonded debt of about $20,000,000.

The present harbor commissioners are: Mr. W. G. Ross, president; Mr. Farquhar Robertson and Lieut.-Col. A. E. Labelle; Mr. David Seath is the secretary.

Ocean Tonnage.—The number of sea-going vessels which arrived during 1913 was 820, with a total net tonnage of 4,690,535 tons. An equal number of vessels with the same net tonnage departed.

COPPER BEARING STEEL SHEETS.

B. and S. H. Thompson and Co., Limited, Montreal, announce that they are prepared to supply samples and descriptive booklets of Keystone copper-bearing steel sheets. These sheets were placed on the Canadian market last year, and it is claimed by their makers that they have greater [illegible] than ordinary steel sheets and that they are therefore particularly adapted for use in the manufacture of all exposed sheet metal work.

A NEW PATENTED GARBAGE CAR.

As cities increase in size, the disposal of garbage becomes of more and more importance and in connection with garbage disposal, the following points must be considered.

(1) The garbage disposal plant must be located so that it will not be a nuisance to surrounding property. This means that it will often be located some distance from the centre of the city, and too far out to haul the garbage to the plant by horse and wagon.

(2) The receptacles in which it is conveyed must be water-tight to avoid leakage of the material and consequent nuisance on account of the odor.

(3) The receptacles must be constructed so that they can discharge their contents with minimum labor and cost.

For cities located on the sea-coast, the material is generally loaded into barges from the garbage wagons; but for the interior city, this method is not possible, and the garbage disposal plants are usually located some distance out from the city and on a railroad.

A switch is then obtained as near the centre of the city as possible, and the garbage wagons go to this point and dump their loads in large capacity cars which are hauled to the garbage destruction plant. The type of car which has proven most satisfactory for this purpose is shown in the cut. It consists of a large tank with semi-circular bottom and capacity of 1,200 to 1,800 cu. ft. The tank rests on rockers at the ends and at intermediate points on rollers so that it can be dumped and righted with the expenditure of very little power. These cars are built to conform to standard M.C.B. requirements in every respect, and are accepted for transit on their own wheels by any railroad. Large quantities of these cars have been supplied to Cleveland, Columbus, Toledo, St. Louis, and a number of other cities by the Orenstein-Arthur Koppel Company, of Koppel, Pa., who control and have patented the design.

DISCUSSION OF TRANSIT FACILITIES.

An interesting topic and one of great economic importance at the forthcoming International Conference on City Planning, in Toronto, will be the improvement of rapid transit facilities in our growing cities. A paper on "Provision for Future Rapid Transit: Subway, Elevated or Open Cut and their Influence on the City Plan" will be delivered by J. V. Davies, Consulting Engineer, Brooklyn Rapid Transit Company, and will be followed by another paper on "Rapid Transit and the Auto Bus," by John A. McCollum, Assistant Engineer, Board of Estimate and Apportionment, New York City.

An estimate of the water extensions necessary for this season at Fredericton shows a total cost of work that will be about $8,000; while the estimate furnished on sewer extensions approximates a cost of $10,420.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

CONTENTS.

BOOK REVIEWS.

Gear Cutting in Theory and Practice.—By Jas. G. Horner, A.M.I.Mech.E., published by Emmott & Co., Limited, Manchester and London, as one of their "Mechanical World Series;" 391 x xii. pp.; 367 illustrations; size 6 x 9 in.; cloth; price $2 net.

This is a very useful book for the mechanical engineer and shop man. It is practically devoid of technical formulae, the author endeavoring to incorporate the later developments of the art in a reasonably comprehensive manner rather than to enter into a necessarily long theory of design of gear teeth. The association of practice with principles has evidently been his aim throughout and in this he has for the most part succeeded. His illustrations are many and are well chosen, and his writing is of a readily understandable nature.

The book comprises 18 chapters in four sections, the first of which covers the principles of design; the second, methods of gear cutting; the third, machines, including cutters, plainers, milling machines, etc. Section 4, deals with materials, manufacture and strength of gears. An appendix consists of very useful tables for mechanical engineering.

There are several instances where the author does not make himself clear. In one or two cases his terminology is undoubtedly at variance with that which is almost universally accepted. These slips are unimportant, however, and are not misleading to the man familiar with the machinery of gears or the principles of their design. To counteract them he will find a great deal of very useful information with which to supplement his previous knowledge by the later developments in engineering practice.

Roads and Pavements.—By Ira O. Baker, C.E., M.Am.Soc.-C.E., Professor of Civil Engineering, University of Illinois. Published by John Wiley and Sons, New York, Canadian Selling Agents, Renouf Publishing Company, Montreal; 698 pp.; 171 illustrations; size 6 x 9 in.; cloth; price $5.

The second edition of Dr. Baker's treatise on Roads and Pavements is an enlargement upon the previous edition, but the incorporation into it of an additional chapter of over 40 pages on the subject of automobile roads and concrete pavements, and by the bringing up-to-date of the original edition, which will be remembered as having been accepted 10 years ago as an excellent treatise on this subject. In the new edition the concise but comprehensive style of the author is evident throughout. Part 1, deals with country roads, their location, economics of various kinds. It comprises seven chapters. Part 2, contains 14 chapters on street pavements covering economics, design, drainage, foundation, more important kinds and the comparison of them. A chapter is also devoted to sidewalks. In the newly added chapter mentioned above appears a summary of the modern and changed practices which the advent of the motor vehicle has necessitated. It discusses effect of automobiles upon roads; method of suppressing dust; methods of forming a protective covering; construction of bituminous macadam roads and of concrete roads. In the latter various specifications have been summarized. The whole chapter is well condensed and orderly, and adds materially to the value of the book.

Poor's Manual of Railroads for 1914.—Published by Poor's Railroad Manual Company, 535 Pearl Street, New York; 2,052 pp. of text; size 7 x 9 in. This is the 47th annual number of Poor's Standard Manual. It is devoted entirely to steam railroad securities, and is published separately, Poor's Manuals of Public Utilities and of Industrials respectively to be published at a later date.

The special feature this year is the information part given in the manual showing whether or not interest on railroad bonds is payable without deduction for the United States income tax. It contains other new features, including about 500 new comparative and analytical tables, all contributed to assist the investor in forming an opinion of the value of railroad securities. It is needless to say that this manual is the most reliable and carefully compiled work of its kind on the subject of American roads.

Industrial Training and Technical Education. Part 4, of the report of the Royal Commission on Industrial Training and Technical Education, Jas. W. Robertson, Chairman, 770 pp.; 6 x 9 in.; cloth.

This part of the report deals with the inquiry in Canada. The provinces are taken separately. An outline of the educational system of each, provisions for technical instruction, a summary of testimony as to industrial workers, steel, iron and coal, agriculture and agricultural education are divisions typical of the classification of the inquiry.

Canadian Patent Law and Practice.—By Harold Fisher, B.A., LL.B., and Russel S. Smart, B.A., M.E., with an appendix on Canadian Patent Office Practice, by W. J. Lynch, I.S.O.; published by Canada Law Book Company, Limited, Toronto; 478-xxxii. pp.; 6 in. x 9 in., half leather binding; price, $7.50.

There are many ways in which this book will be found of distinct value by not only patent attorneys and solicitors, but by engineers who have frequent occasion to investigate patent claims or regulations respecting them.

The work is divided into 20 chapters, some of them condensed to essentials only, while others go into considerable detail such, for instance, as the sections devoted to infringement, and practice in infringement cases.

The whole question of patent law seems to have been very thoroughly investigated, and although written primarily for the patent lawyer, engineers and manufacturers who are interested in inventions should acquaint themselves of Canadian practice as considered in this book.

An important feature is an appendix by W. J. Lynch, Chief of the Canadian Patent Office, who discusses in detail Canadian Patent Office Practice. The volume also contains copies of standard forms for petitions, specifications, assignments, disclaimers, etc.

The Gyroscope.—By F. J. B. Cordeiro, published by Spon and Chamberlain, New York; 104 pp., illustrated; 5½ x 8½ in.; cloth; price, $1.50.

(Reviewed by A. S. L. Barnes, Hydro-Electric Power Commission of Ontario).

This book is divided into two parts,—"Theory" and "Applications."

The author has a way of making positive statements which arouse in the reader a desire to refute them if possible, and several of them are certainly open to argument. For example, when we are told that the word "torque" is engineering "slang" for "couple," it seems time to raise a protest since the two words are not inter-changeable, the former being the cause and the latter the effect.

Again, it is argued that rotation from right to left should be taken as the positive, or +, direction instead of, as is more usual, the reverse or "clockwise" direction; the reason given being that "in the Northern Hemisphere . . . practically all the motions of nature are to the left—cyclones, heavenly bodies, etc." This question of direction, however, surely depends on the location of the observer; for example, in looking down on the solar system, from an astronomer's point of view, that is, from outside, while considering the North Pole as the top, the author's statement is true, but we are not all astronomers, and it is at least probable that man's universal predilection for what we call right-handed rotation has been due to the fact the apparent direction of rotation of the "heavenly bodies" is in that sense, so that, instead of our clocks and our screws having been made right-handed "by accident," it is much more likely to be traceable to man having had an example of "right-handed" rotation before his eyes throughout the whole period of his existence on this planet—the accident, if there be one, is due to the Creator having arranged, not only the directions of rotations as they are, but also to his having allowed "the greatest population and the highest civilization" to exist on the Northern Hemisphere—had astronomy had its birth in the Southern Hemisphere Mr. Cordeiro would have argued in the opposite sense to what he does now, as then his viewpoint would have been changed and he would have declared that the motions of the heavenly bodies were from left to right.

A considerable portion of the theoretical part of the book is not of direct interest to engineers, as it is devoted to problems of an astronomical nature; in the earlier pages there are, however, several interesting cases of gyroscopic motion treated mathematically which could be readily applied to many engineering problems. In the second part of the book, the writer points out that a train in rounding a curve has two forces tending to de-rail it, the centrifugal action, which is guarded against by raising the outer rail, and also the gyroscopic action of the rapidly revolving, heavy masses of the wheels, which, as is well-known, tends to prevent their being turned out of the plane of rotation. It is asserted that engineers neglect this latter point; if so, they should consider it at once, as the force thus exerted on a long train running at a high speed must be very far from negligible.

Aviation comes in for some remarks, and here it is stated that two motions and two propellers revolving in opposite directions would have the effect of neutralizing the gyroscopic action which is present when only one motion is employed. Makers of aeroplanes might well look into this point as tending to greater flying efficiency.

Following this are descriptions of several practical applications of the gyroscope, such as the Brennan Mono-rail car and the Gyro-compass, etc., which have been described in the technical journals.

Although some little criticism is here given, the book is really interesting, and to anyone dealing with any bodies in which rotational motion plays a part, whether he be an engineer, an astronomer, meteorologist, a designer of guns and projectiles, or even a "sky pilot," in the latest accepted meaning of this term, there are points which, especially if he have a liking for mathematics, will take his attention.

Egyptian Irrigation.—By Sir W. Willcocks, K.C.M.G., F.R.G.S., and J. I. Craig, M.A. (Edin.), B.A. (Cantab.), F.R.S.E., F.R.Met.S., with an introduction by Sir Handbury Brown, K.C.M.G. Published by E. and F. N. Spon, Limited, London, and Spon and Chamberlain, New York. Third edition in 2 volumes; 884 pages, 81 plates and 188 illustrations; cloth. Price, $10.50 net.

To engineers having to do with irrigation, reclamation work and water storage, Egyptian Irrigation presents a very valuable compilation of statistics and details covering the extensive development of the Nile region. The Aswan dam and the Delta Assint, Zifta and Esna barrages, to which Egypt is indebted for its transformation, are known throughout the world for the engineering skill, which their construction has entailed. That "the Egyptian question was the Irrigation question," has been for years a well-known saying, as the influence of irrigation pervades Egyptian economics, politics, social life, agriculture, legislation and even religion.

The work includes the fullest information obtainable of the Nile and its tributaries; together with minute presentations of the problems and their solution, covering some of the most interesting hydraulic questions ever encountered.

Sir William Willcocks, whose engineering work in Egypt dates from 1883, was the author of the first two editions of this treatise. The first was published in 1889, just about the time, according to Milner's "England in Egypt" he, while on an exploration trip for the Minister of Public Works, into Upper Egypt, had occasion to join, and take part in, a Mohammedan thanksgiving service in a mosque at Tahta. Later, as Director-General of Reservoirs, he drew up the designs and estimates of the Aswan dam and Assint barrage. Subsequently he prepared the Cairo drainage project. From 1908 to 1911 he acted as consulting engineer to the Turkish Government and prepared projects for irrigating 3,000,000 acres, and controlling the Euphrates and Tigris. (In connection with this work he is at present in America at the Savannah drainage convention as announced in last week's issue of *The Canadian Engineer*.)

His collaborator, Mr. J. I. Craig, has spent 12 years in Egyptian engineering. He is now Controller of Statistics for the Egyptian Government, and is a distinguished mathematician and meteorologist.

Since the publication of the second edition of Egyptian Irrigation in 1899, all the above-mentioned regulating works, and others both in Upper and Lower Egypt, have been con-

structed, and have been attended or followed by notable results. This new edition completely covers the entire development. It necessarily contains a vast body of facts and figures. Reference to these, however, is facilitated by a system of triple indexing.

Volume I. deals in general with the geology, meteorology, hydrology of the Nile region; the Nile in detail; Basin Irrigation (2 chapters), and Perennial Irrigation (2 chapters). Volume II., has the following chapters: Drainage and land reclamation; the Nile in flood; Engineering details; Barrages; Water storage and flood protection; the Aswan dam; Agricultural; Administrative and legal. Appendices deal with Evaporation; Strength of Egyptian stones and mortars; Salt in various lakes; Discharge diagrams, etc.

The book is not the presentation of the views of one or two men. It contains the opinions of many experts, some of them in direct opposition to those of the author's. As an example, one chapter contains quotations from 10 different experts.

The volumes are well printed and strongly bound. Tables and illustrations are exceptional in their comprehensiveness and clearness. The metric system has been used throughout.

Outlines of Railway Economics.—By Douglas Knoop, M.A., Lecturer on Economics, University of Sheffield. Published by MacMillan and Company, Limited, London, New York and Toronto; 274 pp., 5 x 7 in.; cloth; price, $1.50.

This volume is based for the most part upon a study of the railway industry in Great Britain, although it contains frequent references to railways of other countries, particularly Canada and the United States. Its contents are carefully classified into 21 chapters, each dealing with an important and distinct phase of the application of economic study to railways. Some of these, characterizing the book, are as follows: Application of the law of increasing (and decreasing) returns to railways; Determination of prices under both competitive and monopoly conditions; Fixing of rates and fares, and State regulation thereof; State ownership and management of railways, etc.

In his introductory chapter the author presents the following special reasons for the study of the railway industry:

(1) Railways are of enormous importance in society; on the one hand, transportation has some share, great or small, in the production of all commodities, so that practically all producers and consumers are directly interested in the price of railway services. On the other hand, railways have a great influence on the distribution of population, and are consequently a matter of much social concern.

(2) The railway industry affords illustrations of some of the most interesting problems of price determination; the principle of differential charging can be seen at work in other industries, but nowhere is it so fully acted upon as in the case of railways.

(3) The railway industry, partly owing to its tendency to be monopolistic in character, has been marked out for special attention by the State throughout the world; governments either exercise considerable supervision over railways or actually own them.

Suspension Bridges.—By. Prof. Wm. H. Burr, 1913, published by Messrs. John Wiley and Sons, New York. Canadian Selling Agents, Renouf Publishing Company, Limited, Montreal. 414 pages, 67 text figures and 6 plates. Size, 6 x 9 in., cloth. Price, $4.50 net. Reviewed by David A. Molitor, C.E.

The book comprises eleven chapters and two appendices, devoted to the following subjects:—

Chapter I. deals with an approximate theory of the stiffening truss and the properties of the cable, employing a notation which is not uniform with the other chapters.

Chapter II. treats the statically determinate suspension cable with a three-hinged stiffening truss.

Chapters III. and IV. take up the statically indeterminate suspension cable with continuous and non-continuous straight stiffening trusses, considering the special cases of suspenders absent or present in side spans, using Menabrea's "method of least work." Pages 57 to 122 are practically a translation of pages 5 to 17, of chapter 12, vol. II., part IV., "Der Brückenban," by Prof. J. Melan, in Handbuch der Injenieurwissenschaften. More probably this was taken from the translation given in a "Report on Maximum Span Practicable for Suspension Bridges," 1894, by Major Raymond, Capt. Bixby, and Capt. Edw. Burr. The remainder of chapter IV. is elaborated from the same sources, and pages 175 to 211 are devoted to problems pertaining to the Manhattan Bridge, designed by Mr. Moiseieff.

Chapter V. gives the analysis of the straight stiffening truss, according to the method of deflections, and uses two illustrations applied to the Manhattan Bridge.

Chapter VI. concludes the subject of suspension bridges in the discussion of temperature stresses with applications to the Manhattan Bridge.

Chapter VII. deals with arch ribs by graphics applied to the cases with fixed and hinged ends, with one problem of each class.

Chapter VIII. treats of the arched rib for fixed and hinged ends, by Menabrea's "method of least work," giving an example of the fixed arch. This chapter clearly illustrates the circuitous process of the method of least work when compared with the elegance of the influence line method, according to Mohr, Müller-Breslau, Mehrtens, etc.

Chapter IX. briefly discusses the three-hinged arch rib.

Chapter X. devotes 7 pages to the spandrel braced arch.

Chapter XI. deals with cantilevers by analytical methods. This covers 28 pages of information usually given in standard works, without any numerical applications.

Appendix I. on limiting spans and depths of stiffening trusses, gives conclusions arrived at by Prof. Steinman in 1913.

Appendix II. devotes about 7 pages to formulae for reinforced concrete beams employing a notation radically different from the standard and thus rendering the formulae quite useless until the reader has memorized a notation covering 1½ pages.

As stated in the opening sentence of the Preface, "This book has been written primarily to meet the author's needs in the class room, where the chief requisite is the clear elucidation of general principles in connection with their bearing upon engineering work. The satisfactory accomplishment of such a task is none too easy in the treatment of the more simple statically determinate trusses or other structures, but it is excessively difficult when some statically indeterminate structures are under consideration."

To one familiar with the subject matter treated, it is quite apparent that the author has not achieved his principal aims, "the clear elucidation of general principles," and "to give each main structure a general treatment so as to make one demonstration cover all desired or useful special cases."

The general principles governing all structures involving redundancy have remained entirely out of consideration, and yet these are essential to a clear understanding of any modern methods of analysis, and cover all the general and special cases treated, both of suspension and arch bridges.

No criterion is given by which to judge the nature of any particular structure, that is, to decide definitely upon [illegible] condi-

tions involved. Yet this question alone determines the nature and difficulty of the stress analysis, and depending upon the choice of the redundant conditions, the problem becomes difficult or relatively simple, though the general laws and methods remain the same.

The first important step then would be to classify structures according to their degree of redundancy, and then to apply the general method of analysis for statically indeterminate structures. Without these preliminary steps, the solution in its special form loses its comprehensiveness and the reader fails to grasp the broad principles underlying the analysis.

To elucidate this point more clearly, the general process may be briefly sketched as follows: For any number of redundant conditions, X_a, X_b, X_c, etc., any function of the structure, as a moment M, shear Q or stress S may be expressed by general equations, thus:—

$$\left.\begin{aligned} M &= M_0 - M_a X_a - M_b X_b - M_c X_c, \text{ etc.} \\ Q &= Q_0 - Q_a X_a - Q_b X_b - Q_c X_c, \text{ etc.} \\ S &= S_0 - S_a X_a - S_b X_b - S_c X_c, \text{ etc.} \end{aligned}\right\} \quad \ldots (1)$$

These are applicable to the principal frame, derived from the given structure by removing as many members or external supports X, as may be necessary to convert the given structure into a statically determinate one. The quantities with zero subscripts are, therefore, found as for a beam or truss without redundancy, while the $X's$, which may be moments, stresses, or reactions, represent the unknown redundant conditions. These $X's$ depend upon the elasticity properties of the material and cannot be evaluated by the methods of statics, while all other subscript bearing quantities can be readily found by statics applied to the principal frame.

For every structure there exist as many elasticity condition equations as there are redundant conditions, thus making the problem solvable after evaluating the $X's$ by one of the following methods.

I.—Elasticity condition equations in terms of certain determinable stresses according to Prof. Mohr's work equations, where $l/EF = \rho$, as follows:—

$$\left.\begin{aligned} \delta_a &= \Sigma S_a S_0 \rho - X_a \Sigma S_a^2 \rho - X_b \Sigma S_a S_b \rho - X_c \Sigma S_a S_c \rho + \Sigma S_a \epsilon t l. \\ \delta_b &= \Sigma S_b S_0 \rho - X_a \Sigma S_b S_a \rho - X_b \Sigma S_b^2 \rho - X_c \Sigma S_b S_c \rho + \Sigma S_b \epsilon t l. \\ \delta_c &= \Sigma S_c S_0 \rho - X_a \Sigma S_c S_a \rho - X_b \Sigma S_c S_b \rho - X_c \Sigma S_c^2 \rho + \Sigma S_c \epsilon t l \end{aligned}\right\} \quad \ldots (2)$$

II.—Elasticity condition equations in terms of certain determinable deflections according to Prof. Maxwell, thus:—

$$\left.\begin{aligned} \delta_a &= \Sigma P_m \delta_{ma} - X_a \delta_{aa} - X_b \delta_{ab} - X_c \delta_{ac} + \delta_{at}. \\ \delta_b &= \Sigma P_m \delta_{mb} - X_a \delta_{ba} - X_b \delta_{bb} - X_c \delta_{bc} + \delta_{bt} \\ \delta_c &= \Sigma P_m \delta_{mc} - X_a \delta_{ca} - X_b \delta_{cb} - X_c \delta_{cc} + \delta_{ct}. \end{aligned}\right\} \quad \ldots (3)$$

There will always be as many such equations of the form (2) or (3) as there are redundant conditions X.

Owing to the innumerable values of the variable $X's$ required to solve any case for moving loads, the only practicable solution for statically indeterminate structures, even those of the first degree, is by the method of influence lines as first given by Prof. Mohr. The solution is reduced to its simplest possible form by a judicious choice of the redundant conditions as proposed by Prof. Müller-Breslau, by which certain terms of equations (2) or (3) are reduced to zero, thus saving the laborious solution of simultaneous equations.

However, it is not the writer's purpose to do more than to show the broader aspect of this subject which the author has tacitly passed over, and which is of the utmost value in rendering the subject intelligible.

The complexity of the suspension problem in a general treatise is not so much in the solution of the individual case, as in the innumerable variety of possible and feasible cases which exist. Thus any form of truss, arch or cantilever can be combined with a suspension cable, an eye-bar chain or a braced chain.

The author deals with only three general combinations of cables with straight stiffening trusses; 1, girder, with centre hinge; 2, simple girder on two supports; 3, continuous girders. These comprise merely the ordinary types in use. Prof. Müller-Breslau in his Graphische Statik, treats 17 cases without exhausting the subject.

Little or nothing is said regarding the stresses in the individual members of the stiffening trusses, or of braced arches, except for the two-hinged braced spandrel arch. Yet this is quite an important part of the subject and constitutes the real problem after the redundant conditions are solved.

The questions of economic shape and critical sections of an arch rib are not answered, yet a knowledge of these matters is most essential in procuring practical designs with a minimum af labor. It is the writer's experience also, that the "Method of least work" more properly deserves the name "Method of most labor."

The illustrative problems given are not sufficiently comprehensive to serve as complete examples, leaving a great deal to be supplied by the reader in planning actual computations.

While influence lines are employed to a limited extent, far greater use should have been made of these in the analysis of stresses. For the structures treated are precisely those which should be treated by influence lines in preference to any other method.

The style of the book is of uniform excellence with the Wiley publications, though the full-page plates are poorly drawn.

No bibliography is given, and with very few exceptions, only the names of those offering direct assistance to the author are mentioned.

It is rather difficult to understand why students should devote much time to the study of suspension bridges when there is so much fundamental work crowded out by the already overfilled curriculum. On the other hand, the few engineers who may accidentally have to deal with this subject, will do well to consult those authors who have dealt more exhaustively with statically indeterminate structures in general, and suspension bridges in particular.

PUBLICATIONS RECEIVED.

Temiskaming and Northern Ontario Railway Commission. 12th annual report, for the year ending October 31st, 1913.

Electric Switches for Use in Caseous Mines.—By H. H. Clark and R. W. Crocker, United States Bureau of Mines, Bulletin No. 68, 38 pp., illustrated. A study of methods for preventing switching flashes from igniting gases surrounding the switch.

Specifications for Open-Hearth Steel Cirder and High Tee-Rails, as adopted by the American Railway Engineering Association, and by the American Society of Testing Materials. Issued in pamphlet form by Robt. W. Hunt and Co., Limited, McGill Building, Montreal.

Illinois Water Supply Association.—Proceedings of the 6th meeting of this Association, held at the University of Illinois, March 9th to 11th, 1914, containing reports of committees, papers, discussions and general society affairs. 240 pp., illustrated, 6 x 9 in.; cloth.

Sampling and Examination of Mine Cases and Natural Gas.—By George A. Burrell and Frank Seibert, issued as bulletin No. 42, of the United States Bureau of Mines, 116

pp., illustrated. It takes up the collection and analysis of samples and gives a full description of the apparatus and methods used in the various operations.

Tests on Concrete in Sea Water—Progress report of an investigation made by the Aberthaw Construction Co., and H. L. Sherman, Boston, at the United States Navy Yard, Charlestown, Mass., to determine the effect, both mechanical and chemical, of the action of sea water and varying temperatures upon concrete piers of varying composition. Specimens made and immersed early in 1909 were recently examined. A 36 pp., illustrated booklet discloses the observations made.

Preparation of Metallic Cobalt by Reduction of the Oxide.—By H. T. Kalmus, B.Sc., B.H.D., published by the Mines Branch, Department of Mines, Canada, and covering research on cobalt and cobalt alloys conducted at Queen's University, Kingston, 36 pp., illustrated, describing preparatory treatment, methods and apparatus, and reduction with carbon, carbon monoxide, hydrogen and aluminium at various temperatures. The bulletin forms Part 1 of a series of 6 on the study of cobalt.

Trent Watershed Survey.—By C. D. Howe and J. H. White, with an introductory discussion by B. E. Fernow, Dean, Faculty of Forestry, University of Toronto. Published by the Committee on Forests, Commission of Conservation, Canada. 156 pp., illustrated, size 6 x 9 in.; cloth.

This is a report on the conditions in the Trent Watershed and recommendations for their improvement. It outlines the procedure of the survey, its results, etc. One section of the book is devoted to physiographic and forests conditions, including drainage, topography, geology, soils, etc., and a discussion of the financial losses due to forest fires. Another section is devoted to the mechanical and industrial conditions covering farming, lumbering, tourist traffic and social conditions. The book is accompanied by five appendices.

Conservation of Coal in Canada.—By W. J. Dick, M.Sc., Mining Engineer, published by the Committee on Minerals, Commission of Conservation, Canada. 212 pp., 6 x 9 in., illustrated with photographs, maps and diagrams; cloth.

In his report Mr. Dick reviews a full investigation of the coal situation in Canada. Its dependence on the United States for its supply of anthracite coal is one of many points strongly brought out. The development of electric power in the lignite fields of Western Canada is recommended. The manufacture of coal briquettes in other countries is described in detail and the methods adopted to conditions in Canada are indicated. Comparisons are made between the beehive ovens and the by-product ovens for the coking of coal and the economies effected by the latter over the former are clearly presented. Descriptions are given of the principal coal mines in Canada.

The book will be found of great value, not only to those directly engaged in coal mining, but to all who are interested in the economic development of a country.

Good Roads Year Book, 1914.—J. E. Pennybacker, editor, published by the American Highway Association, Washington, D.C., 500 pp., illustrated, 6 x 9 in.; cloth; price $1.

The 1914 Good Roads Year Book is very comprehensive in its collection of data for road men of the United States. It is issued annually by the Association as part of its campaign throughout the country for an adequate system of improved highways. A considerable portion of the volume is devoted to state aid and local road legislation, digests of various road, automobile and convict laws, etc. It contains a complete list of patents issued in 1913 pertaining to roads; a list of bulletins, circulars and documents published in the interests of road builders; a reference list of papers, addresses and magazine articles published in 1913 on the subject of roads. It synopsizes the academic courses in highway engineering of the various universities and colleges, and catalogues the various road associations. The work in different states and the progress of road improvement are featured, while a chapter deals with the important events in the road movement during 1913.

CATALOGUES RECEIVED.

Welding and Cutting Plants.—A 16 pp. catalogue of equipment for acetylene welding issued by Waterhouse Welding Co., Boston, Mass.

Air Compressors.—A 48 pp. leaflet issued by the Canadian Ingersoll Land Co., Montreal, outlining some advantages in their Class "N" compressors.

Aneroids.—A small catalogue circulated by the Topley Co., Ottawa, descriptive of watch and pocket aneroid barometers of "Tycos" make.

Ironclad-Exide Battery.—A sketch of the development of this type of battery in a 24 pp. booklet issued by the Canadian General Electric Co., Toronto.

Cranes for Wharves and Docks.—A pamphlet illustrating typical uses of Demag Cranes, issued by the Deutsche Maschinenfabrik A-G Duisburg, Germany.

Duntley Electric Tools.—An 8 pp. bulletin of Chicago Pneumatic Tool Co., describing portable drills, grinders, spike drivers, etc., for street and interurban railway use.

Mining Tools.—Bulletins Nos. 152-3 and 4 of the Chicago Pneumatic Tool Co., Limited, illustrating their drills, sinkers and stopers, together with the accessories for each.

Railway Motor Gears and Pinions.—20 pages descriptive of forged, solid and split cast-steel gears, pinions, etc. Circulated by the Canadian General Electric Co., Toronto.

Aston Fans.—A 24 pp. illustrated catalogue issued by Veritys, Limited, London, E.C., dealing with the Aston range of ceiling, desk, bracket, ship, railway and saloon fans and blowers.

Small Direct Current Generators.—Bulletin No. A-4188, descriptive of type CVC small, belted, direct current generators; illustrated, 12 pp., issued by Canadian General Electric Company, Toronto.

Montezuma Asphalt.—A beautifully illustrated booklet of 56 pages, issued by the Warner-Quinlan Asphalt Co., New York, describing the qualities and illustrating many streets and roads upon which Montezuma asphalt has been used.

"Steele" Buildings.—A bulletin issued by the William Steele and Sons Co., engineers and contractors, Philadelphia, illustrating a large group of industrial buildings in the design and construction of which that company has had to do.

Chain-Blocks.—A 4 pp. pamphlet illustrating and describing the Morris travelling spur gear chain-block of different types showing saving of headroom due to special design, issued by the Herbert Morris Crane and Hoist Company, Toronto.

Pneumatic Appliances.—An 80 pp. catalogue of air compressors, air hoists, air cranes, pneumatic and hydro-pneumatic elevators, trolleys and trolley systems, and sand blasts fully illustrated, issued by the Curtis Pneumatic Machinery Co., St. Louis, U.S.A., as catalogued No. 62.

Dudbridge Gas Engines.—These types of variable admission gas engines and of gas producing plants are described in a 28 pp. illustrated catalogue issued by Dudbridge Iron Works, Limited, Stroud, England. It shows diagrammatically the construction of the various types and parts, and contains tables of dimensions of capacities, speeds, weights, etc.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page 90, a directory of such societies and their chief officials.

OTTAWA BRANCH, CAN. SOC. C.E.

The closing meeting for the year of the Ottawa branch of the Canadian Society of Civil Engineers was held on Thursday evening, April 23rd.

Mr. C. A. Magrath, C.E., Member of the International Joint Commission and Chairman of the Ontario Highways Commission, gave a short address on "The Engineer and His Profession."

BRITISH COLUMBIA ASSOCIATION OF LAND SURVEYORS.

The British Columbia Association of Land Surveyors has announced the following successful candidates as a result of recent preliminary examinations; G. V. Atkins, R. R. Browne, F. H. Blunt, C. Carswell, G. C. Dunsford, C. N. Dean, G. A. Earle, E. D. Fort, A. B. Fraser, G. F. Heaney, A. D. C. Herne, L. Held, J. L. L. Johnston, W. M. Myers, J. A. McCulloch, J. D. Slaven, F. W. Stevens, N. T. Townsend, R. P. Thomson, and R. S. Wood.

"SUBAQUEOUS TUNNELLING."

This was the subject of a paper read on the evening of April 23rd by Paul Seurot, C.E., chief engineer of Jacobs and Davies, Montreal, at a general meeting of the Canadian Society of Civil Engineers.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Diven, 47 State Street, Troy, N.Y.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9-13, 1914. J. E. Pennybacker, Secretary, Colorado Building, Washington, D.C.

AMERICAN PEAT SOCIETY.—Eighth Annual Meeting will be held in Duluth, Minn., on August 20, 21 and 22, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

INTERNATIONAL CONFERENCE ON CITY PLANNING to be held in Toronto, May 25-6-7, 1914, in charge of the Commission of Conservation. Secretary, James White, Ottawa.

CANADIAN FORESTRY ASSOCIATION.—Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal.

CONVENTION OF THE AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—To be held in Boston, Mass., on October 6th, 7th, 8th and 9th, 1914. C. C. Brown, Indianapolis, Ind., Secretary.

PERSONALS.

J. A. SKERTCHLY, an English mining engineer, is visiting British Columbia to report on gold properties.

GEO. W. CRAIG, City Engineer of Calgary, recently delivered a very interesting and attractive lecture on city planning in that city.

W. S. HARVEY has discontinued his connection with the city of Lethbridge as its acting city engineer, owing to its having adopted commission control of civic affairs. Mr. Harvey is at present in Eastern Canada.

J. W. EVANS, of Belleville, has recently been appointed city engineer of that place, to fill a vacancy of over a year's standing. Mr. Evans, who is president of the Tivani Steel Company, of Belleville, was previously associated with the Bay of Quinte Railway as engineer.

FREDERICK W. COWIE, chief engineer of the Montreal Harbor Board, was recently awarded the Telford gold medal by the Institution of Civil Engineers of Great Britain for his paper, entitled "Transportation Problems in Canada and the Montreal Harbor," read on April 7th. His paper appears in extract form in another part of this issue.

G. N. GUEST, A.M.I. Mech. E., M.I.H.V.E., director of Hollings and Guest, Limited, of Birmingham, England, engineers and manufacturers of hydraulic presses, pumps, accumulators, etc., will visit Canada at the end of May. Mr. Guest will tour the country thoroughly, visiting all the principal towns and cities.

F. A. YERBURY, M.I. Mech. E., manager of the Heaps Engineering Company, Limited, Vancouver, B.C., has resigned and expects to return to England about the end of May. Mr. Yerbury has been in Canada for a number of years. He was formerly manager of the Canadian Boving Company, and while with that firm he introduced the Diesel engine into Canada. Mr. Yerbury will devote his time to inspection work throughout Europe for Canadian and American firms, also reporting on European machinery, methods and progress.

OBITUARY.

As the result of the capsizing of a small boat in the Fraser river, near Lytton, B.C., Messrs. E. T. Shaw, R. M. Horton and H. Burniston, three engineers on Canadian Northern Railway construction, were drowned last week. Mr. Shaw was a son of Mr. H. S. Shaw, of Ottawa, and was division engineer of that section.

The death is announced at Burlington, Ont., of Mr. William White, whose connection with engineering as a contractor is known to many. Mr. White carried out a number

of contracts for the Government, among them being the timber works at Sault Ste. Marie new locks, and the C.P.R. trestles on the north shore of Red Sucker Cove. He built piers at Port Colborne and many other places, also many bridges throughout Ontario.

The death occurred on April 19th of Alfred Noble, C.E., a very prominent member of the engineering profession in New York. His career was a most interesting one, and typical of that of many great men of the profession who rank as nation-builders. Among his many activities in engineering work were the following: From 1868 to 1870 he was assistant engineer on river and harbor work on the Great Lakes. From 1870 to 1872 he was in charge of improvements on St. Mary's Falls canal and St. Mary's river. During this time the first great masonry lock at the Sault, then by far the largest canal lock in the world, was built. On completion of this work he became resident engineer on the construction of an important bridge at Shreveport, La., over the Red River. From 1883 to 1886 he was general assistant engineer, Northern Pacific R.R. From 1886 to 1887 he was resident engineer on the construction of the Washington bridge over the Harlem River; at that time the largest arch bridge in existence. From 1887 to 1894 he was resident engineer on the construction of several bridges over the Mississippi at Memphis and Alton, over the Missouri at Bellfonton and Leavenworth, over the Ohio at Cairo. He was appointed a member of the Nicaragua Canal Board, which visited Central America and examined the route of the Nicaragua Canal, and also the Panama Canal.

In 1899 he became a member of the Isthmian Canal Commission, which was charged with the selection of the best canal route across the isthmus, and it has been substantially on the route selected by this Commission that the Panama Canal has been constructed.

In 1905 he was appointed a member of the International Board of Engineers to recommend whether the Panama Canal should be constructed as a sea-level or a lock canal. This Board consisted of thirteen members, of whom five were nominated by foreign countries. Mr. Noble was one of the minority of five Americans who recommended the adoption of the lock-level plan. Their views were adopted by the Government and the Canal has been built in accordance with their recommendations.

In March, 1907, he was one of the three to visit the Panama Canal to investigate the conditions regarding the foundations of some of the principal structures. Mr. Noble was continuously identified with the Canal project and deserves much credit for the solution of its engineering problems.

In July, 1897, he was appointed a member of the United States Board of Engineers on Deep Waterways, which made surveys and estimates of cost for a ship canal from the Great Lakes to deep water in the Hudson River. In November, 1901, the city of Galveston, Texas, appointed Alfred Noble, along with Henry C. Ripley and General Robert, as a Board of Engineers to devise a plan for protecting the city and suburbs from future inundation. From 1902 to 1909 Mr. Noble was chief engineer of the East River Division of the New York extension of the Pennsylvania R.R., and was in entire charge. Since 1909 he engaged in general practice as a consulting engineer. Probably the most important work dealt with was in relation to the dry docks built for the United States Government near Honolulu. He was also for a time consulting engineer to the Quebec Bridge Board, to the Board of Water Supply, New York City, and to the Public Service Commission of the State of New York.

He has been Past President of the Western Society of Engineers, American Society of Civil Enginers, and American Institute of Consulting Engineers, and an Honorary Member of the Institution of Civil Engineers of Great Britain.

Coast to Coast

Regina, Sask.—A considerable reduction in power rates will probably go into force in Regina within the near future, the civic utilities committee having decided to grant various concessions in the interests of the power user.

Toronto, Ont.—It is reported that an agreement has been effected between the G.T.R. and C.P.R. companies in connection with plans for the Toronto Union Station. These will be submitted to the Dominion Railway Board about May 15. The matter of the viaduct construction has not been finally decided, and will be given later consideration. The cost of the Union Station is estimated at between $12,000,000 and $15,000,000, and that of the viaduct at $3,000,000.

Ottawa, Ont.—The Railway Commission has considered the proposition of the building of the proposed "All Red Line Railway" with a total projected length of 3,270 miles, and has cut it down to a line of but 1,000 miles in length to run from Cape St. Charles on the Labrador coast, to the city of Quebec. The name of the railway was changed to "The Labrador, Quebec and Southern Railway," and the capital stock was reduced from one hundred millions to ten millions. The line, as now authorized, will run west from Cape St. Charles to the Peribonka River, 600 miles; then through the valley of the Peribonka River to a point on Lake St. John, 200 miles further, and then on to the city of Quebec.

Montreal, Que.—The Montreal board of control for the present fiscal year has voted sums amounting to $2,789,907 for public works which have been recommended by Chief Engineer Janin. Of this amount $1,500,722 is to be expended on pavements, $915,545 on sewers and $373,640 on waterworks. The sewer allowance is divided as follows: $31,345 for the East division, $639,500 for the West division, and $244,700 for the North division. The amount for paving is divided as follows: $387,410 for the North division, $621,254 for the West division, and $492,057 for the East division, and the appropriation for the waterworks department is to be used as follows: main pipe $125,000, new services in all sections of the city $65,000, hydrants $27,000, meters $30,000, pipes to relieve strain on present pipes $86,175, and $40,465 for the cost of installing pipes.

Winnipeg, Man.—The season's programme of railway construction in Manitoba, Alberta and Saskatchewan has been definitely decided. The C.P.R. will proceed with the grading which is being done on the 15-mile extension of the Moose Jaw south-west branch beyond Expanse, and will also lay steel upon the same. Also grading will be done on a further 25-mile extension of the line proceeding from Sterling East, though steel may not be laid this year. The C.P.R. will also proceed with grading operations as follows: 72 miles on the Monitor-Kerr Robert line, 25 miles Suffield south westerly, 87 miles on the line running west of Weyburn, 25 miles on a line running north westerly from Coronation, and 126 miles on the line from Bassano easterly. The G.T.P. operations will be largely confined to the branch into Prince Albert from Young, Sask., and the track laying on the Brandon branch in Manitoba. The main line in British Columbia will be completed. On the C.N.R., construction work will be done on the Peace River line from Onoway on the main line north-westerly; also on a line on the north side of the Saskatchewan River extending from Oliver to meet the branch running west from North Battleford. Work will be in progress on the Calgary-Lethbridge branch, on the Elrose to Alsack branch on the Gravelbourg-Swift Current line, on the extension of the Thunder Hill branch, and on the branch from Wroxton to Yorkton.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21632—April 11—Approving location C.N.O.R. station grounds at Lac a Travers, mileage 140.8 from Ottawa, Division "E," Twp. White, Dist. Nipissing, Ontario.

21633—April 11—Approving, subject to terms of consent of Twp. of Verulam, location of platform and shelter of C.P.R. (Lindsay, Bobcaygeon and Pontypool Ry.) at mileage 36.0, Bobcaygeon Sub. Div., in Lot 13, Con. 7, Tp. of Verulam, Co. Victoria, Ont.

21634—April 14—Reporting to Governor-in-Council for sanction By-law No. 13, approving "General Train and Interlocking Rules," for observance by officers and employees of Dominion Atlantic Railway Company, in operation of its railway.

21635—April 14—Authorizing C.L.O. and W. Ry. (C.P.R.) to take, without consent of owner, certain lands in town of Oshawa, for purpose of affording access to diversion of Albert Street, said town.

21636—April 14—Authorizing C.P.R. to use bridge No. 18.7 on St. Gabriel Subdivision, Eastern Division.

21637—April 14—Authorizing C.P.R. to operate over bridge No. 11.3, Standbridge Subdivision, Eastern Division, Que.

21638—April 15—Approving location Pacific and Hudson Bay Ry. from Bella Coola Harbor to Hagensborg, B.C., mileage 0 to 10, Coast Dist.

21639—April 14—Authorizing Lake Erie and Northern Ry. to construct bridge over Western Counties Canal, station 3.00, at Brantford, Ontario.

21640—April 8—Authorizing T.H. & B. Ry. to take certain lands situate in Twp. Pelham, Co. Welland, Ont., for purpose of providing two or more team tracks upon such lands.

21641—April 15—Authorizing C.N.R. to cross and divert public highway on S.W. ¼ Sec. 19-10-30, W. P. M., mileage 76, Kipling Subdivision.

21642—April 14—Authorizing C.N.R., at its own expense, to construct and maintain a highway crossing over its railway on Second St. North, in S.E. ¼ Sec. 1-47-6, W. 3 M., Townsite of Leask, Sask.

21643—April 14—Directing that, within 60 days from date of this Order, G.T.R. install stop blocks on sidings on its line at east side of Cherry Street, Toronto, Ontario.

21644—April 9—Authorizing, subject to terms contained in paragraphs 1 and 2, Bylaw No. 9 of Town of Goderich, G.T.R., to construct siding into premises of American Road Machine Co. of Canada, Limited.

21645—April 14—Authorizing G.T.R. to use and operate bridge No. 257, mileage 25.25, 13th Dist. in Town of Milton, Ont.

21646—April 14—Amending Order No. 19646, dated May 16th, 1913, by striking out all words after word "Caution," in fifth line of operative part of Order, and substituting therefor following, namely: "All trains must come to a full stop at that semaphore and then proceed to the home semaphore and there be governed by the rules governing the operation of interlocked signals."

21647—April 16—Approving revised location G.T.P. Branch Lines Co., Battleford Branch, through N.W. ¼ Sec. 4-43-16, W. 3 M., Sask.

21648—April 15—Approving revised location G.T.P. Branch Lines Co.'s station at Coalspur, mileage 35.8, Alberta Coal Branch, in Sec. 33-48-21, W. 5 M., Alberta.

21649—April 16—Amending Order No. 21537, dated March 23rd, 1914, by striking out figures and letters "19th" [illegible] second line of description of bridges, under heading "District," and substituting therefor figures and letters "20th."

21650—April 15—Authorizing C.N.O.R. to construct bridge over Raimbault Creek, Parish St. Laurent, Co. Jacques Cartier, Que., mileage 48 from Hawkesbury; and rescinding Order No. 19657, dated June 21st, 1913.

21651—April 15—Approving location C.N.R. extension of Swift Current Line through Tp. 15-10 and 12, west 3rd, Meridian, Sask., mileage 124.96 to 142.53.

21652—April 17—Authorizing C.P.R. to construct spurs for F. A. Fish, from a point on easterly limit of right-of-way Main Line, mileage 26.62, Orangeville Subdivision, Ont. Div. in Lot 14, Con. 3, west of Hurontatio St., Township of Caledon, Co. Peel, Ont.

21653—April 17—Directing that, within 30 days from date of this Order, G.T.P. Ry. re-appoint station agent at Zelma, Sask.

21654—April 18—Authorizing C.P.R. to construct road diversion in Sec. 22-36-11, W. 4 M., Alta., and construct, by means of grade crossings, tracks of Swift Current Northwesterly Branch line across eleven (11) highways, mileage 0.0 to 13.0 of said Branch Line.

21655—April 16—Authorizing, subject to terms of resolution, Esquimalt and Nanaimo Ry. to construct siding to property of B. C. Pottery Co., at Esquimalt, B.C.

21656—April 16—Relieving G.T.R. from providing further protection as crossing of St. Patrick St., village of Port Dover, Ontario.

21657—April 17—Granting leave to Hamilton Cataract Power, Light and Traction Co., Limited, to erect, maintain and place 2,400-volt overhead distribution circuit over G.T.R. branch line at Ferguson Ave., north of Barton St., Hamilton, Ont.

21658—April 15—Approving and authorizing, subject to condition that company keep its employees off sides of cars on freight shed side, clearances as shown on plan of an overhead platform runway to serve tracks of T.H. & B. Ry. on north side of Forest Ave., Freight House, city of Hamilton, Ont.

21659—April 18—Authorizing C.N.O.R. to construct across Castle Crescent Road in Lots 36 and 37, Con. 3, F. B., Tp. York, Co. York, Ont., by means of structure carrying highway over railway.

21660—April 17—Authorizing C.N.R. to cross and divert two (2) highways on Maryfield Branch, Sask., namely,—South Road Allowance between Secs. 7 and 8-26, W. 2 M.; and Highway between Secs. 19-5-27, W. 2 M., and Sec. 24-5-28, W. 2 M.

21661—April 16—Authorizing Montreal and Atlantic Ry. Co., to construct siding for Bedford Manufacturing Co., Bedford, Que., from point on westerly limit of right-of-way, mileage 11.16, Stanbridge Subdivision, thence southwesterly across Lots Cadastral Nos. 1315, 1314, 1313, 1310, 1304, 1302 and 1303, Rge. 7, Tp. Stanbridge, Co. Missisquoi, Quebec.

21662—April 16—Authorizing Western Canada Power Co., Limited, to construct spur from point on main line, running through Langley Indian Reserve No. 2, crossing a highway in the Mission Dist. Mun., to connect with trestle in the Stave River, B.C.

21663—April 15—Authorizing Montreal and Atlantic Ry. to construct spur for B. R. Stevens, town of Bedford, Que.

21664—April 17—Authorizing C.P.R. to construct, at grade, tracks of wye at mileage 230.0 on Weyburn-Stirling Branch, across road allowance between Secs. 8 and 17, Tp. 8, Rge. 18, W. 3 M., Sask.

21665—April 17—Authorizing C.P.R. to construct alterations and extensions to tracks at Hardisty St., Fort William, Ont.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

PROPOSED T. & N. O. TERMINAL ON JAMES BAY

As outlined in an address to the Toronto Branch, Canadian Society of Civil Engineers, March 26th, 1914

By J. G. G. KERRY,

Consulting Engineer, T. & N. O. Ry. Commission; President Kerry & Chace, Limited, Toronto

[The subject matter of this article consists of a general review of the engineering work that has been done up to date preparatory to the establishment of a railway terminal on the shores of James Bay. It has been gathered together on the direct instruction of the Commission that has charge of the operations of the Timiskaming & Northern Ontario Railway; and it is good evidence of the forethought shown by the Commission in preparing for the carrying out of a project that must shortly be of great public importance. Mr. Kerry states that the work of preparing this information has been entirely under the direction of the Chief Engineer for the Commission, S. B. Clement, B.A. Sc., M. Can. Soc. C.E., and his staff, who are entitled to much credit for the careful and thorough manner in which the necessary data connected with the project has been gathered together.—EDITOR.]

THE construction of the Timiskaming and Northern Ontario Railway was commenced about the year 1900, the enterprise being undertaken by the Provincial Government of that date in a somewhat blind compliance to the popular demand that a very definite effort should be made to open up the large and unknown area of land that lay to the north of the main line of the Canadian Pacific Railway and between the north shore of the Great Lakes and the south shore of Hudson's Bay. Almost simultaneously, the Provincial Government sent out a number of exploring parties throughout this area. These parties were in charge of various members of the Ontario Association of Land Surveyors, and from their reports the province first learned of the existence of that large area of arable land that is now known as the Clay Belt, and shown in Fig. 1.

Fig. 1.

The importance of this so-called Clay Belt, not only to the Province of Ontario but to the Dominion of Canada at large, cannot be over-estimated. A study of the geographical distribution of our population at the present time will show that it consists of one large and rapidly growing unit which is located entirely to the west of the line of Lake Winnipeg. A second and larger unit is located entirely to the south and east of a line joining Orillia and Pembroke. The district lying between these two lines, with the exception of such towns as North Bay, Sudbury and Port Arthur, may be said to be entirely unsettled; this was absolutely true little more than 10 years ago, and in large measure remains true to-day. A possible result of the existence of so definite a cleavage in the settlement of the Dominion is the growth of a distinct west and a distinct east. From a national point of view this, more than any other one thing, is what we all desire

to prevent and no effort should be spared that will tend to keep this possibility from becoming a reality.

Examining a map, such as Fig. 1, upon which the outline of the Clay Belt is marked, it will be seen that this Belt, which consists of most fertile land, stretches almost half way across the unsettled area which at present divides the Dominion. The speaker, therefore, regards the work of the commission in opening up the Clay Belt for settlement as possibly the most important national work now in progress in Canada.

Other organizations are also active in this work of development; the Algoma Central Ry. is building in from the south and west; the National Transcontinental Ry. and the Canadian Northern Ry. are traversing the Belt from west to east. The next work of importance would, therefore, appear to be the establishment of an outlet to the north and the establishment of a rail connection with the only ocean coast line within the confines of the Province of Ontario. With such an end in view the commission has directed the carrying-out of the investigations that are discussed in this paper.

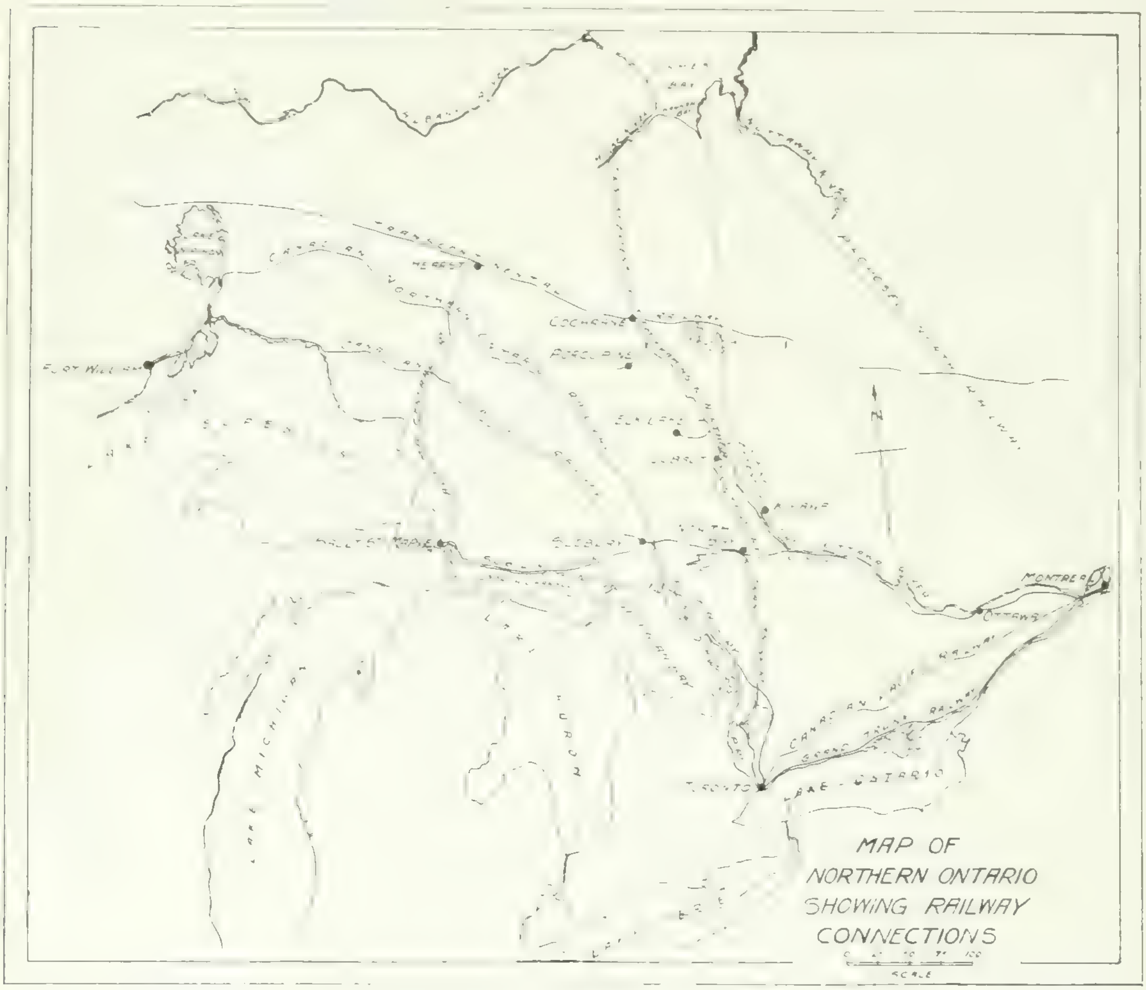

Fig. 2.

The most attractive location for the proposed terminal so far as present information goes, is at the mouth of the Moose River, as shown in Fig. 2, and this point may be referred to as Moose Harbor. It may be remarked that by far the larger portion of the Clay Belt is drained by the tributaries of the Moose River and that the natural movement of traffic will be along the line of these tributaries with a natural point of concentration at the harbor. Geographically speaking, Moose Harbor is not an isolated point and does not lie in an extreme corner of the possible confines of civilization. If on Fig. 1 a half circle is drawn with the harbor as centre it will be found that, without very material change of radius, Winnipeg, Port Arthur, Toronto, Ottawa, Montreal and Quebec can be reached, and it may reasonably be expected that in the not-distant future a commercial centre of some importance will exist near the harbor, and that this centre will transact business directly and independently with each of the cities that have just been mentioned.

A journey from Toronto to Moose Harbor after the completion of the railway extension will not be an arduous undertaking The distance can readily be run within 24 hours, and, as a matter of illustration, the run may readily be compared to the present journey from Montreal to Chicago, or from Toronto to Port Arthur; in each case the distance between the points mentioned is rather greater than the distance from Toronto to Moose Harbor will be, this distance being roughly estimated at 670 miles.

The enterprise of extending the Timiskaming and Northern Ontario Railway to the Bay must be regarded as one of colonization and development; it is not possible to prove from statistics of present traffic that the undertaking will be a commercial success, the simple fact being that no traffic at present exists, although there is every reason to believe that natural resources abound from which an important traffic can be created.

The tributary district to the railway will consist not only of the Clay Belt, but also of the well-defined area of clay lands lying along the shores of James Bay, and geologically known as the Coastal Plain. The soils of this Plain bear much resemblance to those of the Clay Belt, and their development presents in a larger degree the same problems that have to be dealt with in the development of the Clay Belt. Where satisfactory means of drainage exist, the growth of the various species of northern timber proves the fertility of the soil, but the geologists regard the whole district, and particularly the Coastal Plain, as being of very recent creation, placing the period of its elevation above sea level at not more than 10,000 years. The drainage system is, therefore, quite imperfectly developed and large areas of land are buried under muskeg and

moss. The condition is indeed very similar to that which exists on the prairies to the east of Winnipeg, the lands being so flat-lying that their slope is not sufficient to provide for the quick discharge of the melting snows in the spring and the formation of muskegs and swamps naturally follows. The natural slope of the lands is, however, sufficient to enable the engineers of the future to design and construct drainage works on a comprehensive scale that will be perfectly satisfactory in their operation, and with the construction of such works practically the entire area of the district will become available agricultural land.

Much of the district is already efficiently drained by the natural watercourses, and the colonizing energy of the province is for the present being concentrated on the settlement of these lands. In general, such lands carry a healthy growth of spruce wood of sufficient size to be valuable as raw material for pulp and paper mills. Intelligent development of such lands, therefore, provides work for the settler both in summer and in the winter. The clearing-up of the lands is, comparatively speaking, easy work, and the timber as it is cut finds a ready market.

The tributaries of the Moose River have direct courses on their way to the Bay and a relatively heavy fall per mile. As a consequence, numerous sites are found where water power can be cheaply developed, and one of the early industries of the district will be the manufacture of pulp and paper. This has been already undertaken on a large scale at Iroquois Falls which itself is not distant more than 200 miles from the Bay.

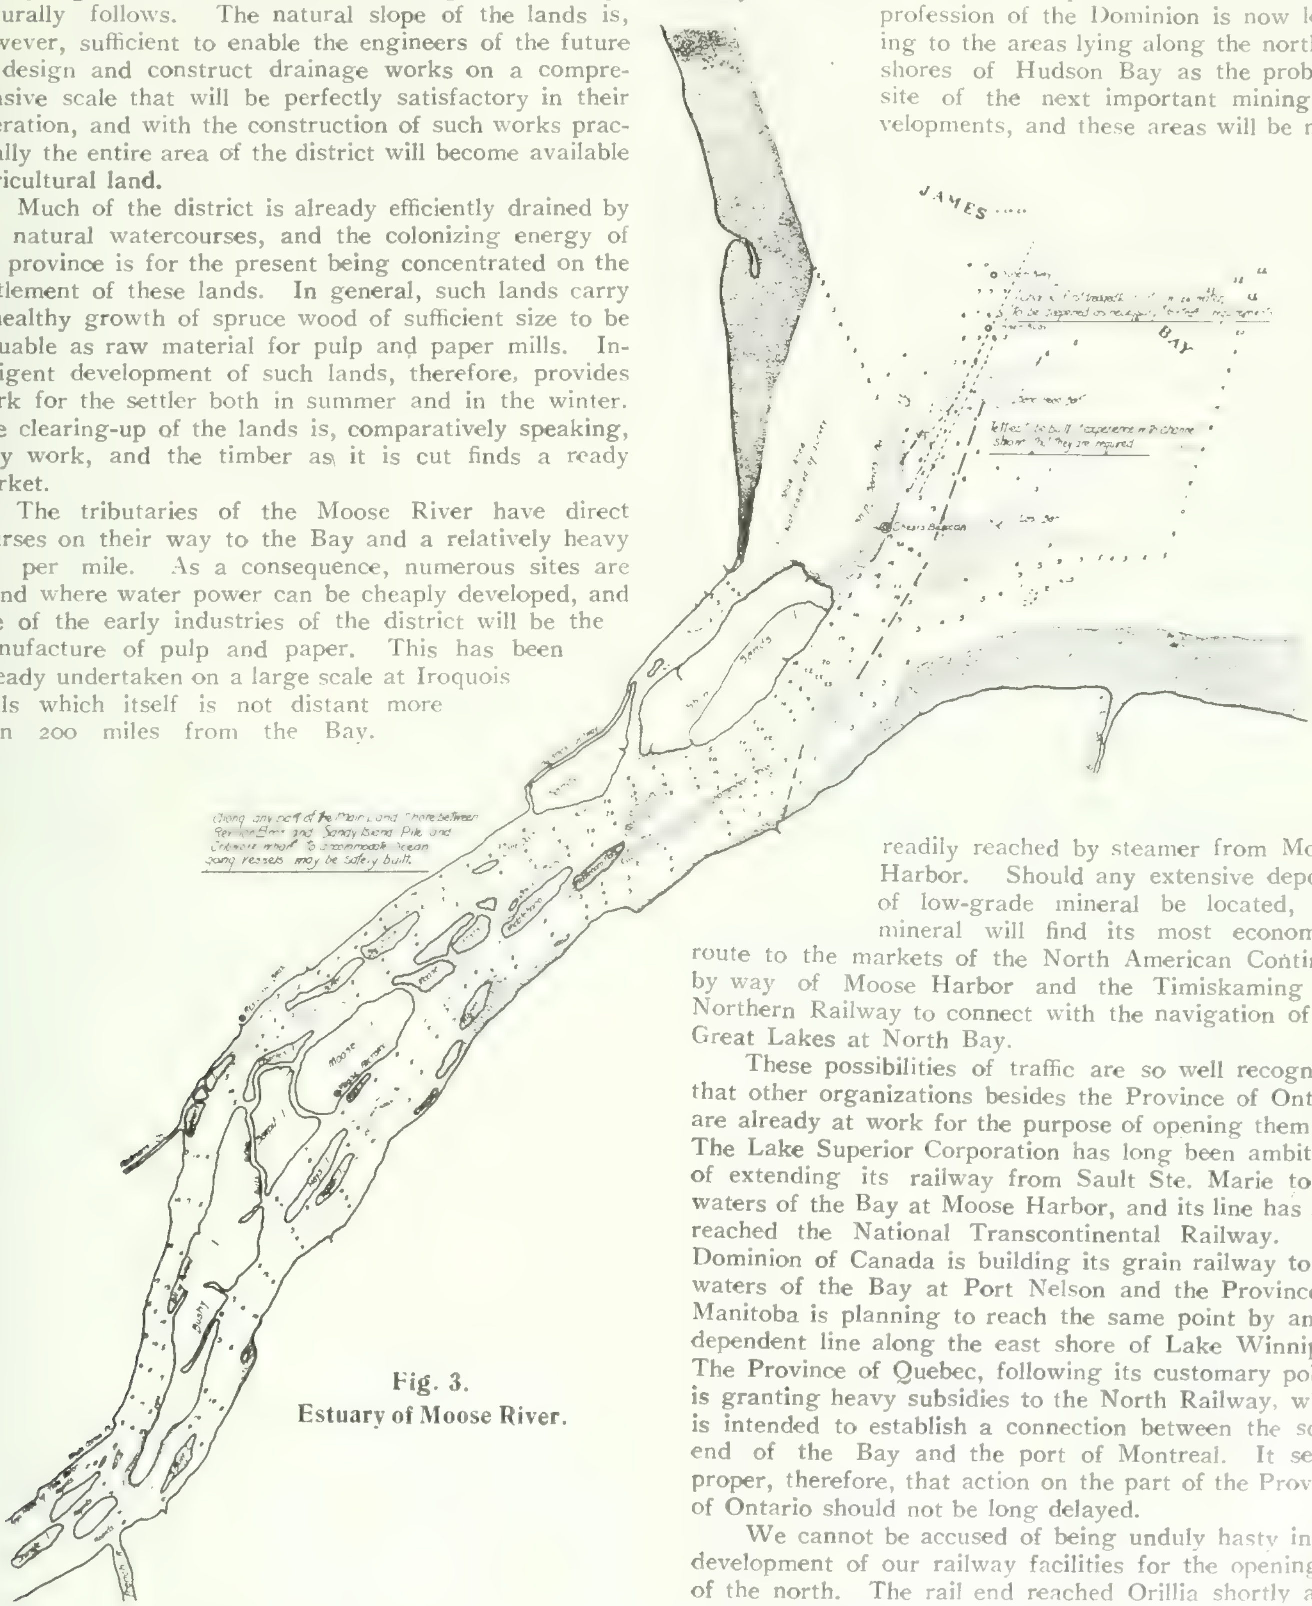

Fig. 3.
Estuary of Moose River.

In this development the opening of a port on the Bay must play a considerable part, providing a route by which such necessary materials as coal can be brought in without excessive freight charges and such low-grade materials as groundwood pulp can be exported, freight charges being perhaps the most important item in the market cost of the last-named product.

The district north of the height of land is so completely overlaid with clay that there is there little probability of further mineral development, but the mining profession of the Dominion is now looking to the areas lying along the northern shores of Hudson Bay as the probable site of the next important mining developments, and these areas will be most readily reached by steamer from Moose Harbor. Should any extensive deposits of low-grade mineral be located, this mineral will find its most economical route to the markets of the North American Continent by way of Moose Harbor and the Timiskaming and Northern Railway to connect with the navigation of the Great Lakes at North Bay.

These possibilities of traffic are so well recognized that other organizations besides the Province of Ontario are already at work for the purpose of opening them up. The Lake Superior Corporation has long been ambitious of extending its railway from Sault Ste. Marie to the waters of the Bay at Moose Harbor, and its line has now reached the National Transcontinental Railway. The Dominion of Canada is building its grain railway to the waters of the Bay at Port Nelson and the Province of Manitoba is planning to reach the same point by an independent line along the east shore of Lake Winnipeg. The Province of Quebec, following its customary policy, is granting heavy subsidies to the North Railway, which is intended to establish a connection between the south end of the Bay and the port of Montreal. It seems proper, therefore, that action on the part of the Province of Ontario should not be long delayed.

We cannot be accused of being unduly hasty in the development of our railway facilities for the opening-up of the north. The rail end reached Orillia shortly after 1870, it reached North Bay about 1886, and was continued from North Bay to Liskeard between 1900 and 1905, and on to Cochrane about 1910, an average movement northward of perhaps 10 miles per year.

Historically, Moose Harbor, under the name of Moose Factory, is an old and long-settled port, from

which the business of the surrounding country has been handled for nearly 250 years. Generations of people have lived and died there, and the suitability of the site as a point of permanent residence is beyond question. It is interesting to note that one of the earliest experiences of this settlement was its complete destruction in a time of peace by a marauding, overland expedition sent out from Montreal—apparently with the definite intention of maintaining the supremacy of that city as the centre of the fur trade. In fact, the commercial possibilities of the Bay received more attention between the years 1670 and 1700 than they have at any other time up to the present.

Moose Harbor provides a magnificent site for the creation of a great port. The estuary, shown in Fig. 3, is perhaps 20 miles long and varies from 1½ to 3 miles wide. It is crowded with islands, and through the intervening channels there discharges the great river which is never, so far as we know, smaller than the Ottawa River has been since the government has regulated the flow of that stream by its storage works. The settlements and fields on the islands give evidence of long occupation, and the flat-lying shores provide an ideal site for a rail and water terminal.

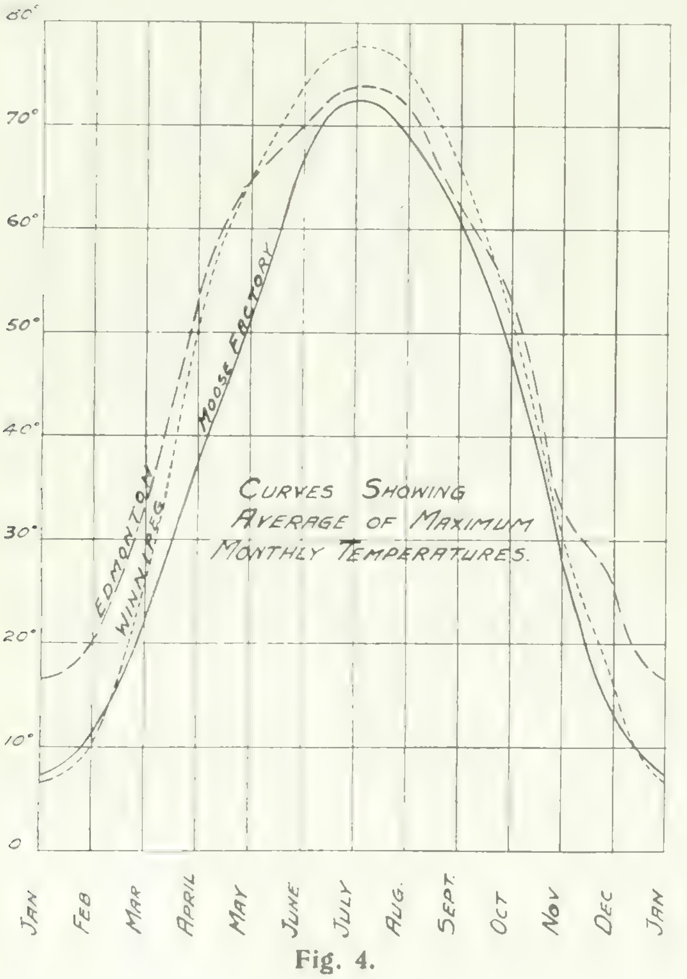

Fig. 4.

Up to the time that the commission issued its orders that the possibilities of this site were to be investigated there was a general impression that the construction of an ocean terminal at the south end of the Bay was for all practical purposes an impossibility, and that the shallow and rocky shores presented an obstacle that could not be overcome within the limits of reasonable cost. The first definite information concerning the locality was obtained by survey parties sent out in 1911, which made a complete instrumental survey of the estuary during that season. The natural conditions, as shown by the plans prepared from these surveys, were so advantageous that further instructions were given by the commission to continue the investigations and to ascertain fully facts concerning all natural conditions, both favorable and unfavorable.

Temperatures had long been under observation at the posts of the fur-trading companies and a study of the results of these observations showed that the Harbor had a winter temperature closely corresponding to that of Winnipeg. In summer and fall its temperature corresponds to that of Edmonton, but the spring is backward and most nearly corresponds to that of Cape Breton. The corresponding maximum, mean and minimum temperatures of Edmonton, Winnipeg and Moose Factory respectively are illustrated in Figs. 4, 5 and 6. Any Canadian, therefore, who knows his own country will encounter no new conditions of temperature if he is called upon to take up his residence in Moose Harbor.

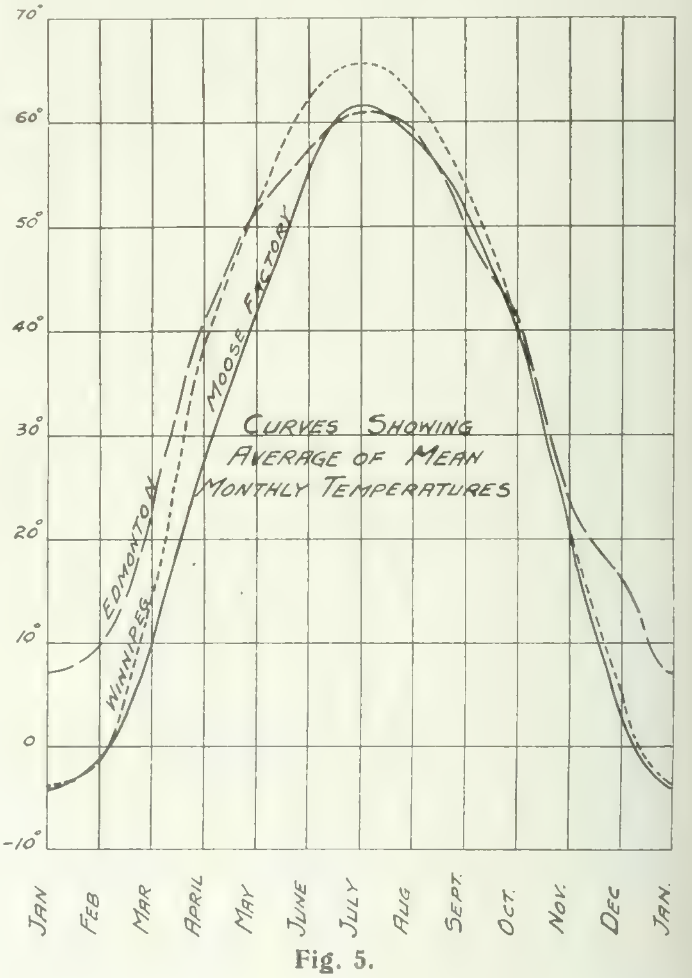

Fig. 5.

Observations have been made upon the tides in the estuary, and these are found to be of very moderate dimension, the range rarely exceeding 6 ft. and often being as low as 2 ft. In this respect, Moose Harbor compares very favorably with its rivals, Port Nelson and Rupert House, the extreme range of the one being given as 18 ft., and of the other as 12 ft.

Measurements have been made of the currents in the estuary created by the tides, and the maximum velocity of these currents, under ordinary conditions, has been found to be about 4½ lin. ft. per second, or, roughly, 2½ knots per hour. Such velocities will not in any way

interfere with the movement of modern steamship traffic. Higher velocities than those which have been determined by the observations will exist during the periods of the discharge of the spring floods, but as a general rule these floods will have passed by before the active traffic of the port commences for the year. Fig. 7 is a chart of tide velocities from the report of J. G. McMillan on the Moose River.

The surveys of 1911 showed that in the neighborhood of the fur-trading posts the river was divided into two great channels, and that the depth of water in these channels varied to such an extent that their improvement would be expensive.

Below the posts the two channels united into one broad and deep waterway, bordered by very extensive sand bars. The depth of water in the main channel varies at low tide from 15 to 20 ft., but this fairway is cut off from the main Bay by a bar having a total width of, roughly, 4 miles and a minimum depth of water at low tide of about 6 ft. Beyond the bar the depth of water steadily increases until at a short distance out soundings are secured that are satisfactory for any probable navigation.

The studies of the site have not yet been completed up to such a point that the engineers can give a very positive opinion concerning the method of formation of this bar. The bar itself constitutes the most formidable existing obstacle to the development of the port, and the method to be adopted for its removal will depend largely upon the cause of its formation. Similar bars have been formed in other rivers, sometimes out of the silt carried down by the river itself, and sometimes from silt carried by the littoral currents. It is questionable whether either of these methods of formation has been active at the mouth of the Moose River.

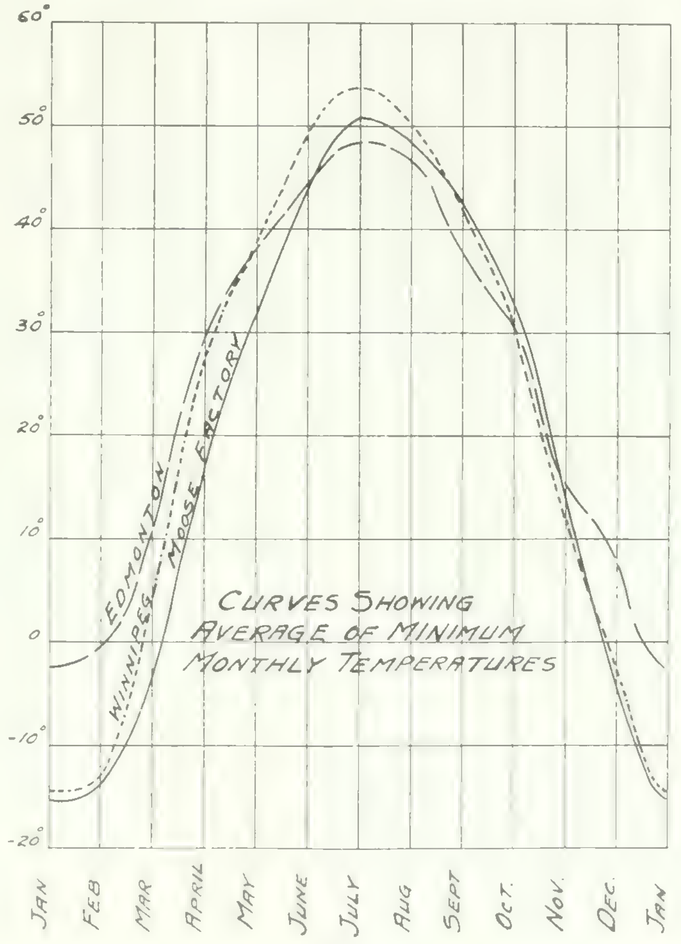

Fig. 6.

No effort has as yet been made to determine the direction and force of the littoral currents, but owing to the shallowness of the coast waters and to the exposed situation of the coastline strong and variable currents of this nature are certain to be found from time to time. Owing to the nature of the material along the shores, it is not believed that these currents will carry any large amount of silt with them, or that they have contributed materially to the existence of the river bar.

Efforts have been made to determine the quantity of silt carried down by the river itself; but although the waters at their ordinary stage are often discolored the material in suspension is so light that it is almost impossible to secure a deposit from a sample taken out of the river and it is probable that for at least nine months in the year the river carries with it no material that would be a factor in bar building. At the time of the annual break-up the shores and bed of the river are badly eroded by the ice-shoves and large quantities of earth and similar material are carried down into the estuary. During the early summer such deposits of material are distributed by the action of the tides and currents. In view of the fact that the spring discharge of the Moose River is very heavy and that the maximum currents will be found in the deepest channels, it is believed that there will be no appreciable deposit of silt in any channel which may be cut across the bar. There is evidence that the flood discharge of the river is as high as 400,000 second-feet, but this figure is not considered to be well established.

The theory held at present by the engineers is that the river channels have been cut through the clay bed of the Coastal Plain in an almost haphazard fashion by the waters of the river itself, and that the bar at the mouth simply consists of the material of the original bed of the Bay, no channel having been cut at this point because the velocity of the river water has been checked by its impact against the waters of the Bay. This theory can be partly confirmed by borings to determine the quality of the material in the bar, and the making of such borings was planned for the spring of 1913. In that year the ice went out of the river at an unexpectedly early date and the survey parties had to flee for their lives and were forced to abandon their equipments to the mercies of the ice-shoves. It is purposed to make good this deficiency in data during the present summer.

A number of borings have been made along the estuary and in each case the material found has been a material which can be readily and cheaply removed by dredging. Solid rock has been noted along the coast line some miles to the east and some miles to the west of the estuary, but not in its immediate vicinity. The borings also give some indication of solid rock in the bed of the river some miles above the fur-trading posts, but no such indications have been found in that portion of the river which it is proposed to improve.

Some time has been devoted to the study of such typical cases of bar formation as Toronto Island and as the Passes of the Mississippi River, but the underlying causes in these cases are forces which apparently are not at work to an appreciable extent in the estuary of the Moose River. The engineering precedents which have been established in dealing with natural difficulties similar to those just referred to will, none the less, be of great

value in determining the final lay-out for the development of Moose Harbor. Perhaps the most valuable of them is the now recognized persistence of a river in maintaining its banks and channels unaltered, even when these are built up of most easily eroded materials.

The depth that will be required in the channel at low water will naturally increase as the traffic increases. It is not believed that traffic conditions will justify the construction of a channel of more than 15 ft. depth at low water at first, and the excavation of a 300-ft. channel of this depth out to the Bay should cost in the neighborhood of $600,000. Heretofore all work of this nature in Canada has been carried out by the Department of Public Works and the estimate given above is based on the average cost of the dredging that has been done by that department. If precedent is followed, the cost of executing this portion of the development will fall upon the Dominion of Canada and not upon the Province of Ontario or the Timiskaming and Northern Ontario Railway.

At the post of the Hudson Bay Company an extended, but not wholly systematic, series of observations has been kept of the dates upon which the river has been closed by ice and of the dates of the annual spring break-up. Comparison between this record and a similar record for the port of Montreal has been made and shows, in Fig. 8, that the open season for the port of Montreal is more than a month longer than the similar season at Moose Harbor. The open season at Moose Harbor will have a duration of from 5½ to 6 months, and, should the traffic warrant the expense, it could be readily extended at both ends by the use of ice-breakers. In one respect the comparison above referred to is not fair to Moose Harbor in that it overlooks the fact that Moose Harbor is directly on tide water and is open to the sea as soon as the ice goes out. This is not true in the case of Montreal, where the river between Quebec and Montreal is not infrequently blocked by ice after the harbor of Montreal is itself clear. In the case of Moose Harbor, the action of the river waters in sweeping clear the harbor and the bay immediately in front of the estuary was one of the principal reasons for selecting a river terminal in place of a harbor constructed out into the bay itself.

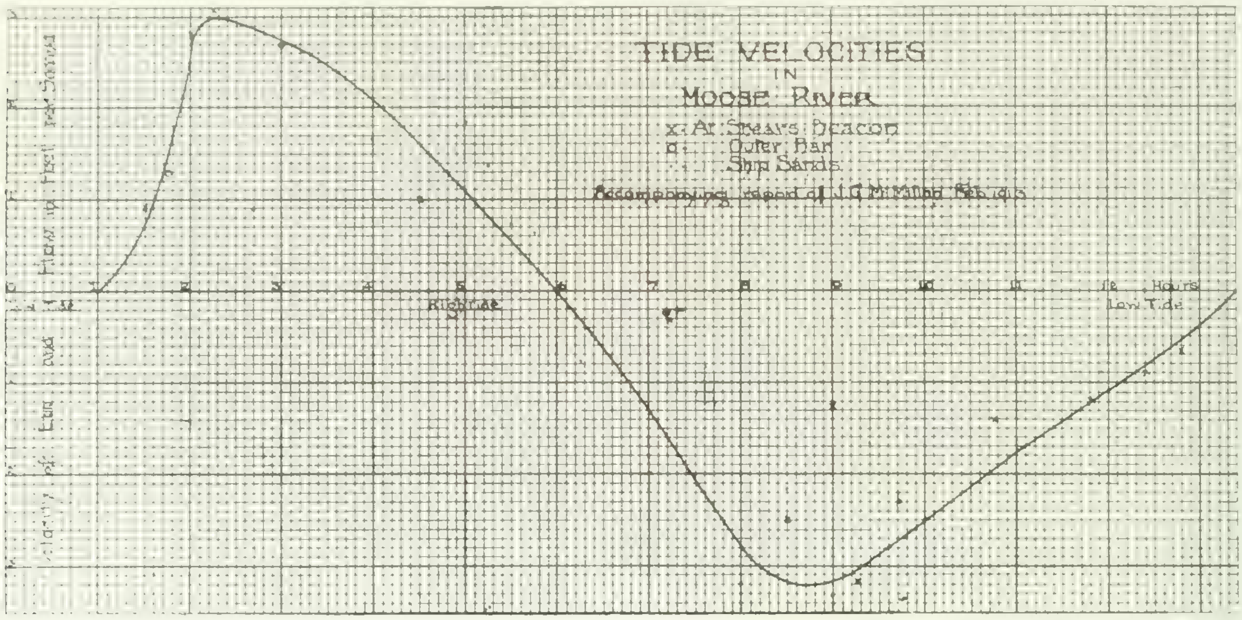

Fig. 7.

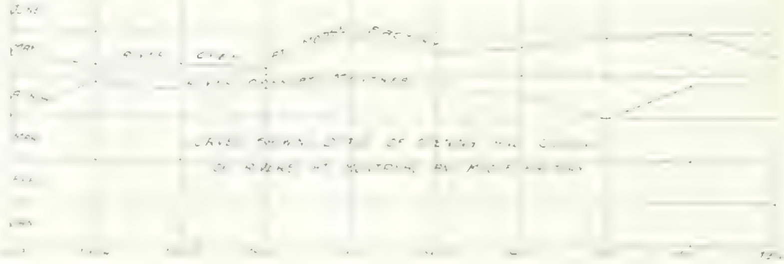

Fig. 8.

An examination of the winter ice cap over the estuary has shown that this cap consists of a fairly uniform sheet of about 3 ft. in thickness and that there is little drift ice or bordage under the main ice cap. Examination has also been made to determine whether frazil ice existed in quantity in the channels of the estuary, as it is usually found to exist in the lakes and pools of the St. Lawrence watershed. It was expected that, owing to the winter cold and to the rapid and turbulent course of Moose River, large quantities of this frazil ice would be found to be present as it was well-known from the labors of the Montreal Flood Commission of 1888 that such ice constituted one of the principal causes of the great spring floods in the harbor of Montreal. No explanation has as yet been advanced for the absence of

frazil ice from the Moose estuary, but this absence certainly removes from the undertaking one of the most serious difficulties that has to be overcome by Canadian hydraulic engineers.

Enquiry at the Hudson Bay post revealed the fact that only on rare occasions does the ice move quietly out of the harbor. As a general thing, the ice cap remains solid and undisturbed until it is shattered to pieces by a rush of water and float ice from the upper and more southerly portions of the river, and heavy shoves almost invariably accompany the clearing of the harbor. So far as spring conditions are concerned there is, indeed, a very close resemblance between Moose Harbor and Montreal. In each case there is a river of great width with many shallow areas, with obstructions in the form of islands, and with low-lying shores. The channels are blocked with ice and the clearing forces are the spring waters which, in the two cases, are not far from equal in quantity. The St. Lawrence River is a much greater stream than the Moose, but its flow throughout the year is also much better regulated, and as a consequence there is not on the St. Lawrence the great difference between the spring and fall discharge that exists in the case of the Moose River. The movements of the ice in the Moose estuary, as described by the officials of the Hudson Bay Company and by the observers sent out by the commission, are very similar to the well-known movements of the ice in Montreal harbor, and the construction methods that have long been followed with success in Montreal harbor may, with safety, be adopted by the engineers of the commission.

For possibly 100 years, wharf construction in Montreal took the form of heavy timber cribs built roughly parallel to the original shore of the river and to a height of 10 or 12 ft. above normal summer water. All sheds and handling apparatus were removed from the wharves every autumn, and invariably in the spring the flood waters rose until they were deep over the wharf sites. As the moving ice was lifted by the waters the force of the shoves was rarely found to have expanded itself upon the wharves themselves, although occasionally portions of the upper part of the wharves were completely torn away. The extent of such damage has been proved to be slight and it was always readily repaired from year to year. There is no evidence to show that the ice-shoves in Moose Harbor are as great or greater than some of the shoves that have been observed in recent years at Montreal, and it is believed that in the earlier years of its development no better plans can be made for Moose Harbor than those which have worked successfully for so long in Montreal.

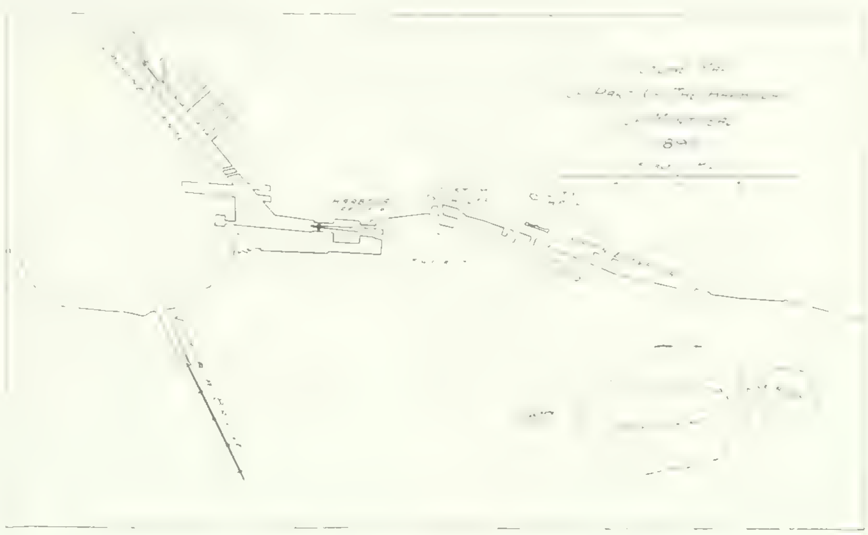

Fig. 9.

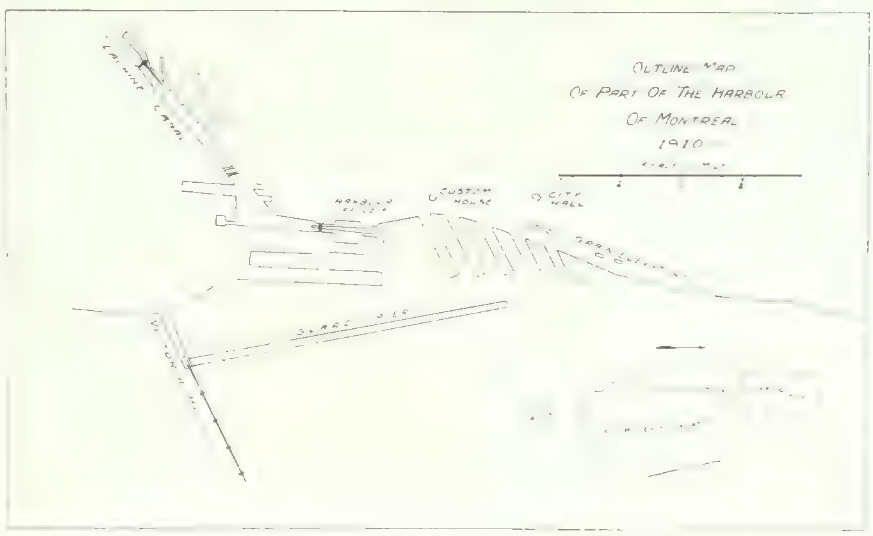

Fig. 10.

There is an excellent site on the north shore of the estuary, extending from the post of Révillon Frères to the head of Sandy Island, for a development on the Montreal principle. The channel in front of this shore is of satisfactory depth, and the lands behind it have the proper contour for an efficient railway yard. The cost of 1,000 ft. of crib wharfing may be estimated at approximately $150,000.

How often this wharf will be overflown in spring it is impossible to say, as the rise of the waters in the estuary, which reaches a maximum of 20 ft., is caused entirely by the ice-shoves and the location of these shoves is very variable from year to year. Sometimes the force of the break-up is expended as far as 15 miles above the bar, while at other times the shoving, jamming and flooding may continue to within three or four miles of the bar itself. In the spring of 1913 the final ice-shoves occurred at a point unprecedentedly low in the estuary, and the waters overflowed areas on which the engineers had, in a preliminary way, projected terminal works which were believed to be safe from flood.

Considering again the history of the port of Montreal, Fig. 9 shows a map of the port some 20 years ago, before it was decided that the traffic had grown to be of such importance that it could not be satisfactorily handled with terminal facilities that had to be removed out of the way of the action of the ice every year, and the present main harbor of Montreal was then designed, two principal

problems to be solved being protection from flooding and protection from the destructive force of the great ice-shoves which had been known to pile ice to the depth of 60 ft. upon the then existing wharves. The latter difficulty has been met by constructing across the face of the harbor and parallel to the main thread of the river an enormous earth bank known as the Guard Pier. The material for this pier was obtained from the bed of the river in enlarging and deepening the harbor, and it is built to such height that no ice-shove has passed over it and by reason of its material and shape it is practically invulnerable so far as damage from ice action is concerned. Behind the protection of this pier the present concrete and timber wharves of Montreal were built and to an elevation which protects them from flooding except under the most extreme conditions, and on these wharves have been built the permanent sheds and other equipment which now constitute the handling arrangements of the port of Montreal.

It is noteworthy that the engineer for the Montreal Harbor Commission, Mr. John Kennedy, M.Can.Soc. C.E., was so fully satisfied of the soundness of his plan of guard pier construction, shown in Fig. 10, that he did not hesitate to place the entire fleet of the commission in the river, but behind the guard pier, during the first winter following the completion of its construction, and the very slight movements of the ice which have since occurred behind the guard pier are satisfactory proof of the soundness of the principles followed in its design.

In Moose Harbor there is an excellent site at Sandy Island which can be readily converted into a protective harbor of the Montreal type whenever the traffic of the port has grown to such magnitude that it will justify the expenditure involved in such construction, and there appears to be no reason why this site should not be indefinitely reserved for the purpose.

It is not the view of the engineers of the commission that their work at Moose Harbor is yet so complete that the outlines of development, as now contemplated, will not be altered. It is proposed during the present year to determine the character of the material in the bar and to make a special study of the movements of the currents in the estuary. Attention will be given to the question of training walls in the neighborhood of the bar similar to those so successfully constructed by Captain Eads at the mouth of the Mississippi River, although, as already indicated, the judgment of the engineers is that the natural conditions in Moose Harbor do not call for the adoption of Mississippi methods.

As a conclusion, it may be said that the work which has been done up to date has proved beyond question that the construction of a deep-water terminal at Moose Harbor is perfectly feasible, and that it does not involve more than a very moderate expenditure. It may also be said that no problem will arise in the construction of the harbor works which has not already been successfully dealt with elsewhere, and that the exploratory surveys for the railway extension from the present terminus at Cochrane to the Harbor are so well advanced that this portion of the undertaking is known to be a piece of railway construction of the most ordinary type.

A [illegible]-mile concrete boulevard along the shore of Lake Michigan, from Chicago to Milwaukee, is being planned.

An announcement was made at the Maritime Motor Show in St. John, N.B., to the effect that the Dominion Motor Car Company will erect a factory at Coldbrook, N.B., [illegible] miles from St. John, to assemble and manufacture sections of [illegible] cars which will be placed on the Canadian market.

TAR FORMING TEMPERATURES OF AMERICAN COALS.

The University of Wisconsin has just issued a bulletin prepared by O. C. Berry, under the direction of Prof. A. G. Christie, on the characteristics of the volatile matter in bituminous coal. The bulletin covers a series of investigations to determine the temperature limits between which tars are distilled from various classes of coal; the temperature limits of the maximum rate of evolution of tars, and the relative quantities of tars distilled from various general classes of coal. The object of the research centres around the important part which volatile matter plays in determining how the coal must be handled in order to obtain the best results considering the enormous annual consumption of coal of various kinds. Tar, being one of the most important and troublesome constituents, especially where coal must be used in boiler furnaces or in producer plants, are the subject of a thorough examination along the above lines.

The bulletin gives a thorough discussion of coal and its characteristics and also of the problems related to the question of tar and combustion. This is followed by an explanation of the test conditions as compared with actual operating conditions and a record of the tests. The conclusions arrived at are as follows:

(1) Tars first commence to distil from any grade of bituminous or lignite coals at about 300 degrees C.

(2) The greatest quantity of tars are distilled between the temperatures of 375 degrees C. as an average lower limit and about 475 degrees C. as the final temperature.

(3) The tars have all been evolved on the average when the coal reaches a temperature of 550 degrees C., though in some cases tar did not cease to appear till the temperature reached 600 degrees C.

(4) The temperatures at which the tars distil are not dependent on either:

(*a*) the geological age of the coal,
(*b*) the amount of volatile matter in the coal,
(*c*) the ratio of carbon to hydrogen in the class of coal tested.

In other words, tars may be expected to appear or disappear at approximately the temperatures given above with any grade of American bituminous coal.

(5) There is no evident relation between the amount of tar evolved and the amount of volatile matter in coal.

(6) There is evidently a distinct relation between the amount of tar distilled and the geological formation of the coal, or, more particularly, the carbon-hydrogen ratio of the coal. The maximum amounts of thick tars can be expected from coals with carbon-hydrogen ratios ranging from about 13.5 to 18. It is also possible, knowing the carbon-hydrogen ratio of any given coal, to predict with considerable accuracy the probable amount of tar that will be distilled as compared with some other known coal.

(7) There are added reasons for believing that the volatile matter of western coals contain fixed gases and watery vapors of low heating value if not entirely non-combustible. This is shown by the small amounts of tar deposited and by the low heating value when calculated on the "unit coal" basis.

The Northern Electric Company, of Montreal, has recently closed a contract whereby it will establish in Regina its general headquarters for the west.

BOUNDARY WATERS OF RAINY RIVER DISTRICT.

THE negotiations between Canada and the United States relative to the water level of Lake of the Woods, and which have been under way for some time, formed the subject of a progress report dated January 16th, 1914, to the various governments by the International Joint Commission, to whom the matter was referred.

The collection of information has involved an immense amount of difficult field work, including flood damage surveys on the shores of the lake, storage surveys of the lakes in the vicinity of the international boundary tributary to the Rainy River and reconnaissance surveys of the secondary storage basins lying wholly within the boundaries of either country. The work was carried on under the supervision of Mr. A. V. White, of Toronto, and Mr. A. F. Meyer, of St. Paul, consulting engineers of the commission, by field parties appointed by both countries.

The following questions were submitted to the commissioners by the Canadian and United States governments:—

(1) In order to secure the most advantageous use of the waters of the Lake of the Woods and of the waters flowing into and from that lake on each side of the boundary for domestic and sanitary purposes, for navigation and transportation purposes, and for fishing purposes, and for power and irrigation purposes, and also in order to secure the most advantageous use of the shores and harbors of the lake and of the waters flowing into and from the lake, is it practicable and desirable to maintain the surface of the lake during the different seasons of the year at a certain stated level; and if so, at what level?

(2) If a certain stated level is recommended in answer to question No. 1, and if such level is higher than the normal or natural level of the lake, to what extent, if at all, would the lake, when maintained at such level, overflow the lowlands upon its southern border, or elsewhere on its border, and what is the value of the lands which would be submerged?

(3) In what way or manner, including the construction and operations of dams or other works at the outlets and inlets of the lake or in the waters which are directly or indirectly tributary to the lake or otherwise, is it possible and advisable to regulate the volume, use, and outflow of the waters of the lake so as to maintain the level recommended in answer to question No. 1, and by what means or arrangement can the proper construction and operation of regulating works, or a system or method of regulation, be best secured and maintained in order to insure the adequate protection and development of all the interests involved on both sides of the boundary, with the least possible damage to all rights and interests, both public and private, which may be effected by maintaining the proposed level?

During the winter months of 1912-13 the consulting engineers devoted their attention to the gathering of data from various governmental and other sources on both sides of the boundary. They also made a personal reconnaissance of portions of the Lake of the Woods watershed in order to ascertain the extent and character of the field work necessary to determine the best means by which regulation might be secured and also to determine the possible effect that certain schemes of regulation might have upon the various interests using the waters of the Lake of the Woods and the shores and harbors thereof.

During the winter the engineers also completed their plans for work in the field, and in the spring as soon as conditions would permit survey parties were gathering the essential data. This field work was prosecuted throughout the summer and autumn of 1913. The care with which the work was distributed and the energy with which it has been pushed forward has resulted in very substantial and gratifying progress in the gathering of important information upon some of which the commission will no doubt base its final report to the two governments.

While the investigation is still incomplete and all figures must be subject to revision, it is stated in the progress report that the watershed involved in the investigation—that is, the combined area of land and water surface above the outlet of the Lake of the Woods—is approximately 26,000 square miles, of which about 15,000 square miles are in Canada and 11,000 square miles in the United States. This area forms part of the Hudson Bay watershed, which finds its principal outlet through the Nelson River. Into the character and extent of the main watershed below the mouth of the Winnipeg River, it is unnecessary to inquire, so far as the present investigation is concerned, but it is important to have some general knowledge of the waters which join the Winnipeg River from the northwest, and which go to swell the volume contributed to that river by the Lake of the Woods and its tributaries. It is estimated that the English River and other affluents of the Winnipeg River below the outlet of the Lake of the Woods drain an area of about 29,000 square miles.

The intricate system of waterways which finds its outlet in the Lake of the Woods through Rainy River extends on the one side into northern Minnesota and on the other into western Ontario. This area above the mouth of Rainy River is approximately 20,000 square miles. That portion of it above the outlet of Rainy Lake is about 14,500 square miles. The Lake of the Woods itself contains an area of 1,400 square miles; Rainy Lake, 325 square miles; and there are also within the watershed some 36 lakes ranging in area from 10 to a hundred square miles, besides a large number of smaller bodies of water.

One of the results of the hearings was to bring out not only the variety and magnitude of the resources of the Lake of the Woods region, but also the importance of the interests involved in the development of these resources on both sides of the boundary. Not less than $100,000,000 have already been invested in this important district, including the lumber industry, pulp and paper mills, power plants, flour mills, fisheries, etc. The lumber mills are situated at various points on the Rainy River and the north shore of the Lake of the Woods, the valuable timber limits which supply them covering thousands of square miles in Ontario and Minnesota. Large pulp and paper mills are situated at International Falls, Minn., and Fort Frances, Ontario, and flour mills at Kenora, Ontario, on the north shore of the Lake of the Woods. Large power plants, representing an investment of many millions of dollars, are found at International Falls in connection with the pulp and paper industry, at Kenora for the operation of flour and other mills, and on Winnipeg River for the purpose of supplying light, heat, and power to the city of Winnipeg and operating the Winnipeg street railway. The towns of International Falls, Fort Frances, and Kenora are also lighted by the power plants in their vicinity.

Navigation has been maintained more or less on the Lake of the Woods and Rainy River for over 30 years by steam craft engaged in freight and passenger service, lumbering, and the fisheries. The navigation interests complained that their operations were interfered with by low water in Rainy River, caused by the operation of the power works at International Falls and Fort Frances.

The Canadian government has shown its interests in the navigation of these waters by subsidizing a line of steamers between Fort Frances and Kenora, by extensive dredging at the mouth of Rainy River, and by the provision of lights and other aids to navigation. The United States government has also carried out dredging at Warroad and elsewhere on the south shore of Lake of the Woods. Some years ago a sum of money was voted by the Canadian Parliament for improving the navigation of Rainy River at the Long Sault Rapids by means of a dam and lock. Difficulties arose owing to the international character of the stream, and in 1911 a private corporation, the Western Canal Company, was incorporated having the same object in view. Nothing, however, has yet been accomplished.

Many years ago the Canadian government built a canal on the Canadian side of the river at International Falls. This canal is now closed at the upper end by the waste gates of the power dam, but the Canadian government has reserved the right to re-open the canal whenever it may be required for navigation purposes. In the plans of the power company the United States government also ordered provision for a canal on the American side, should it be found necessary at any future time. In connection with these existing or projected locks at International Falls and the Long Sault Rapids, mention may be made of a larger project, which has been mooted in Canada, for creating a navigable waterway by means of a series of locks and dams and the improvement of existing waterways between Lake Superior and Lake Winnipeg.

A large portion of the country surrounding the Lake of the Woods and its tributaries is not of a nature suitable to agriculture, but farming is being carried on along the banks of Rainy River; on the south shore of the Lake of the Woods, where there is much valuable agricultural land, in the neighborhood of the North West Angle, on the eastern shore of the lake north of Rainy River, and on some of the islands. Complaints have been made that some of these lands, which are low lying, have been flooded by reason of the maintenance of the Lake of the Woods above its natural level by the operation of dams at the outlet of the lake, which dams are wholly in Canadian territory.

The fisheries of the Lake of the Woods are both extensive and valuable. Over 1,500,000 pounds of fish were shipped from these waters in 1912. Statements were made at the hearings to the effect that changes of level in the lake were detrimental to the fisheries, as the lowering of the water injures the spawning grounds.

Some evidence was obtained at the hearings at International Falls, Warroad, and Kenora as to sanitation and the pollution of waterways. Complaints have since been received as to the pollution of the waters of Rainy River by sewage disposal and by the dumping of refuse from the pulp and paper mills at International Falls.

The hearings held by the commission in September, 1912, indicated in a general way the requirements of the various interests concerned in the levels of Lake of the Woods:

(1) Navigation, requiring a high summer level of the lake.

(2) Agriculture, immediately along the shore of the Lake of the Woods, requiring a fixed maximum level, which will obviate undue flooding and make available the greatest area along the shore for agricultural purposes.

(3) Industries, broadly divided into: (*a*) Manufacturing interests, requiring a more or less uniform flow throughout the year. (*b*) Municipal plants for light, heat and power, requiring a regulated flow, which varies with the seasons, the winter loads being heavier and necessitating an increased flow.

(4) Fishing, requiring a fairly uniform lake level, otherwise considerable fluctuations will expose reefs and destroy fish spawn.

Difficulties in Regulating Lake Levels.—The harmonizing of these interests, which under the extremes of demand are conflicting, makes the problem of the regulation of lake levels somewhat difficult. The regulation of the levels of the Lake of the Woods, having in view not only present but prospective needs, depends upon the regulation of the inflow as well as that of the outflow. It therefore involves two classes of controlling works:

(*a*) Primary works, to be located in boundary waters at the outlets from the Lake of the Woods.

(*b*) Secondary works, to be located in each country, to regulate the run-off into the boundary waters which supply that lake.

In view of the entire drainage area involved, about 26,000 square miles, being largely wooded, these secondary controlling works, necessary in a measure to-day, will become imperative in the future. And the vast interests depending on the timber supply in this great watershed must be concerned in the upkeep of that supply, so closely related to the conservation of the water resources of the district.

The field work in connection with the investigation has been divided into several more or less distinct sections:

(1) Detail and reconnaissance surveys of the shores of the Lake of the Woods, Rainy Lake, Namakan, Kabetogama, Sand Point, Crane, and a number of other lakes.

(2) Topographic and other data relating to outlets of Lake of the Woods.

(3) Stream flow records and meteorological data throughout the drainage area.

Extent and Necessity of Surveys.—The surveys in connection with the Lake of the Woods fall naturally into two classes. So far as the south shore of the lake is concerned, and certain areas on the east and west shores, where the lands are low lying, detail surveys are being made to show the effect on these lands—particularly those susceptible of cultivation—of various levels of the lake. The north shore, on the other hand, is generally more elevated, and a comparatively rapid reconnaissance survey was considered sufficient to obtain the data needed in connection with the investigation.

Between the months of June and October, 1913, a party of engineers made a detailed topographic and hydrographic survey of the lowlands along the southern border of the Lake of the Woods, from a point in Manitoba two miles north of the international boundary, south and east through Minnesota, and north again into Ontario, to a point about three miles northeast of the mouth of Rainy River. This survey covered about 70 square miles of actual area, and has been carried out in a manner to enable the commissioners to answer to what extent, if at all, would the lake, when maintained at such level, overflow the lowlands upon its southern border.

The field work elsewhere on the Lake of the Woods, comparable in character to that already done on the south shore, will cover certain areas on the easterly shore of the lake from near the mouth of Rainy River up to and including portions of the Big Grassy River, also on the west shore from about the international boundary northward to North West Angle Inlet. It is proposed to place the engineers in the field as early as practicable this spring and conclude the surveys before the early fall of 1914.

In carrying out the reconnaissance survey of the northern portion of the Lake of the Woods, including the principal islands and the shores of Shoal Lake, work was commenced in September, 1913, at Kenora and carried along the north and east shores of the lake to the mouth of Miles Bay. The entire shore line of the Lake of the Woods, including the principal islands and Shoal Lake, has now been examined, with the exception of the comparatively small areas on the east and west shores already referred to.

As Rainy Lake is the most important secondary storage reservoir in the Lake of the Woods watershed, and the level of the lake is controlled by the dam at International Falls, it was considered necessary to ascertain to what extent it could be utilized for storage purposes, and what the effect of certain levels would be on the surrounding lands, timber, etc. This survey has been completed, and the results are now being plotted, collated, and analyzed in the office.

It being thought desirable to have an examination made of some of the larger secondary storage reservoirs above Rainy Lake and lying wholly within the Province of Ontario, arrangements were made with the hydrographic branch of the Hydro-Electric Power Commission of Ontario to carry out the work.

These surveys were carried out in the summer of 1913, and included an examination of Upper and Lower Manitou Lakes, Otukemamoan Lake, White Otter Lake, Clearwater Lake, and Lac des Milles Lacs. As a result of this reconnaissance the following opinions have been advanced:

(1) That in all cases it would be physically possible to construct storage works of sufficient extent to entirely control the run-off of the watersheds above the outlets of the various lakes.

(2) That works of sufficient extent to control the run-off above the outlet of Lac des Milles Lacs would add considerably to the area of the lake due to the drawing out of large tracts of muskeg, and that some damage would be caused by backwater in the village of Savarne.

(3) In the case of all the other wakes examined the entire run-off of their respective watersheds could be controlled by comparatively inexpensive works without damaging timber of any value and without material increase in lake area.

(4) That dams have at one time or another existed at the outlets of all the above lakes, and timber dams in good condition now exist at the outlets of Manitou, White Otter, and Clearwater Lakes.

Arrangements have been made with the Public Works Department of Canada for certain surveys in the vicinity of the Long Sault Rapids, at the lower end of Rainy River, but as it was not found possible for the department engineers to complete this work during the season of 1913 a small survey party was detailed by the consulting engineers to make a preliminary survey.

During the summer of 1913 surveys above Kettle Falls were resumed and embraced the north shore of Namakan Lake.

During 1913 a number of men of the Manitoba hydrographic survey of the Canadian Department of the Interior have been engaged in collecting hydrographic data and in making surveys of the various outlets of the Lake of the Woods in the vicinity of Kenora and Keewatin.

In addition to the general field work, consisting of detail and reconnaissance surveys, water gauges, established by departments of both governments, and the commission were being read once, twice, or three times daily at various points on the Lake of the Woods watershed. Current meter gaugings were made almost daily at the various outlets of the Lake of the Woods, and frequent meter gaugings were also made of various tributary waters. Complete meteorological records, embracing temperature, humidity, rainfall, evaporation, and wind velocity were kept daily during the season.

Although only a little more than a year has elapsed since the investigation was begun, the commission in that time covered by surveys and reconnaisance a large portion of the drainage area of about 26,000 square miles, and has also collected a vast amount of necessary and important engineering data and obtained much other necessary information concerning the interests of the people in both countries to be affected by the final conclusions and recommendations of the commission. The data and information thus far obtained is being tabulated and put in proper and convenient form and from which maps are being prepared for the use of the commission in forming and illustrating its conclusions on which final recommendations to the United States and Canada can be based.

The waters involved in this investigation mark the boundary between two great countries for a distance of almost 500 miles. These waters are the common property of the United States and Canada. The right to their use is a right enjoyed in common by millions or more people living under separate and distinct governmental jurisdictions along and in the vicinity of the boundary thus marked. Heretofore the exercise by the people of both countries of this common right to the use of these waters without international agreement or other limitation has, as we are informed, led to frequent and sometimes serious and acrimonious controversies and diplomatic negotiations between the two governments. These controversies have extended over a period of more than 15 years. At times they became so serious as to threaten destruction of private property.

Conclusions and recommendations, therefore, as to the normal levels and other conditions surrounding the use of these waters, their future regulation and control and the limits within which the people on both sides of the boundary may hereafter exercise their common right to use these waters for sanitary and domestic purposes, for navigation, for fishing, for power, and for municipal and industrial purposes generally, to be of value to the governments must necessarily be based upon the most careful and thorough examination of all the facts essential to intelligent and correct conclusions and practical recommendations. While the work thus far has been conducted with all the expedition possible and at a minimum cost, to complete it will require at least as much time and labor as has thus far been expended.

At a representative meeting of the Niagara District Hydro Radial Union at St. Catharines, it was decided to ask the various municipalities in Lincoln, Welland, Haldimand and East Wentworth to petition the Hydro-Electric Commission at the [illegible] to make a survey for a proposed radial line through the peninsula.

MECHANICAL PURIFICATION OF SEWAGE

Description of Riensch-Wurl Screen as Used in German Practice.

THE Riensch-Wurl Separator Disc is now being used in a large number of German sewage screening plants. The following are interesting abstracts from an article by Engineer Endris, of Hamburg, Germany, which is being distributed by the Sanitation Corporation of New York City, who have obtained the Canadian patent rights to the Riensch-Worl and other German sewage apparatus:

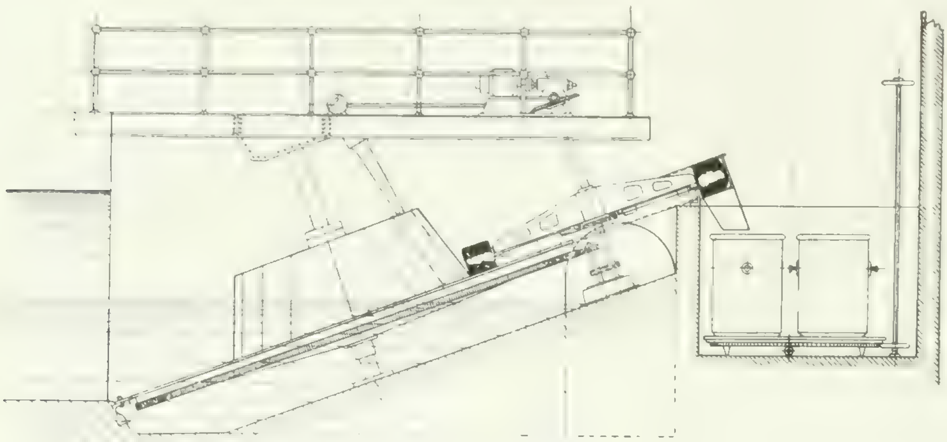

Fig. 1.—Elementary Outline of Riensch-Wurl Screen.

"The construction and method of the disc is clearly shown by the accompanying illustrations. It consists of a round disc provided with slots, the disc being suitably located at an inclined angle of 10 degrees to 30 degrees in the sewer, completely closing the cross-section of the canal. As Fig. 2 shows, the upper part of the disc extends above the water. The profile of the disc always conforms closely to the surfaces of the canals and has the advantage that the surface offered to the water entrance increases to the proportion of the rapidity of the increase in the canal profile, which is not the case in a rectangular pipe. The diameter of the disc is chosen to suit the volume of sewage and ranges between 1.3 to 8 m.

"The capacity of the disc depends upon the rapidity of flow, and the size of the slots, and is between 6 and 4,500 liters per second. The effluent of the main sewer is conducted diagonally against the disc. Shortly after the immersion of the rotating screen, it is covered with suspended matter, and during its travel through the water forms a sort of sludge filter, by which particles considerably smaller than the width of the slots are retained. On its exit from the water the screen is covered with solid substances of all kinds, as shown in Fig. 2. The solid substances are cleaned off above the surface of the water by a set of rotating brushes mounted on a spider, which revolve around the spider shaft and also on their own axis.

"In consequence of a special construction the bristles of the brushes are not pressed against the screen plate with too much force, nor the dirt squeezed through the slots, but the screen plate is gone over lightly and every spot brushed several times. The brushes carry the sludge into a circular trough, from which it is further transported by buckets, belt conveyer, tilting carts, or other device.

"In Fig. 1, the separator screen consists of two firmly connected parts, a smooth ring part, which lies diagonally in the sewage stream, and a hat-shaped frustum of a cone. The screen cone is cleaned by a special brush, the screen disc is in turn cleaned by revolving brushes.

"The usefulness of the screen depends particularly upon the construction of the screen plates which separate the solids from the fluids. They are made of bronze or brass, slots of cone shape, widened out on the under side about ½ to 5 m.m. wide. The screen plates are so arranged on the iron framework as to cause the least possible loss of head in the water.

"The screen surface, being made of large plates, insures a smooth and uniform surface without any projections on which sludge might possibly accumulate, while the close arrangement of the perforations provides the most advantageous possible use of the screen for the passage of the water.

"The framework (Fig. 1) is braced rigidly on all sides. All the load carried in a single one of the arms of the disc is cared for by a structural iron framework and is borne up by the main shaft itself. In the smaller and the medium sizes, up to 5 m.m. in diameter, the framework is secured to the carrying shaft and is hung to ball-bearing support which is supported by the service bridge. The ball-bearing support is constructed as pivot over the surface of the water. In the larger types (5 m.m. in diameter and over) the shaft is stationary and the framework of the screen rotates in a ball-bearing support arranged around the shaft above the water. In this way all the weight is taken up by the supports above the surface of the sewage and is easily cared for. A steady bearing is provided for the lower part of the main shaft, and consists of a roller bearing equipped with stuffing boxes.

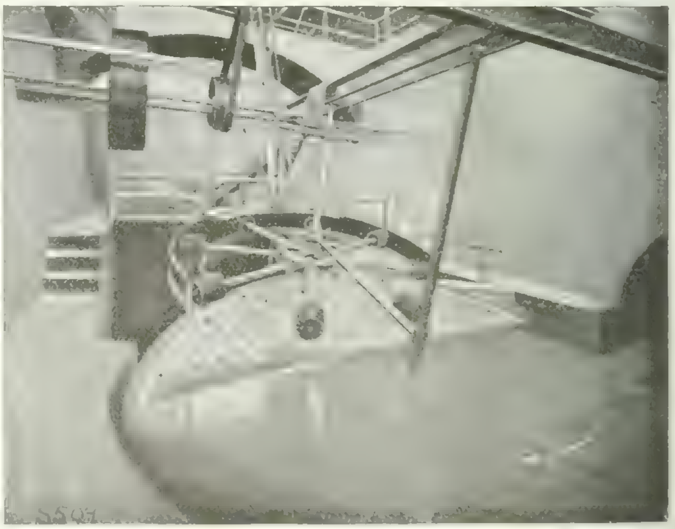

Fig. 2.—Riensch-Wurl Screen, Showing Method of Operation.

"Thorough lubrication, together with the slow rotatory movement (0.3-0.2 rotations per minute) and the small power consumed insures freedom from trouble.

"The manner in which the brushes are attached to a central brush body with radiating arms, makes the cleaning of the discs particularly efficacious. While in all other screen arrangements the screen surface is cleaned only once at each rotation the distribution of the brushes in the Riensch-Werl system permits the cleansing of the plates as frequently as desired. Normally, the screen plates are cleaned from 4 to 5 times each rotation in such a manner that a clean brush passes over the previously brushed surface. The brushes describe intersecting paths on the plates so that no single spot is left untouched by them.

"Summarizing the principle features of the screen:

"Large screening surface, high efficiency, low consumption of power and slight running expense, slight loss of head involved, adequate and substantial construction details, noiseless rotatory motion, and cleanliness. The mechanism is constantly in sight and the cleaning of it takes place above water; the clearance with walls of canal is precise and adjustable."

EFFECT OF CONCRETE ON STEEL.

That concrete has a preservative effect on steel has long been known, and many instances have occurred where ancient concrete has been broken away from metal with which it had been in contact for ages, and it has been found that the surface of the metal was as bright and clean as on the day when it was first placed in position. Some remarks made by Dr. W. H. Walker (the Director of the Research Laboratory of Applied Chemistry of the Massachusetts Institute of Technology) some little time ago will well bear repeating in this connection. Every engineer is well aware of the fact that acidulated water, no matter how small the percentage of acid may be, tends to corrode steel by increasing the number of hydrogen ions present, and Dr. Walker made it clear from the tests he carried out that there were certain alkaline substances present in concrete which corrected any acidity, and so protected the contained metal work from corrosion.

This fact has an important bearing upon the question, which lately has been much discussed, as to whether concrete will protect iron or steel from corrosion. Inasmuch as Portland cement, when it sets or hardens, liberates a quantity of caustic lime, which is a strong alkali, and since good concrete is saturated with this strong alkali, the answer to the question must be in the affirmative. Iron or steel will not corrode when embedded in concrete. But caustic lime is soluble in water, and poorly made concrete is not impervious to moisture. Therefore, if iron be embedded in concrete through which water is allowed at any time to percolate, this calcium hydrate will be slowly, but surely, dissolved. With it will disappear the inhibiting action of the concrete and iron embedded therein will, in time, rust and become corroded. To ensure absolute protection of the reinforcing members of concrete construction, therefore, such concrete must be of good quality, and sufficiently dense and carefully made to render it waterproof.

The Aztec Oil and Asphalt Refining Company of Canada have moved from the Shaughnessy Building, Montreal, to larger offices in the Power Building, Craig Street, Montreal.

ENGLISH FOR ENGINEERS.

By Benjamin P. Kurtz,
(In California Journal of Technology.)

When facts of iron and steel, of girders and trusses, are turned into a written report, they are presented no longer in their own tangible, objective medium or material, but in the new and subjective medium of words. Now, in the first place, it is to be noted that in this passage from the realm of objective reality to written representation there is ever present the dangerous chance of deflection of facts and even of their actual transformation—in a word, the danger of error. This merely because of the sudden transition to a new and unaccustomed medium. More narrowly regarded, however, the difficulty arising here is that of accuracy of statement plus the adaptation of technical facts and information to the laws and economy of mental attention. In order to gain and hold the attention of the reader, in order to present facts in such fashion that they may be easily and thoroughly understood, and that the general proposition may be seen to be supported at every point by its details, so that there is the mutual proof of a complete harmony between parts and the whole—in order to accomplish this successful communication with another mind, it at once becomes necessary to marshal the objective facts or material in such fashion that they will find a ready, orderly, and emphatic entrance into the mind of the reader. Facts without grouping dissipate the attention; poor grouping, overlapping, division, insufficiently marked separation confuse the attention; diffuse, wandering connections weary the attention; neglect to distinguish between division and implication, or between fact and hypothesis, muddle the conception of the reader; tortuous and nebulous sentences befog the conception of the writer; insufficient recognition of the necessity of exemplification and illustration, and ignorance of their difference, leave the reader too much to do or undo; the very lack of knowledge of what constitutes a definition, and of the fundamental methods of expanding a logical definition, lay the entire argument open to objection or render its outlines amorphous. In two words, the necessity of being understood, not the achievement of truth; the necessity of presenting groups of facts in accordance with the habits of trained thought-attention, not the accuracy of turning one fact into one phase—this is that new labor and skill required of the technician when he expounds his facts and thoughts to other minds in the medium of words.

BRIQUETTING OF SLACK.

"Conservation" calls attention to the fact that much coal is never utilized in Canada through piling the slack into huge "dumps." Such material is very valuable, and by means of a briquetting plant, may be converted into fuel of commercial value. Tests made in the United States show that the cost per ton of briquettes loaded on cars, from a briquetting plant at the mine would vary from about $3.50 to $5. The binder used is tar, which may be obtained as a by-product in the manufacture of coke. The briquettes withstand weathering better than ordinary coal, and there is less waste in shipment.

Renewed application will be made to the Railway Commission to order a start by the C.P.R. on its proposed freight tunnel from Burrard Street to the False Creek yards, according to a recent decision of the bridges and railways committee of the city council.

SOME LARGE CONCRETE BRIDGES

EXAMPLES OF THE APPLICATION OF CONCRETE TO BRIDGE DESIGN FOR VARIOUS USES—DETAILS OF THE IMPORTANT CONCRETE BRIDGES.

By L. S. BRUNER, A.M. Can. Soc. C.E.

CONCRETE, in its modern meaning, has been used in bridge construction for a great many years. While at first these structures were rather small, there has been a gradual increase in the length of the spans and length over all until at present we see arches of over 300 feet and viaducts of from half a mile to several miles in length.

Paulin's Kill Viaduct, D.L. & W.RR.—1,100 ft. long, 115 ft. above water.

The last few years have witnessed a remarkable growth in the use of concrete for long bridges and viaducts. They have been used for all classes of traffic, from those over which the traffic is entirely vehicular, to combined vehicular and trolley, and also railways.

One of the earlier of these immense structures was the Walnut Lane bridge in Philadelphia. It spans the Wissahickon Creek, the valley of which is a part of Fairmount Park, and connects Germantown and Roxborough, two of the city's finest residential districts. Prior to the construction of this bridge all traffic between the districts had to make a wide detour.

The total length of the bridge is 585 feet, consisting of a main span of 233 feet and five secondary spans. No reinforcement was used in the arch construction. The roadway is 150 feet above the creek and has a width of 56 feet, including sidewalks. The total cost was $262,000.

Concrete was decided upon principally for two reasons. In the first place the surroundings were such as to warrant a structure that would be in keeping with the natural beauty of the valley with its high wooded slopes on either side of the winding creek. Further, it was recognized that the maintenance of concrete would be very slight, due to the nature of the material and its great durability. While a fund for maintenance could have been provided for in any other class of structure, there was always the danger that the actual repair work might be neglected and the bridge become dangerous or unsightly, due to lack of proper care.

Following the construction of the Walnut Lane bridge, large concrete bridges and viaducts seemed to spring up all over the continent as well as in other parts of the world. Hardly was this bridge started before the Salt Lake, Los Angeles and San Pedro Railroad began the construction of a reinforced concrete bridge 1,000 feet long over the Santa Ana River at River Side, California.

Black Bay Bridge, Current River, Port Arthur, Ont.

The year 1910 saw the completion of Medina River bridge at San Antonio, Texas; the Almendares bridge at Havana, Cuba; and the Rocky River bridge at Cleveland, Ohio. The last named bridge was the largest of these, having a total length of about 800 feet and a main span

Allentown Viaduct—2,650 ft. long, 140 ft. high.

of 280 feet, 47 feet longer than that of Walnut Lane. This bridge is 100 feet high and contains 26,000 cubic yards of concrete. It was completed at a cost of $208,302.

All kinds and conditions of construction are represented in the later bridges. The Risorgimento bridge at

Munro Street Bridge, Spokane, Wash.

Rome, Italy, with a span of 328 feet, is built on a pile foundation, the soil being almost a liquid mud. The Dallas-Oak Cliff viaduct in Texas, the total length of which is 4,778 feet, has 51 arches, almost all of which are founded on piles. Spokane, Wash., subject to great extremes of temperature, boasts two of the larger structures. The first, Monroe Street bridge, has a main arch of 281-foot span and a length over all of 784 feet. The second bridge, completed last year, is 940 feet long.

Quite a few of these bridges are over a thousand feet in length. These are: West 7th Street bridge, Fort Worth, Texas, 1,041 feet; Dan River bridge, Danville, Virginia, 1,064 feet; Martin's Creek viaduct, Kingsley, Pa., 1,200 feet; Connecticut River bridge, Washington, D.C., 1,341 feet; Penn Street bridge, Reading, Pa., 1,350 feet; Delaware River bridge, Yardley, Pa., 1,446 feet; Colorado Street bridge, Pasadena, Cal., 1,470 feet; Catawba River bridge, Charlotte, N.C., 1,670 feet; Main Street viaduct, Fort Worth, Texas, 1,752 feet; King's Highway viaduct, St. Louis, Mo., 1,857 feet; Grand Avenue viaduct, Milwaukee, Wis., 2,088 feet; Tunkhannock Creek viaduct, Nicholson, Pa., 2,230 feet; South Eighth Street viaduct, Allentown, Pa., 2,600 feet; Dallas-Oak Cliff viaduct, Texas, 4,778 feet, and the Galveston, Texas, causeway, 12,642 feet.

More complete details of the most important bridges are given in the table on next page.

Walnut Lane Bridge, Philadelphia.

The Ford Motor Company are looking for an appropriate site for the construction of a large assembling plant at or close to Winnipeg.

The Metal Shingle and Siding Company, with headquarters at Preston, Ont., has decided to establish a branch at Regina, Sask.

For the first three months of the year the British coal and coke shipping trade exceeded 18,234,300 tons, as compared with 18,028,400 tons for the corresponding period of 1913.

It is reported from Sarnia, Ont., that a prominent manufacturing firm in the United States is looking for a good location at Point Edward, on which it intends to build a good-sized plant for the manufacture of a creosote preparation for use on block pavements and railway ties.

Definite word has been given to the Mayor of Medicine Hat, Alta., to the effect that the Maple Leaf Milling Co. of Toronto will commence construction on its plant at Medicine Hat in May; and also the Ontario and Manitoba Milling Company will commence construction on a plant very shortly. The two companies represent an investment of about $2,000,000. This word follows upon the recent statement that the Saskatchewan Bridge and Iron Works will commence its $1,000,000 plant at Medicine Hat within 30 days.

The Asphalt and Supply Company Limited, of Montreal, have moved from the Transportation Building to larger offices in the Board of Trade Building, Suite 303 to 307.

Announcement is made of the 14th annual 6 weeks' summer school of the College of Engineering of the University of Wisconsin, which opens on June 22nd. Courses of instruction and laboratory practice are offered in electrical, hydraulic, steam and gas engineering, mechanical drawing, applied mechanics, testing of materials, machine design, shopwork and surveying, in addition to which, subjects may be taken in the College of Letters and Science.

Gifford-Wood Company, of Hudson, N.Y., are celebrating the 100th anniversary of the founding of their business. In 1814 Elihu Gifford, grandfather of the present general manager of the company, founded the business at Hudson. In 1905 the business founded by the Gifford family was amalgamated with the firm of William T. Wood and Company, of Arlington, Mass. The Wood firm also dates back to the very early part of the 19th century. In commemoration of the 100th [illegible] the firm [illegible] a handsome souvenir booklet, giving photographs of the works; of the executive staff; and of the ice-handling machinery, ice tools, coal-handling machinery, elevators and conveyers, and other equipment which they manufacture.

CONTENTS OF THIS ISSUE.

ARCHITECTURE IN ENGINEERING WORK.

During the last few years considerable attention has been paid to the aesthetic appearance of the engineer's work, especially in the larger undertakings. Much, however, might be accomplished to render the engineer's solution of the smaller problems not only economical and useful, but pleasing features of the landscape.

Mr. C. H. Mitchell, Consulting Engineer for the Dominion Water Power Branch, in designing a small power station to be situated near Banff in the Rocky Mountain Park, offered prizes to the students in the Department of Architecture of the University of Toronto for suggestions of an architectural treatment. There were fifteen designs submitted by the students, all of which have considerable merit and offer valuable suggestions to the engineer in his study of similar problems. The students of the University were all intensely interested in the solution of this problem, and the staff in charge have expressed themselves as feeling greatly indebted to Mr. Mitchell, and also to the Commissioner of Dominion Parks, Mr. Harkin, and to Mr. Challies, both of whom not only gave their consent, but were kind enough to loan photographs of the surroundings of the intended station.

The award of the competition was as follows:
First prize—A. C. Wilson.
Second prize—M. Denison.
Third prize—L. Husband.
Mention—H. Heaton and H. R. Watson.

It is perhaps needless to inquire if our readers concur in the opinion that certainly all those power stations erected for the public, especially those located near any tourist centre, should have some such local feeling and architectural character as represented by the illustrations appearing in this issue. The local governments, as well as the federal, could do much to educate and refine their citizens if more attention were paid to these matters.

THE GOOD ROADS CONGRESS IN MONTREAL.

The provisional programme of the Canadian and International Good Roads Congress to be held in Montreal during the week of May 18th, has just been issued. The following speakers, together with their subjects, are among those who will take part in the proceedings:

W. H. Connell, Chief of Bureau, Department of Public Works, Philadelphia, Pa.—"Important Considerations Entering Into the Selection of Pavements for Roads and Streets."

R. W. Brock, Deputy Minister of Mines, Dominion Government, Ottawa, Ont.—"Road Materials and Their Use."

Arthur H. Blanchard, Professor, Highway Engineering, Columbia University, New York—"Modern Bituminous Surfaces and Bituminous Pavements."

W. A. McLean, M.Can.Soc.C.E., Provincial Highway Engineer, Department of Public Works, Province of Ontario, Toronto, Ont.—"Highway Legislation."

A. T. Laing, Lecturer, Highway Engineering, University of Toronto,—"Technical Training of Highway Engineers."

Archibald Curry, C.E., City Engineer, Ottawa, Ont.—"Macadam Roads With Bituminous Tops."

E. A. James, B.A.Sc., Consulting Engineer, York County Highway Commission, Toronto, Ont.—"Maintaining Macadam Roads."

T. Hugh Boorman, Treasurer, The American Society of Engineering Contractors, New York City—"Modern Road Construction in the United States and England."

Hyndman Irwin, B.A.Sc., Editor, *The Canadian Engineer*, Toronto, Ont.—"The Relation of the Technical Press to the Good Roads Movement."

Paul D. Sargent, M.Am.Soc.C.E., Chief Engineer, State Highway Commissioner of Maine, Augusta, Me.—"Development of the State Highway System in Maine."

B. Michaud, Deputy Minister of Roads, Province of Quebec, Quebec City—"Highway System of the Province of Quebec."

Lieut.-Col. W. N. Ponton, Hon. President, The Ontario Associated Board of Trade, Belleville, Ont.—"Good Roads as a Factor in the Progress of Cities and Towns."

Dr. E. M. Desaulniers, Chambly County, M.L.A., St. Lambert, P.Q.—"Road Legislation of the Province of Quebec, Compared With Other Provinces."

Major W. W. Crosby, Consulting Engineer, State Highway Commission, Baltimore, Maryland; R. A. Meeker, Engineer, Department of Public Works, New Jersey; Jean de Pulligny, Chief Engineer, Bridges and Roads, and Director of the "Mission Francoise d'Ingenieurs aux Etats-Unis," and others, have also signified their intention of being present and of reading papers.

Among the exhibits will be that of the Department of Public Works of the Ontario Government consisting of a series of minature models showing the development of road building from the early Roman roads to the types in use at the present time.

LETTER TO THE EDITOR.

North Toronto Sewerage System.

Sir,—With reference to the article appearing in the Toronto Evening Telegram of April 28, 1914, giving some opinions of Mr. T. Aird Murray on the North Toronto sewerage system, I would like, as a civil engineer, to draw your attention to a statement made in one of the closing paragraphs.

Mr. Murray refers to the city engineering officials as being "wedded to the old-fashioned combined sewerage system, . . ." I beg to take objection to the use of the term "old-fashioned."

It is an idle question to ask whether the separate system is superior to the combined system. Under certain conditions the latter may be better, for others the former may be more suitable. More correctly speaking, all depends on the local condition, especially on the condition of the flowing river into which the effluent is led and on the method of purification adopted. Since both systems are nearly equal as far as traffic and public health is concerned, the question of cost only is decisive with respect to which is to be preferred in the locality under consideration.

As to the separate sewerage system, the public sewers can be easily adapted to the fluctuations of flow. They consequently can be designed with small cross-sections in which the velocity and cleansing action are relatively large and uniform. The cross-sections are usually calculated for maximum capacity running full. The filling up of the half section will then probably be obtained daily for some time. Deposits of putrescible matter seldom occur and these can be easily removed by regular flushing which, owing to the small cross-section, requires only a small amount of water. The formation of gas is very slight. In consequence of the frequent filling of the sewer an ample circulation takes place.

The storm sewers are carried on the shortest route to the nearest river or flowing water. By avoiding all long routes better grades and correspondingly smaller cross-sections are obtained. At the same time, the rain water pipes can be laid at smaller depths as they have not to drain deep cellars.

For the separate system the surface water is carried off either completely or partially. The saving is important by the omission of storm sewers. As soon as nuisances are caused to the traffic by the superficial removal of the rain water, or nuisances of any other kind are created, a new layout of a storm sewerage system can always be effected.

The separate system is always an advantage if the stream into which the effluent is to be discharged can be reached by means of short sewers, while the combined flow, on the contrary, has to be conveyed for a long distance on a flat grade. The route of transportation of the large quantities of storm water is, in this case, shorter with the separate system. The long sanitary sewers having only small cross-sections, thus the cost of removal per unit of quantity of sewage (storm and sanitary flow) is less than the removal in a common conduit.

Likewise, the separate system is preferable if the sewage has to be pumped to a higher elevation while the storm water runs off by gravity on a natural grade. A further advantage is that the house connections in the separate system for the conveyance of the sanitary flow are not liable to be backed up by heavy showers in the sewers which may be of value in flat districts.

In the case where the storm sewers cannot be carried to rivers closely located, the twin sewers of the separate system are always more expensive than the simple combined system, and the latter is to be preferred.

A great factor in favor of the separate system is indeed the easier purification of the sewage in consequence of the more uniform condition.

However, it is often necessary to lay out a complete scheme on the separate and on the combined system in order to compare the two. Here it is necessary to bear in mind that the house connections of the separate system cost twice as much as those of the combined, apart from the fact that the construction requires more careful attention necessary to prevent the storm water finding its way into the sanitary sewers.

From what I have said and in spite of the undeniable advantages of the separate system, there is no reason to call, as an adherent of one system, the other old-fashioned. Such a behavior shows narrow-mindedness and deserves no consideration. The cost of the sewerage system, the method of purification to be adopted, and the condition of the flowing stream are the only decisive momenti.

Therefore, if a combined system is installed, the objectors can only conclude that one has considered more the experience and ability of an engineering expert than the inciting myopia of would-be engineers.

ERWIN KOHLMANN,
Dr.-Ing., Dipl.-Ing.

Toronto, April 29, 1914.

[NOTE—The foregoing letter refers to an extensive sewage project recently recommended by Mr. R. C.

Harris, Commissioner of Works, Toronto, for that section of the city formerly known as the town of North Toronto. The scheme calls for a combined system, the estimated ultimate cost being $4,144,256. The improvement divides the district into two sections at Eglinton Avenue. In the section north of Eglinton Avenue it is proposed to construct lateral sewers to cost $422,000 and thirteen trunk sewers to cost $584,644. Two storm outlet sewers are provided, the cost of which is estimated at $366,275. The sewage disposal plant for this district will cost $305,900 and consist of a stand-by tank for the treatment of storm water, detritus tanks, Imhoff tanks, chlorinating devices, sludge-drying beds and sprinkling filters.

The sewage disposal plant in Section 2, will be similar to the above, but of larger capacity, and will cost approximately $400,000. The work in this section involves the construction of lateral sewers estimated to cost $390,000 and seven trunk sewers costing $648,000. Two storm outlet sewers will cost about $360,000, while a dry-weather-flow sewer to the disposal works is also proposed. It should be stated that the estimate of each disposal plant includes a site for future development and that each trunk sewer will have a superficial area exceeding four square feet.

In the interview to which Mr. Kohlmann refers, Mr. Murray, who designed the present system of sewage in North Toronto, criticises the expenditure of $4,000,000 on the proposed combined system. The present system was designed on the separate plan, to take domestic sewage only with a small proportion of roof water where necessary, but no surface water. Mr. Murray contends that the separate system is the only suitable one for the district, claiming that the purification point of view is one of the chief considerations relative to its sewage system as the practice of discharging sewage into the Don River must be continued for some time. In pronouncing the separate system of sewage as the ideal one for a suburban district such as North Toronto, which will probably be free from manufacturing industries, Mr. Murray alludes to the excessive cost of the project as outlined above and refers, as Mr. Kohlmann states, to the city engineering officials as being wedded to the old-fashioned combined sewage system. Hence Mr. Kohlmann's criticism.—Editor.]

A NEW STEEL SHEET PILING SECTION.

A new form of Lackawanna steel sheet piling section is now being rolled for use in 90-degree corners of rectangular cofferdams or retaining walls, either with the hook or guard on the outside. These rolled corners overcome the necessity of using specially fabricated and less easily driven corners. Moreover, they weigh less per lineal foot than the fabricated corners, and can be used wherever the conditions of load are not excessive. With the flexibility characteristic of this make of joint the two new corners will meet most requirements.

The Port Arthur city council has been approached by J. Stewart of Chicago with a request for a favorable consideration of a proposal for the location of a coal gas plant at Port Arthur. The matter is being considered by the industrial committee of the council

It has been reported that the Standard Oil Company has entered into an agreement with the Chinese government, or with Yuan Shih-Kai, the dictator president, for the control of the extensive oil fields of northern Shensi. The amount paid by the company for this concession is not known.

SEWAGE POLLUTION OF BOUNDARY WATERS.

THE investigation into the pollution by sewage of the boundary waters between Canada and the United States has received frequent mention in *The Canadian Engineer.* The whole subject is being well summed up by Dr. Allan J. McLaughlin, chief sanitary expert and director of field work for the International Joint Commission, in a paper to be read next week at the convention of the American Water Works Association, and published in the Journal of the Association for March, 1914. In December, 1910, Dr. McLaughlin was directed to investigate the sewage pollution of interstate and international waters with special reference to the spread of typhoid fever. In 1911 he completed a sanitary survey of the entire watershed of the Great Lakes on the United States side of the boundary. Briefly the conditions found were as follows:—

An excessive prevalence of typhoid fever, especially in the winter and spring months, punctuated at intervals by explosive epidemics. This excessive prevalence of typhoid fever especially in the winter and spring months was due in greatest measure to the unrestricted discharge of sewage into interstate and international waters used as sources of public water supplies. Disaster followed the use of this sewage polluted water for one of two reasons, either a failure to purify or the inefficiency of the attempted purification.

The delusion that water from the Great Lakes or their connecting rivers needs no purification has been cherished for years in our cities and even with our disgraceful record of waterborne typhoid and the lessons of numerous disastrous epidemics, it is still no easy task to convince municipal officials that purification of these waters is necessary.

The remedies suggested by the writer at that time were:—

1. Safe water supplies, that is, water shown to be safe by daily bacteriologic examination.
2. Supervision and control of water supplies by the state to ensure efficiency and a safe effluent at all times.
3. Control of sewage discharge within permissible limits to prevent an unreasonable burden or responsibility upon filter plants.
4. Prevention of pollution from vessels.

In order to secure efficient and uniform results from the application of these remedies, he recommended that two sets of standards for water be formulated.

1. Standards for filtered or treated water.
2. Standards for raw water at the intakes.

In accordance with this recommendation in January, 1913, the U.S. Surgeon-General appointed a commission for the determination of a standard of purity for drinking water, and the report of that commission will soon be published. This report will furnish a minimum standard to which all common carriers, trains and vessels must conform to prevent the spread of disease in interstate traffic. This furnishes the first standard recommended. The fixing of the second standard or standard for raw water at the waterworks intakes is a much more complex problem. However, great strides have been made in this direction also.

A committee of the national association for the prevention of pollution of rivers and waterways, made up of Geo. C. Whipple, Edward Bartow, Geo. M. Wisner, H. W. Clark, and Dr. McLaughlin, studied the problem of standards in a general way and agreed upon certain fundamental principles which made a very good starting

point for more intensive studies. This brings us to the work of the International Joint Commission.

The term Commission is misleading, as this body is in reality a tribunal formed under the treaty of January 11, 1909, between Great Britain and the United States to prevent disputes regarding the use of the boundary waters and to settle questions now pending or which may arise hereafter between the United States and Canada, involving the rights, obligations or interests of either in relation to the other or the inhabitants of the other along their common frontier. In addition to their judicial powers the Commission, under Article IX. of the treaty, is empowered to investigate and report upon such questions as may be referred to it by the two governments. It is provided that such reports under Article IX. shall not be regarded as decisions of the questions and shall in no way have the character of an arbitral award under this investigative function.

The question of pollution of boundary waters was referred to the Commission by the two governments. The reference was in two sections, the first dealing with the location, origin and extent of pollution and the second dealing with remedies. The text of the reference was as follows:—

1. To what extent and by what causes and in what localities have the boundary waters between the United States and Canada been polluted so as to be injurious to the public health and unfit for domestic or other uses?

2. In what way or manner, whether by the construction and operation of suitable drainage canals or plants at convenient points or otherwise, is it possible and advisable to remedy or prevent the pollution of these waters, and by what means or arrangement can the proper construction or operation of remedial or preventive works, or a system or method of rendering these waters sanitary and suitable for domestic and other uses, be best secured and maintained in order to insure the adequate protection and development of all interests involved on both sides of the boundary, and to fulfil the obligations undertaken in Article IV. of the waterways treaty of January 11, 1909, between the United States and Great Britain, in which it is agreed that the waters therein defined as boundary waters and waters flowing across the boundary shall not be polluted on either side to the injury of health or property on the other?

The Commission took up first the question of location, origin and extent of pollution. At the Detroit session February 20, 1913, Dr. McLaughlin was placed in charge of the investigation as chief sanitary expert and director of field work. Associated with him on the Canadian side were Dr. John W. S. McCullough, Chief Health Officer of Ontario, and Dr. John A. Amyot, Professor of Hygiene, University of Toronto. Canadian laboratories were established at Fort Frances, Port Arthur, Sault Ste. Marie, Sarnia, Windsor, Amherstburg, Port Stanley, Fort Erie, Niagara-on-the-Lake and Kingston, Ontario, and Montreal. American laboratories were established at Port Huron, Michigan, Detroit, Michigan; on U.S. Revenue Cutter "Morrill"; Buffalo, New York; Youngstown, New York; Clayton, New York; and Van Buren, Maine.

In the interest of economy and efficiency it was deemed wise to utilize such established governmental agencies as might be available for the field investigation. Accordingly the co-operation of the United States Public Health Service, the Provincial Boards of Health of Ontario and Quebec, the State Board of Health of Michigan, and the Department of Health of the State of New York was secured and was of very great value to the Commission in carrying out the work.

The work extended from the Lake of the Woods through the entire chain of the Great Lakes and St. Lawrence River to the St. Johns River on the Maine—New Brunswick border. Field work began in April and terminated November 1. There were over 1,400 sampling points and over 19,000 samples taken and examined bacteriologically. The report presents as indices of pollution the average number of the colon bacillus per 100 cc. of water and the number of bacteria per cubic centimeter of water. The results of the investigation are shown by averages in concise form for each sampling point and cross-section by tables and colored maps. In addition, diagrammatic representation is employed to show the degree of intensity of the area of pollution in each section of the boundary waters. In certain localities on the Great Lakes and in all their connecting waters dangerous sewage pollution was shown to exist, but the bulk of the Great Lakes waters remains in its pristine purity. The investigation shows that the colon bacillus is practically never present in unpolluted waters, and that the normal bacterial content of Great Lakes water is less than 10 per cubic centimeter. Great Lakes water is classified tentatively into five classes in this report, from the relatively pure water through slight, moderate, serious to gross pollution. The sources of pollution in the order of their importance are sewage from cities, sewage from vessels navigating these boundary waters, and the inevitable pollution following rains and thaws. The distance pollution may travel in the Lakes was demonstrated also. At the mouth of the Detroit River and at the mouth of the Niagara River serious pollution extends normally more than 10 miles into the lakes and on occasion was found 16 to 18 miles from shore. The distances from the cities of pure water in the lakes, the enormous cost of long pipe lines, coupled with the engineering difficulties in placing intakes beyond a 70-foot depth, make it impracticable in most instances to secure pure water from the lakes without treatment. The present position of intakes is such that there is not a single municipality using lake water which can be said to possess a safe water supply without treatment.

As might be expected, the areas most grossly polluted are in the connecting rivers upon which large cities are situated. The pollution from vessels renders the St. Mary's River above the cities of Sault Ste. Marie unfit as a source of water supply without treatment, and vessel pollution combined with the sewage from the cities of Sault Ste. Marie cause gross pollution of the St. Mary's River from the Sault to Neebish Island.

Because of sewage pollution there is no point in the St. Clair River from which a safe water supply could be secured without treatment.

The Detroit River is polluted from Lake St. Clair to Sandwich sufficiently to make the water an unsafe source of water supply. From below Sandwich to its mouth the Detroit River is grossly polluted from shore to shore.

Gross pollution in the Niagara River extends along the American shore from Buffalo to Strawberry Island, throughout the entire Tonawanda Channel, and below the Falls gross pollution extends from shore to shore throughout the entire river and for miles out in Lake Ontario.

Investigation of the St. Lawrence River (Lake of the Thousand Islands) was made at two distinct seasons. The

results obtained in April showed a slight degree of pollution. The results obtained in August showed a greatly increased pollution obviously due to the increase in summer resort population and to the sewage discharge from vessels.

The report of the field work gives an accurate survey of the origin, location and extent of pollution and completes the first half of the reference. The Commission is about to take up the second half of the reference which relates to remedies for pollution.

Dr. McLaughlin's suggestion to the Commission in regard to proceeding with the second part of the reference consisted of three steps:

1. Secure the opinions of the most eminent sanitary engineers by submitting a list of questions. These opinions would form a sound basis for formulating a general policy and possibly some general minimum requirement.

2. Public hearings at which the municipalities could present their cases including expert engineering testimony, plans and projects.

3. Employment of expert sanitary engineers for the formulation of special standards for each waterway in excess of general minimum requirements depending upon local conditions and necessities.

It is probable that the Commission will proceed somewhat according to this outline. In so doing and in carrying out the third step formulation of special standards, we will realize the second of the essentials which are necessary for the protection of the public health, viz.: A standard for the raw water at the intakes.

The standard for raw water at the intakes in each locality seems to be the only means by which an equitable adjustment can be secured between the two agencies in producing safe water, viz.: water purification and sewage treatment.

In concluding his paper, Dr. McLaughlin strongly accentuates to the American Water Works Association the necessity for safe water supplies and he enumerates several cardinal necessities to be observed in the purveying of water to the public.

There has been entirely too much confidence in untreated surface supplies. A surface supply from an inhabited watershed is rarely safe without treatment and can only be said to be safe when daily bacteriologic examination shows it to be free from pathogenic or intestinal germs. To ensure safe water bacteriologic control is just as much a necessity for water purification plants as for untreated supplies. With a polluted source the mere installation of a purification plant does not guarantee safe water. Even if perfect in design and construction unless efficiently operated and controlled a safe effluent need not be expected. Reference was made to filter plants designed by very capable engineers—perfect mechanisms which if properly operated would produce safe water—placed in the hands of an assassin who was a promoted stoker and absolutely ignorant of bacteriology or chemistry.

Another point brought out referred to the adjustment of the balance between water purification and sewage treatment. He has seen very good filter plants struggling with a raw water which imposed an unreasonable responsibility upon the plant. A safe effluent under such conditions was secured at the price of eternal vigilance. filter plants are not infallible and their operators, even when skilled, are only human. Dr. McLaughlin believed a decent raw water should be made available for all plants and where necessary treatment of sewage should be carried at least far enough to secure this result.

The greatest obstacle to proper operation and control of plants has been the difficulty of securing the right man to place in charge of the plant. The best type of man for this position is a graduate in sanitary engineering. He will not only be conversant with the mechanical details of the plant, but will be able to adjust his chemicals according to the constituents and needs of the raw water. Most important of all, he will be able to make daily bacteriological examinations to determine the efficiency of purification. Nearly all the disasters due to sewage-polluted water supplies which have occurred were due to lack of daily bacteriological knowledge of the public supply or the inefficient operation of plants by unskilled men. The employment of such a graduate is economy even in small cities. There may be cases, however, where it is impossible, for economic reasons, to pay the necessary salary. In these cases local men must be employed, and trained to do the work. Here the Board of Health will find a very useful function. The State authorities could supervise the installation of a small, inexpensive laboratory equipment in small plants and give instruction to the local man in making the necessary water examinations. Whenever possible, however, young graduates of sanitary engineering schools should be employed; and such men are well worth their salary, considering the saving in the economical adjustment of chemicals and fuel costs made possible by intelligent supervision. The greatest asset, however, to be credited to skilled operation is the saving of human life effected and the satisfaction of knowing that safe water is being furnished every day.

The Mississippi River Commission, which met at St. Louis, Mo., on April 15, agreed to recommend that Congress appropriate $12,000,000 for the improvement of the river next year.

Approximately 500 mineral claims have been staked at Beaver Lake and registered at the Dominion land office at Prince Albert, Sask., since the rush to the goldfields commenced a few months ago, and 350 powers of attorney have been taken out.

At a general meeting of the Standard Oil Company of Canada, held on April 16, in London, Eng., resolutions were agreed to for the reconstruction of the company and the registration of a new company under the name of the Coatsworth Natural Gas Company, Limited. The capital of the new company will be £35,000.

The Commission of Conservation at Ottawa, acting in co-operation with the provincial governments, has been making an extensive investigation into the water-powers of the western provinces. Field parties have covered practically all the territory in these provinces, particularly in British Columbia, and a report will be issued shortly, giving full data, including the results of systematic stream measurements. The information respecting the water-powers in the eastern provinces was published in a report by the commission two years ago.

The following items of expenditure were given in the summary of capital expenditure published in the report for 1913 for the corporation of the city of Vancouver, B.C.:—

General Fund—	
Street and lane improvements	$582,322.86
Sewers	[illegible]
Bridges	217,674.96
Rock crusher and bunkers	10,167.15
Waterworks	678,416.40
C.P.R. subway	21,728.33
Local Improvements:—	
Cement walks and curbs	[illegible]
Pavements	[illegible]
Street widening	427,040.64
Opening lanes	17,899.13
Ornamental street lighting	38,608.21
Macadam roadways	832.85
Wooden curb	[illegible]
Resurfacing	[illegible]
Street and lane extensions	38.40

THE USE OF ELECTRICITY IN THE STEEL HARDENING ROOM.

By R. H. Cunningham, B.A.Sc.,
General Manager, Canadian Hoskins, Limited,
Walkerville, Ont.

IN April 16th, 1914, issue of *The Canadian Engineer* the writer attempted to present in a general way the heat treatment operation of steel known as the process of hardening, and to explain its effect in relation to the varying composition which the material may have. The article referred to the critical temperatures which were associated with steels of different carbon content, and touched upon the theory governing the peculiar phenomena and characteristics one found in connection with the process. The necessity of accuracy for good results in the hardening of carbon steel was emphasized, and it is the purpose of this article to describe a practical means of determining the correct temperatures upon which these good results depend.

The necessary apparatus for the process which the writer has in mind consists of a small electric furnace in which to heat a specimen of the steel to be tested, a special thermo-couple pyrometer for indicating the temperature of this specimen throughout its range of heating, and a specimen itself, properly shaped for clamping to the thermo-couple. The apparatus for this purpose, as shown in Fig. 1, illustrating what is known as the Hoskins' recalescent outfit has a crucible chamber 2 1/16 in. in diameter and 2½ inches deep. Heat is produced by means of the resistance offered to the passage of an electric current through the "resistor" or heating element. This "resistor" is of a special metal in the form of wire which is wound in close contact with the chamber

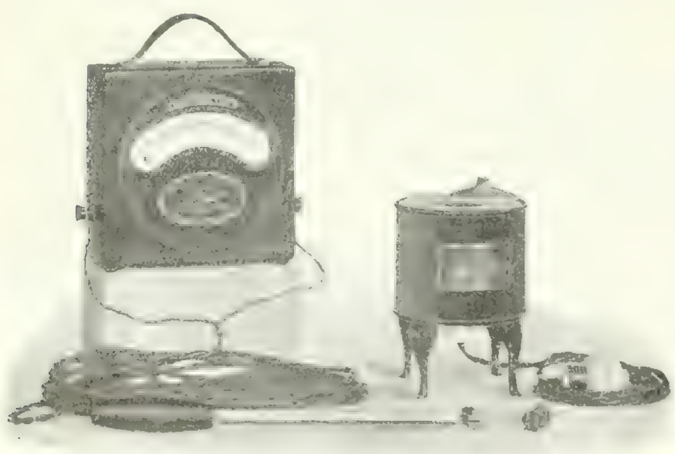

Fig. 1.—Recalescent Outfit. Note the two test specimens of steel, one fastened to couple.

lining. The furnace is designed so that it can be used on standard lighting circuits to which ready connection is made by means of a twin-conductor cord and lamp plug. In operation, it consumes 3½ amperes at 110 volts and is capable of producing a chamber temperature of 1,000° C. (1,832° F.) which is considerably higher than any required by a carbon steel.

The pyrometer of the outfit is of the thermo-electric type. This instrument embraces a thermo-couple, connecting leads and indicating meter. The thermo-couple is of small wire so as to respond quickly to any slight variation in temperature. The welded end of this couple is slightly flattened to enable the making of a good contact between it and the specimen of steel. The meter is portable and indicates temperatures up to 1,400° C. (2,552° F.).

The specimens of the steel to be tested should be small so as to heat quickly and uniformly. A well-formed specimen is made with two duplicate parts, each 1¼ inches long by ½ inch wide by ¼ inch thick. These pieces are clamped, by means of two ⅛ inch bolts, one on either side of the welded part or extreme end of the thermo-couple. Care is taken to form a tight contact,

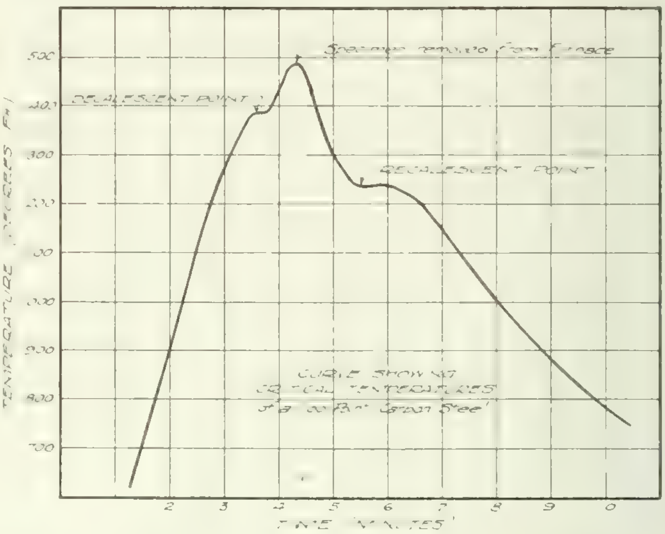

Fig. 2.—Heating-cooling Curve, Showing Location of "Critical Temperatures."

though not to cause an undue strain on the couple. The dimensions here given for the test specimen are not essential, though convenient; any pieces which will permit of tight contact with the thermo-couple and of ready heating in the furnace chamber, may be used.

Method.—With the specimen fastened to the couple, as just described, the furnace is connected in circuit and the cover placed over the chamber opening. The temperature within the chamber rises steadily. When it becomes 925° C. (1,700° F.) the end of the couple, with specimen attached, is inserted in the chamber.

The steel specimen rapidly heats up, its temperatures being constantly the same as that of the welded junction of the thermo-couple, due to the intimate contact between them. This temperature, indicated by the meter, will rise uniformly until the "decalescent" point of the steel which is being tested is reached. At this temperature the indicating needle of the meter becomes stationary, the added heat being consumed by internal changes instead of by increase of temperature. These changes completed the temperature again rises, the length of the elapsed period of time depending upon the speed of heating. With the furnace temperature kept constant at the initial point here given (925° C. or 1,700° F.), this "speed of heating" will be such as to allow of readily observing the pause in motion of the needle. The temperature at which this occurs should be carefully noted as it is the decalescent point.

To obtain the lower critical point, the temperature of the piece is first raised above the decalescent point by about 40° C. (104° F.). In this condition it is removed from the furnace and rested on top to cool. The decrease of temperature is at once noticeable by the fall of the meter needle. At a temperature somewhat below the

decalescent point, varying with the composition of the steel, as previously mentioned, there is again a noticeable lag in the movement of the needle. The temperature at which this ceases entirely is the recalescent point. Immediately following there may occur a slight rising movement of the needle, as explained under "Theory" in the preceding article already referred to.

During these intervals of temperature lag, on both the heating and cooling of the steel, there may occur a small fluctuation in the temperature. In order to get results that are comparable, a definite point in each of these intervals should be considered, each time a test is made. Hence both the decalescent and recalescent temperatures are taken as the points at which the needle first becomes stationary.

As all operations of heat treatment of a steel centre around its critical points, the importance of knowing these exactly is realized. To make certain, each test should be checked by a second reading. The time required for this is small. A close arrangement of two succeeding readings will give assurance of the correctness of the determination.

Results Obtained from Sample Specimens.—In order to show graphically the necessity of working carbon steels at the proper temperature points, here dwelt upon, a series of specimen pieces of the same steel were treated at different temperatures. The steel used contained exactly 1% of carbon. A number of test specimens were made of this from different parts of the same bar.

First, the critical points of this steel were determined. With the test furnace at a temperature of 935° C. (1,700° F.) the specimen, fastened to the welded junction of the thermocouple, was inserted in the chamber. When its temperature had exceeded the decalescent point of the steel by 100° F., or at 805° C. (1,480° F.) it was removed from the chamber and allowed to cool. Temperatures were recorded throughout both the heating and the cooling. In Fig. 2 these values have been platted. The curve shows graphically the location of the critical points, and also the retardation of motion which precedes these and the slight fall or rise of temperature, as the case may be, which follows them.

With this data obtained, 7 specimens of the same steel were heated, in the electric furnace, each to a different temperature. As these pieces were removed from the furnace they were immediately quenched in water. The temperature of the quenching bath was held constant at 45° F. These hardened pieces were then broken at right angles. The fractured surface of each was photographed under a microscope. These photographs are here produced in the same size as the originals—in Figs. 3 to 8 inclusive. Due to magnification, each of the first five of these represents a portion of a circular area of the actual steel, 0.05 in. in diameter; in the last two, of 0.1 in. in diameter.

An inspection of these shows at once the serious effects on its structure—and hence on its strength—of overheating a piece of steel. The specimen shown in Fig. 3 is very badly "burned," as evidenced by the extreme coarseness of its grain. The specimen in Fig. 4, hardened at 150° F. lower temperature, shows less coarseness, though still badly burned. The succeeding specimens show a gradual improvement, as the temperature at which they were hardened approaches the decalescent point of the steel. Fig. 8 shows a specimen which was quenched, just after the hardening change in its structure had become complete, at 5° F. above the critical temperature. The very fine grain and closely woven texture of this fracture show a properly hardened steel, one which has both the desired hardness and the maximum of quality.

Fractured sections of carbon steel, carbon content 1%. (Figs. 3 to 7 inclusive magnified 50 diameters. Fig. 8 magnified 25 diameters).

The specimen shown by Fig. 9 was hardened just as the temperature reached the decalescent point. This illustration shows the direction in which the hardening moves, namely, from the exterior toward the interior. This would naturally be expected as the temperature of the surface—which is exposed directly to the source of heat—reaches the critical point first. As seen in the illustration, the structural change has been completed only in the surface layer—toward the corner—of the specimen. Here the grain is fine, the steel hardened,

while the interior is still in the unhardened state as evidenced by its coarser grain. This condition indicates the necessity of heating the piece uniformly.

While 1,900° F., the temperature at which the specimen of Fig. 3 was hardened, represents a very excessive heat, yet it is not infrequent that carefully machined parts are ruined by overheating to even this degree. The practice of guessing at hardened temperatures can only result in uncertainty at the best. Yet, by use of the apparatus here described, the correct hardening temperature of any carbon steel can be exactly determined.

The hardening of carbon steels for the highest quality and greatest saving entails, then, three things: First, a definite knowledge of what constitutes the correct temperature at which to harden the steel. The fundamental theory and facts underlying this have been presented in the article in April 16th issue.

The second point necessitates a positive means of accurately determining this hardening temperature for any carbon steel. The outfit described above is a direct and economical answer to this. The simplicity of the apparatus, its ease and certainty of operation, compel attention to its use. It makes possible the maximum quality in the finished steel, and the greatest saving in production cost.

(Magnified 25 Diameters.)

Fig. 9.—Fractured section of a 100-point carbon steel quenched just at its decalescent temperature (1380° F.), showing uneven hardening due to lack of uniformity of heat penetrations.

The third consideration is that the correct hardening temperature, once determined, is actually carried out in the hardening work. A simple and effective way of doing this is by checking the temperature of the hardening furnace by means of a pyrometer. For this purpose, the meter of the recalescent outfit may be used in connection with a second and heavier thermo-couple.

When there is a large quantity of work to be hardened, economy dictates a permanent installation of pyrometers. The convenience of such installations is manifest. A thermo-couple is placed in each furnace. A number of these, from three to sixteen, depending upon individual conditions, are connected by wire leads, through a selective switch to one meter. By a turn of the switch, the temperature of any furnace may be read at once from the meter. This makes it possible for the foreman, at a single point, to know definitely the temperatures of all of the hardening furnaces in use. It eliminates all guesswork, makes responsibility absolute and results positive.

Temperature Measurement.—The majority of industrial operations involving the production or utilization of heat require some reliable and practical means for measuring the intensity of heat. In some cases this is essential because the successful outcome of the operation depends upon a particular temperature. In others the cost of generating heat is the important consideration and it is then a matter of economy to know the temperature so that energy will not be wasted in generating surplus heat.

These well-known facts have been widely disregarded in industrial plants, in spite of resulting inefficiency and waste, because of a general lack of confidence in many of the devices which have been available for measuring temperatures where ordinary thermometers are not suitable.

This unsatisfactory state of affairs has existed because so many of these devices are totally unsuited to industrial work. They are either of the strictly laboratory variety, too fragile and expensive for shop use, or, if strongly enough built to stand hard usage, are correspondingly inaccurate and unreliable.

The pyrometer that has been developed by Hoskins Manufacturing Company will operate up to 2,300° F. for continuous service and 2,500° F. for intermittent use, and will handle the great variety of operations requiring heat. This is from 500 to 600° higher than recommended for any other type of base metal type pyrometer.

The Thermo-Electric Pyrometer.—These pyrometers are of the thermo-electric type, it being the most widely adaptable and practical of all temperature measuring devices for temperatures above the range of ordinary thermometers and up to approximately 1,370° C. (2,500° F.).

Briefly, the chief advantages of the thermo-electric pyrometer are that it gives direct readings of temperatures above the range of thermometers and that temperatures of one or many points may be taken at a central location distant from the source of heat.

The limiting low temperature for which the thermo-electric pyrometers are recommended is, under average industrial conditions, near 100° C., although they can be used to advantage below that temperature when proper provision is made for keeping the "cold-end" temperature constant.

For the benefit of those who are not familiar with pyrometers and to make clear the purposes and advantages of certain late improvements, the following explanation is given. The principle upon which the thermo-electric pyrometer operates is the measurement of a current of electricity generated by the action of heat on the junction of two dissimilar metals.

The thermo-electric pyrometer consists of two essential parts, namely, the thermo-couple and the meter. The thermo-couple, which generates the electric current, is composed of two wires of dissimilar metals connected at one end. This connected end of the couple is called the "hot end" and is placed in the furnace or heated space, the temperature of which is to be measured. Except at the hot end, the two wires, or elements, do not touch. The free ends are known as the "cold end" of the thermo-couple from the fact that this end of the couple is always kept away from the heat, and generally at the temperature of the outside air. When the hot end of the thermo-couple is heated it generates an electro-motive force, the intensity of which is determined by the difference of the temperature of the hot-end and the temperature of the cold end.

The meter is the indicating part of the pyrometer. It is connected by means of a pair of copper lead-wires to

the cold end of the thermo-couple and measures the current caused to flow by the electro-motive force of the thermo-couple.

Instead of indicating the value of the current in electrical terms the meter is calibrated to indicate directly in degrees F. or degrees C., as may be desired.

In order that the meter will indicate the actual temperatures of the hot end and not merely the difference between the temperature of the hot end and the cold end, the starting point of the meter must be set to agree with the temperature of the cold end. As the most convenient temperature for the cold end is that of the average room, the starting point or "zero setting" of the meter is usually at 25° C. or 77° F. for calibration.

Unless some special provision is made for the purpose, it is obviously impossible, in practice, to keep the cold end constantly at the room temperature for which the meter was calibrated. This variation is considerable and introduces an error which has been one of the principal objections to the thermo-electro pyrometer. The so-called cold end error has been a serious obstacle to the use of the thermo-electric pyrometer, especially on large permanent installations. In the above instrument this has been practically eliminated by means of the zero adjuster and cold end water jackets.

Before the zero adjuster was developed it was necessary, in order to obtain the correct temperature, to add or subtract from the meter reading the difference between the cold end temperature and the zero setting. With the zero adjuster it is only necessary to reset the meter zero or starting point to agree with the thermo-couple cold end temperature, whereupon the meter will automatically read the correct temperature of the hot end.

When the pyrometer equipment consists simply of a meter and a single thermo-couple, the zero adjuster alone is sufficient to correct for the thermo-couple cold end temperature variations. It is seldom that the cold end temperature is subject to rapid variations and it is thus a very simple matter to occasionally reset the meter zero in agreement with the cold end temperature, thereby obtaining correct temperature indications by the meter.

It is when the installation consists of a number of thermo-couples all connected through a selective switch to the same meter and when the various couples are subject to different cold end temperatures that a cold end water jacket is necessary, since it would, of course, be impracticable to reset the meter zero to agree with the cold end of each thermo-couple in turn.

The function of the cold end water jacket is to keep the temperatures of the cold ends of a number of thermo-couples at approximately the same temperature. With this accomplished, but one setting of the meter zero is necessary, regardless of which couple is connected to the meter when the reading is taken. The manner in which the cold end water jacket accomplishes its purpose will be made clear by the following description of the Hoskins cold end water jacket..

This water jacket consists of a coil of seamless steel pipe covered with a layer of heat insulating material. The coil is of sufficient diameter to permit the insertion of the thermo-couple spool. Six or less of these jackets are connected in series to a water line having sufficient pressure to keep a continuous flow of water through the system. A thermometer is inserted in the pipe before the first jacket and another after the last one of the series. These thermometers indicate the temperatures of the water as it enters and leaves the jackets and the mean of the two temperatures is taken as the temperature at which to set the zero. As the increase in the water temperature is never over 10°, the maximum error would only be 5°, which is sufficiently accurate for practical purposes. With this system it is seldom necessary to adjust the meter zero more than once or twice a day.

Protecting Tubes.—The choice and use of the proper protecting tubes has much to do with the success of the thermo-electric pyrometer. At high temperatures the elements of the couple become somewhat soft and susceptible to the action of gases. By protecting the couple with a tube of the right type it is possible to prevent or delay these injurious effects and lengthen the life of the thermo-couple elements. The protecting tube also protects the couple against mechanical injuries.

Quite contrary to the general impression, it is not oxidizing but reducing gases which seem to have the most detrimental effect on the thermo-couples. An oxidizing gas causes a gradual deterioration of the couple which can be observed and which permits the user to provide another thermo-couple before it breaks down. But with reducing gas, the action may be sudden and local and frequently causes a couple in good condition to break shortly after being put in the heat. It is this fact in connection with the wrong choice or entire lack of tubes that has caused much unnecessary dissatisfaction with thermo-electric pyrometers.

For temperatures up to 1,200° F. a good steel tube will give excellent satisfaction, in ordinary furnace gases. From 1,200 to 2,000° F. a nickel chromium protecting tube should be used. However, above 2,000° they are not very satisfactory and a very heavy seamless steel tube should be used.

Calibration.—In plants where a large number of pyrometers are used it is advisable to have an easy and dependable way by which to periodically check the accuracy of the various thermo-couples and meters. The most satisfactory way to do this is to use an accurate check pyrometer with which the installed pyrometers can be compared under service conditions.

The method of checking is to place the thermo-couple of the check pyrometer in the same protecting tube with the service couple, being careful to see that both couples are inserted to the full depth of the protecting tube. By then comparing the readings of the two meters the accuracy of the service pyrometer can be determined. In order that there may be sufficient room for both the service and the check couples, all protecting tubes should have an inside diameter of at least ¾ inch.

The type of pyrometer best adapted and most used for checking is the portable instrument. They should, of course, be very accurate. In order that it may be kept in this condition it should be used for no other purpose than checking and should be calibrated occasionally.

For low reading pyrometers the calibration may be done by placing the thermo-couple in a heated oil bath and comparing the readings of the meter with those of a high-grade mercury thermometer, having a range up to 150° C. (300° F.). The vessel for holding the oil should be approximately 6 in. deep by 4 to 6 in. in diam., and may be heated by a gas burner or electric hot-plate. Constant stirring of the oil should be done to insure a uniform temperature throughout. Any oil having a high flash point, or some of the waxes such as paraffine, beeswax, etc., may be used.

For calibrating pyrometers for temperatures above red heat, the welded or hot end of the thermo-couple should be covered with a tight winding of No. 14 or No. 16 B. & S. gauge standard melting point wire. The

couple should then be inserted in a tube furnace similar to the electric furnace shown in Fig. 1, with the welded end of the couple approximately in the centre of the furnace. The furnace should be up to heat before inserting the couple and should be kept at a temperature approximately 100° F. higher than the melting point of the calibrating wire. The pointer of the meter will then move up the scale with a gradually decreasing speed until the calibrating wire begins to melt, when the pointer of the meter will come to rest. After the calibrating wire has melted the pointer will again move upward. Pure copper wire, under oxidizing conditions, melts at 1,065° C. (1,949° F.) and pure zinc wire at 419° C. (786° F.). In order to have a strictly oxidizing atmosphere, an open end electric furnace should be used for calibrating work.

In using this method of calibration, care should be taken not to have the furnace temperature too far above the melting point of the calibrating wire, or the pointer will move so rapidly that the melting will be of such short duration that the holding point may be missed.

A very satisfactory way of calibrating pyrometers is by using the freezing points of melted salts as follows:

Pure common salt, Na Cl., is melted in a pure Acheson graphite crucible in an electric furnace. When the salt has been raised to a temperature of 100 or 200° F. above its melting point, the bare welded end of the thermo-couple is inserted in it to a depth of from 2 to 3 in. The crucible is then removed from the furnace and allowed to cool. The pointer on the meter will drop gradually until the salt begins to freeze, when it will stop until the salt is frozen. The freezing point of pure salt may be taken at 800° C. (1,472° F.). Before further use, the couple end should be washed clean in hot water to remove all traces of the salt, otherwise the couple will deteriorate rapidly, especially when heated considerably above the melting point of salt in an open furnace.

When calibrating pyrometers, care should be taken to see that the zero setting of the meter is in agreement with the cold end of the couple.

When the pyrometer is found to be reading too high the correction is made by increasing the adjusting resistance; and if reading too low, the resistance is decreased. The adjusting resistance is No. 26 B. & S. gauge wire of low temperature coefficient. In changing this resistance the connections should always be carefully soldered and the different turns insulated from one another.

Changing the resistance on the couple spool should not be attempted by the user unless he thoroughly understands, and has had some experience at, such work.

The following table gives the latest available data by the Bureau of Standards on certain substances which may be used for calibrating pyrometers:

Water boils at	100° C.	(212° F.)
Tin freezes at	232° C.	(450° F.)
Zinc freezes at	419° C.	(786° F.)
Common salt freezes at	800° C..	(1472° F.)
Copper, in oxidizing atmosphere, freezes at	1065° C.	(1949° F.)

Among the orders recently placed with English firms, figures an oil tank steamer of about 3,800 tons gross and about 365 feet in length for the Australian Government, to be built by Swan, Hunter and Wigham Richardson.

It is reported from Fredericton, N.B., that the residents of Granite Hill, Bear Island, Upper Queensbury and the districts on the other side of the St. John River in that vicinity are moving again to have a steel highway bridge built across the river at Bear Island.

THE CLAYWORKING INDUSTRY IN NEW BRUNSWICK.

In a report by Joseph Keele on the clay and shale deposits of New Brunswick the geological survey branch of the Department of Mines, Ottawa, has just published some very interesting information. The report covers work done in that province by the Geological Survey during 1911 and 1912. A chapter is devoted to the extent at present of the clay industry, and from it we make the following extracts:—

Up to the present time the clay deposits of New Brunswick have only been developed to a very limited extent.

Wooden construction prevails, to the exclusion of almost all other kinds, except in the business portions of the cities and towns, because lumber has hitherto been plentiful and cheap in the province.

The danger from extensive fires is always present when wooden construction is so freely used in closely-built communities. This was evident in the total destruction of the town of Campbellton by fire during the summer of 1910. Since then, the demand for structural clay wares is increasing, but they are not yet used as largely as they might be, because everything except common brick has to be imported.

New Brunswick possesses in its Carboniferous rocks, certain shale beds, adapted for making those higher grades of clay wares which cannot be produced in the Provinces of Quebec or Ontario, where these raw materials are absent. Clayworkers will probably find it to their advantage to locate works for the production of materials, not only for home consumption, but also for export.

Proximity to markets, although desirable, is not so essential to manufacturers of the higher grades of clay wares, such as face bricks, paving bricks, sewer-pipe, electrical conduits, fireproofing, etc., as these materials are frequently transported for long distances. A plant equipped for a large output of common brick can only be maintained close to cities, where the demand for them is constant during the greater part of the year. These plants frequently represent a considerable expenditure of capital, being furnished with artificial driers, continuous kilns, and machinery driven by steam or electric power. The surface clays can be worked in a primitive manner, with a small outlay of capital, to suit the demands of small towns or rural communities. Such plants are able to maintain their position, because the price of common brick would not pay the cost of carriage from large centres where their manufacture is carried on more scientifically.

When the need for underdraining the cultivated areas in the Province becomes more generally known, these clays will have a much wider application. Drain tile can be made from any of the surface clays. Tile are made from stiff mud, usually by an auger machine having a circular die, although different styles of plunger machines and also hand presses are used in their manufacture. They are made in sizes varying in diameter from 2 inches to 3 feet. Any means of drying and burning may be used with the smaller sizes, but the larger sizes require considerable care to prevent cracking. Contrary to the popular notion, it is not necessary for drain tile to be porous, so that they should be hard burned. Besides sufficient hardness, the important requirements for drain tile are straightness, uniformity of diameter, and smoothness of ends.

The only pottery in operation in the province is located at St. John. It is owned by J. W. Foley and Company, who manufacture butter crocks, teapots, jars, and flower pots. Most of the raw material is imported from the State of New Jersey.

The following details concerning the clay-working industry of the present time in New Brunswick are briefly given.

Fredericton.—M. Ryan and Son are the only brick manufacturers at this city. The material used is a surface clay, of the estuarine type, somewhat similar in character to that worked in the Annapolis and Shubenacadie valleys of Nova Scotia. The clay is moulded in a soft mud machine, without any preliminary pugging, but nevertheless makes a good grade of brick. The freshly moulded bricks are hacked out on the ground to dry in the air, but since Mr. Keele's visit, Mr. Ryan has installed a steam drier. Burning is done in a patent double chambered downdraft kiln, each half having a capacity of 90,000 bricks. The brick settles 12 inches in 31 courses during the burning.

St. John.—Two brickyards are in operation in the vicinity of this city. The clays used are all similar, being evidently remnants of marine or estuarine deposits laid down at a slight elevation above present sea-level. The clays are smooth and plastic, and free from pebbles. Any pebbles found in the finished bricks have probably come from gravels overlying the clays. The brickyard of Mr. John Lee is located on Courtney Bay at the Little river. The material used here is a tough, reddish brown clay and worked to a depth of 6 or 7 feet below the surface. The brick clay rests on a very hummocky boulder drift, which crops out in a few places in the bottom of the pit. The clay, after being broken down from the bank, is dumped into soak pits along with some sand, and kept there for a day or so before going to the machine. Sand-moulded or, soft mud bricks, some re-pressed bricks for facing buildings, and field drain tile are manufactured. The freshly moulded bricks are placed on covered pallet racks and air dried. There are two down-draft kilns, two updraft case kilns, and one scove kiln. The output is 25,000 bricks per day during the season, which are mostly sold in St. John.

St. Stephen.—There are two brick yards in operation near this town, making soft mud brick and drain tile. The material used is taken from a terrace of marine clay which occurs along the valley of the St. Croix river. Mr. John Laming has made bricks here during the last 31 years. He uses a small stiff mud machine for making wire-cut brick for facing, and for drain tile. He also makes soft mud bricks, which form the greater part of his output. The demand for drain tile is intermittent; these are only made to order, and not stocked. The principal object of interest is the tiles with which the building is roofed. These tiles were made by Mr. Laming, 22 years ago, from the clay in his own pit. These tiles are S-shaped, and although not hard burned, are still quite intact for the most part.

Sussex.—The brickyard operated by Mr. John Heffer is situated a few miles north-west of Sussex. The material used is a stiff, reddish clay, from 3 to 10 feet in thickness, overlying boulder clay. A stiff mud machine driven by horse-power is used. The bricks are hacked out on the open ground to dry, and afterwards burned in a scove kiln. The burned bricks contain some scattered, small pebbles and clay lumps, showing the need of passing the clay through rolls, or through a long pug mill, to prepare the clay for the machine. As the clay is becoming too thin for working at this locality, the plant will shortly be moved to a fresh clay deposit in the neighborhood.

Moncton.—The brickworks are located at Lewisville, 2 miles from Moncton. The material made is a glacial clay situated almost at tide level, and underlain by boulder clay. The maximum depth of the clay is 7 feet. This plant is equipped with a stiff mud machine and steam driers. The burning is done in scove kilns. The brick clay also occurs at various points around the city of Moncton, but is worked only at this locality at present.

Chatham.—There are two brick plants in the neighborhood of Chatham, owned by the W.S. Loggie Company. The plant at Nappan river uses a stratified, reddish clay, about 12 feet deep, lying on bed-rock, to which is added about 10 per cent. of sand. Sand-moulded bricks only are made; they are dried on pallet rocks, and burned in scove kilns. The bricks are set 36 courses high in the kiln, and the fuel used is dry spruce and tamarack. The output is hauled in wagons to the railway, and shipped principally to Campbellton. The working season lasts from the middle of May to December. An excellent deep red, hard, building brick is produced at these works.

The plant at Nelson is worked in a similar manner, and produces common brick of a quality very much like those at Nappan. This plant is better situated for transportation, as the bricks have only to be hauled over the bridge across the Miramichi river, to the railway station on the north bank.

On April 15, a delegation of 1,000 gathered at Ottawa, 700 of whom were from Montreal, and formed a permanent organization, whose purpose will be to promote the construction of the Georgian Bay Canal and furnish all necessary information for the recently appointed Government commission on the project; and to present to the Government arguments in favor of the immediate start of construction of the waterway.

The preliminary report on mineral production in Canada in 1913 shows a total value of production amounting to $144,031,047, an increase of 6.65 per cent. over the previous year, representing an average production per capita of $18.57, as against $18.27 in 1912 and $14.93 in 1910. The amount of coal produced was valued at $36,250,311, an increase of $[illegible]. The gold produced amounted to a value of $16,216,131, an increase of $3,567,337. The value of pig iron produced was $16,540,012, an increase of $1,989,013. There was a decline in the production of copper from a value of $12,718,548 in 1912 to $11,753,440 in 1913, and a decline in silver production from $19,440,105 to $18,084,012. Cement production increased from $9,106,556 in 1912 to $11,227,284 in 1913.

During the coming summer, a new railroad, thousands of miles in length, will be opened to traffic in Central Asia. It is a line which, linked to the existing Trans-Siberian Railroad at Krasnoyarak, crosses through the northern part of the province of Irkutsk, north of the Baikal Lake, through Eastern Siberia, and then through the Amur province, northward to the Amur river, to Kakhaborovsk, where it joins the already existing line that runs due south to Vladivostok. The surveys for this new line were already begun while the Russo-Japanese peace negotiations were in progress at Portsmouth, N.H., in 1905. It is built entirely on Russian territory; and, since the province of Eastern Siberia, and of the Amur, lying north of Manchuria, are perhaps more rich in minerals than any other portion of the world, the line bids fair to prove of the utmost economic importance. Much of the line has been laid through primeval forest, and through jungles where man had never set foot before, and where the temperature ranges from tropical heat in summer to 80½ below zero in winter; where the men had frequently to work for days and months standing almost thigh-deep in icy marsh. $2,050,000,000 have already been voted by the Duma for the construction of the road. Whether it will be sufficient or not to cover its cost is not known. It is intended that this new main line is to constitute the main trunk of a vast network of subsidiary lines. It will connect Moscow, over an all-Russian route, with the Czar's great stronghold on the Pacific, Vladivostok.

TRAVELLING CONCRETE PLANT.

A NOVEL concrete mixing plant with elevator tower and distributing chute is described in the "Canal Record" of Panama. It is being used for mixing and placing the concrete in the caisson shells and superstructures of the quay wall and pier now under construction at the Balboa terminals. Four units of the type are in use. The system has advantages of convenience, speed, and reduced labor cost.

Each unit consists of a hoisting engine, of approximately 20 horse-power, steamdriven; a ½-cubic yard portable mixer; an elevator for raising the concrete so that it can be distributed from a hopper by gravity; and a jointed distributing chute, for placing the concrete from the hopper. All of these items are mounted on a single flat car, resting on a 5-foot gauge track. The plant is advanced along the track with the progress of the placing. The sand, rock, and cement for the concrete may be handled to the mixer direct from cars coupled to the flat car in the rear, or from stock piles alongside the site of operations. In either case, they are carried to the mixer in wheelbarrows, over suitable staging.

The hoisting engine boiler furnishes steam for the mixer, and, by cables running over sheaves at the top of the elevator tower, raises and lowers the elevator car.

The elevator is a hollow timber framework, 4½ by 6 feet in plan. In the unit of which the side and front views are shown herewith, the tower rises to a height of 41 feet 3 inches above the deck line; in this type, the distributing chute is 52 feet long, with a distributing radius of 48 feet. In two other units of similar general design, the chute is longer, having a distributing radius of 78 feet. The elevation of the tower is determined by the requirements of distributing the concrete by gravity. In each case, the tower is braced by timber outriggers.

The elevator car is the body of an ordinary ½-yard Decauville dump car, mounted on trunnions. At an elevation determined by the length of the chute, it dumps automatically into a hopper which rests on a projection on the front side of the elevator shaft. The hopper is six by six feet in plan at its top, converging into juncture with the distributing chute. It has a capacity of about one cubic yard.

The distributing chute is of 14-inch steel pipe. It is in two sections of equal length, connected by means of a swivel joint. The upper section is known as the swivel arm, and the lower section as the nozzle arm. The upper section is connected with the hopper discharge by a swivel joint, and can swing to either side to a position at right angles with the axis of the flat car. The nozzle arm, swinging under the upper section, can describe a circle, the centre of which is the joint between the two sections. This combination of motions allows the mouth of the chute to be placed over any point in the semicircle described by swinging the chute with both sections extended in the same plane.

The method of supporting the chute is of especial interest. Both sections of the chute are supported by means of a pivoted latticework boom, projecting outward and upward from the front of the base of the elevator tower. The timbers of the boom pass on both sides of the upper section of the chute, allowing its support to be effected by the cross pieces. In addition, the boom passes far enough beyond the upper section to allow vertical guys to be attached to the intermediate joint, and slanting guys to be extended to the end of the nozzle arm. This does away with extraneous supports for the nozzle arm, and with the services of laborers in carrying it from point to point.

The system allows the mixing and placing of from 180 to 200 cubic yards of concrete per day from the ½-yard mixer. The arrangement of the chute allows the placing of concrete all over the semicircle in front of the mixer without the use of men with wheelbarrows, operating on runways laid over the reinforcement. These features are especially desirable in the pier construction, where it is important to complete a section, including a main girder and extending half-way to the girders on either side, in one day, in order that the concrete may harden in a complete unit.

In the new pier No. 1, each section is 29 feet 6 inches long by 75 feet 11 inches wide, and contains 191 cubic yards of concrete. One mixing unit will complete a section a day; but in case of breakdown, another unit can be withdrawn from caisson work and sent to supplement the placing for the pier. Each outfit is practically as portable as a wrecking crane.

The force for each unit consists of approximately 30 silver employees in charge of a white foreman. Twenty-five men are engaged in wheeling materials from cars or stock piles and supplying the mixer; one man is in charge of the mixer; one runs the hoisting engine; and three are out at the end of the chute distributing the concrete into the forms. This arrangement makes the labor cost very low.

The report of the Timiskaming and Northern Ontario Railway Commission for the year ended October 31st, 1913, shows a total mileage of the railway in operation at the end of that year amounting to 432.77, including 252.8 miles of main line, 80.64 miles of branch lines, and 99.33 miles of yards and sidings.

It has been decided to construct dams along the creek at Caron, Alta., for the purpose of protecting the infiltration pipe gallery and to increase the storage capacity of the Caron head works. Thev will be built of concrete and will be finished this summer.

In the two years, 1912-13, in British Columbia, the demand for structural materials—stone, cement, clay products, etc.—has not been so great latterly as in 1910 and 1911, so the value of the output of this class of non-metallic minerals was probably lower in 1913, and in the absence of data on which to base calculations no definite statement can be made. The marble-quarry in the Ainsworth Mining Division was worked and marble was shipped from it. Near Victoria, on Saanich Arm, a second cement manufactory was started, and near Princeton a beginning to produce cement was also made, but in neither case was a large output made. The Vancouver-Portland Cement works at Tod Inlet continued to make an important production. The destruction by fire of the large pottery works at Victoria has added to the decrease in production of structural materials, but this loss in output is only temporary, the erection and equipment of new works having been provided for.

The following table shows the mileage of the various classes of work carried out under Street Improvement By-laws and General Revenue for 1913 at Vancouver, B.C.:—

	Miles.
Clearing and rough-grading streets	22.134
Ditching and crowning streets	4.516
Clearing and rough-grading boulevards	17.822
Clearing and rough-grading lanes	5.250
Grading streets	12.688
Grading boulevards	15.155
Grading lanes	3.000
Rocking streets	5.148
Rocking lanes	2.110
Extending rocking to curbs	1.228
Resurfacing streets	4.405
Plank roadways, streets	22.941
Plank roadways, lanes	12.107
Three plank walks	32.460
Bulkheads	.825
Culverts and box-drains	.664

Coast to Coast

Moose Jaw, Sask.—The City Council of Moose Jaw has voted down the recommendation of the city commissioners that drilling for gas at the city test well be discontinued.

Moose Jaw, Sask.—The new ten-circuit automatic storage battery switchboard, which will be installed at the Central Fire Hall, Moose Jaw, during the next month, will represent an outlay of $6,000.

Toronto, Ont.—The first through train has traversed the new C.N.R. line between Quebec and Toronto, arriving in Toronto on May 1; and the entire road has been pronounced satisfactory by the officials.

Winnipeg, Man.—Recently at Winnipeg a statement was published to the effect that the earnings on all Canadian railways during 1913 amounted, broadly, to $200,000,000 according to figures just compiled. These figures include all the subsidiary lines, and other affiliations of any nature.

Port Mann, B.C.—Plans are being perfected by the C.N.R. for extensive terminal facilities at Port Mann, B.C., its Pacific freight terminus and ocean port. Plans passed upon this year by the management call for yard trackage to store and manipulate 10,000 freight cars and 1,000 passenger coaches.

Vancouver, B.C.—The Burrard street bridge, a part of the C.P.R. terminal improvement scheme at Vancouver, has been completed with the exception of the ramp, which will lead from the waterfront end of the viaduct to the dock level; and this cannot be built until the old immigration sheds have been removed

Bassano, Alta.—The great irrigation dam of the C.P.R. at Bassano, Alta., was formally opened on April 26 by Sir Thomas Shaughnessy, president of the company. It is claimed that the Bassano dam is the largest in the world, and is even longer than the famous Assouan dam of Egypt. The water it contains will cover 14,000 acres to a depth of one foot.

Toronto, Ont.—Owing to changes which have been effected in the Power Commission Act by the Ontario Legislature, Ontario townships will now be able to make contracts for hydro-electric power without submitting the matter to a vote of the ratepayers. All that is required is a petition from residents of the township; and when this is submitted and considered, the council may enter into a contract with the commission.

Guelph, Ont.—The annual report of the Light and Heat Commission of Guelph shows very satisfactory returns; and though the rates were reduced 5 per cent. at the beginning of the year for power, residential and commercial lighting, with the increase of business that this reduction has effected, it is expected to make a further decrease in rates at the end of the year or earlier. The report shows that over twice as many electric services were installed in 1913 than in the previous year.

Regina, Sask.—During 1914, over $1,500,000 will be expended on roads and road improvement in Saskatchewan, according to the decision of the highways commission of the provincial government. Of this outlay, $500,000 is to be expended in bridge work, the largest undertaking of the bridge department this year probably being the completion of the high-level bridge at Saskatoon, which is to be completed by December 31. Approximately $100,000 is to be expended on small concrete and steel bridges.

Toronto, Ont.—Main estimates have been tabled in the Ontario Legislature for 1914-15 totalling $9,810,749.66, while those tabled for 1913-14 were $9,524,387. Of this year's amount $8,811,749.66 is to be voted to meet current expenditure, while $849,000 will be set aside for capital expenditures, $150,000 being provided for other purposes. The current expenditures for 1913-14 were nearly half a million lower than for this session, being $8,353,387; but the amount provided for capital expenditure a year ago was considerably larger than the vote now asked for, running up to $1,042,000.

Montreal, Que.—The construction program of the Montreal harbor commissioners has been resumed. Dredging has been started on the South Shore Channel, and an endeavor will be made to have the channel completed before the closing of navigation. Also a start has been made at tearing down the old Victoria pier, work is being carried out at the new drydock, the widening of the ship channel in the harbor is to be continued, the construction of sheds at sections 23 and 24 is being rushed, while the addition to the commissioners' elevator is practically completed.

Saskatoon, Sask.—The total contract for the completion of the students' residence of the University of Saskatchewan, for which contracts were awarded last week, will entail an approximate expenditure of $216,000 for Section A; and, including Sections B and C, the total cost will be $265,000. In addition to the residence construction, the new Physics Laboratory will be constructed this year at a cost of between $120,000 and $150,000, and will constitute the first unit of the new science block. Also this year the foundation work for the proposed chemistry building will be undertaken.

Vancouver, B.C.—According to the opinion of Engineer Breckon of Vancouver, the laying of pipe across the First Narrows, including the hauling of the second main already started, will entail an additional expense of $6,000 to $10,000, or about $70,000 for the rest of the work on the connecting of the Point Grey pipe with Little Mountain reservoir. Of this, $45,000 will be needed for the crossing of False Creek and the few special valves along the route for fire protection. At the end of March the expenditure on the pipe line was $430,738, so that the total cost will be more than $500,000.

Edmonton, Alta.—It has been reported at Edmonton that $500,000 has been received by the Provincial government of Alberta to be used for the building of western Canadian railway lines. It is stated by the secretary of railways that it is for the Canadian Northern Western, a subsidiary company of the Canadian Northern. This amount is the first instalment of $6,000,000, for which bonds were placed on the market last spring. Moreover, according to the railways branch, over $11,000,000 is available for railway construction in Alberta this year, on railways guaranteed by the Provincial Government; and it is estimated that 700 miles of railway should be constructed during the present year.

Toronto, Ont.—The C.P.R. bridge over the Don River, 9 miles from the Union Station, has been completed by the Walkerville Bridge Company. The contractors for the cement work were Dickenson and Burns. The new bridge is much stronger and heavier than the old bridge, alongside of which it has been erected. It is about 1,000 feet long, weighs over 1,200 tons, is 120 feet above the level of the River Don, and is supported by 9 steel towers and 2 concrete abutments. Two of the towers provide openings for roadways, one on either side of the river; while the largest tower spans the C.N.R. line to Winnipeg, 80 feet below the level of the bridge. The completion of the bridge allows now of the completion of the small portion of work yet undone on double-tracking the line from Agincourt to Leaside. When the other new bridge over the west Don has been finished, the two old bridges over the main and west Don rivers will be strengthened and improved so as to afford a complete double track from Streetsville in the west to Agincourt in the east.

Ottawa, Ont.—It has been announced recently at Ottawa that, with a view to enabling the engineers of the government to work [illegible] scheme of power development on the main Saskatchewan river, and at the same time not to impair future navigation, it has been considered advisable to have a thorough examination made on the ground by the hydraulic engineer of the water power branch this coming summer. In the meantime, Hon. W. J. Roche, minister of the interior, has directed that all available Dominion lands, contiguous to this power site, be removed from any disposition whatever, and be dealt with only under the Dominion water-power regulations. During the past two seasons the engineers of the Dominion water power department have investigated the possibilities of this river in the vicinity of Grand Rapids, where the river disgorges into Lake Manitoba; and, while incomplete, a photographic survey of the whole region has been made.

Fort William, Ont.—The mayor of Fort William has outlined to the city council an agreement which will doubtless be entered into by the city and C.P.R. company. It is to the effect that the city and the railway company shall jointly build a new subway with cement piers and abutments and steel superstructure at McVicar street, with a revetment wall that would give an additional width of 7 feet of roadway from the subways to the local sheds, and afford a double roadway and two sidewalks through the subway; that the city dock shall be extended 50 feet to the harbor line; that the company shall give the city 200 feet of frontage down the river from the present city dock; that the city shall give the company surface rights on McTavish street between the railway tracks and the river, reserving the right for an overhead right-of-way for access to a bridge, whenever it should be necessary; and that the city shall pave and maintain the Syndicate avenue subway. This basis of agreement has been authorized by council and forwarded to the company.

Toronto, Ont.—Recently in the Ontario Legislature, while outlining the expenditures for which a vote of $5,000,000 in the supplementary estimates has been required by the Hydro-Electric Commission, the Hon. Adam Beck stated that the question of the commission entering upon the work of actually producing power would sooner or later have to be solved. The Ontario Power Company is now supplying power to the Commission, and wants to have the contract reopened. It desires permission to utilize the remainder of the available water at Niagara Falls, which would bring its maximum development to 106,000 horse-power. If this is done it proposes to relinquish rights to export 50 per cent. of the power developed to the United States, and to leave 60 per cent. for use by the Hydro-Electric at $12 per h.p. The Commission is paying $9 per h.p. at present, and it is not thought that the $12 rate is low enough. If cheaper power cannot be procured the Commission may have to install its own plants. Two sites are available, one below the whirlpool, and the other the spillway of the Welland Canal, if power rights to this can be secured from the Dominion Government.

Esquimalt, B.C.—The following particulars have been published concerning the drydock to be constructed by the Dominion Government at Esquimalt. The north side of Lang's Cove has been chosen as the dock's site. Its dimensions will be as follows: length from caisson stop to head wall, 1,150 feet; width of entrance, 120 feet; depth on sill at ordinary high water spring tides, 40 feet; width at coping of dock walls, 144 feet. It will be divided, as stated, into two parts of 650 and 500 feet, respectively, each part being closed by a ship steel caisson. The dock will be emptied by [illegible] centrifugal pumps, each having a capacity of 60,000 [illegible] per minute. The pumps and other machinery will be run by electric power generated by the dock power plant. After the rock excavation has been finished, the walls will be constructed. For these concrete will be used, with granite copings and alters. All keel and bilge blocks will rest on granite stripe extending the full length of the dock, and granite will be used for caisson stops. On the south side a basin will be formed; and the structure around this will be built of reinforced concrete piles. In addition to the drydock work proper, a large area of land must be reclaimed, and an extensive frontage of wharves, for which reinforced concrete will be used, must be constructed.

Medicine Hat, Alta.—Contracts have just been awarded by the Southern Alberta Land Company, of Medicine Hat, for the removal of some 560,000 cubic yards of earth, for the purpose of carrying to completion the first stages of the work and the placing of about 30,000 acres of land under water by next spring. All contracts are to be completed by October 15, 1914, and the total cost will be about $80,000, running somewhat under the engineers' estimates. In about two weeks another contract will be let for 150,000 more cubic yards of excavation, part being at the Little Bow river and the balance near the head of the main canal near Gleichen. The contracts let this week are for some 5 miles of the main ditch, leading from the new reservoir to the Little Bow river, which is some 15 miles from the main reservoir, known as Lake McGregor—this main canal to be 44 feet wide at the bottom, 78 feet across the top, and to hold 8 feet of water; and for the laterals, to provide for the direct watering of the 30,000 acres of land next spring. On April 1st occurred the completion of the new dam at the intake on the Little Bow river, a piece of work that represents a cost of about $70,000. By July 1st or sooner, water will be turned into the main canal, the reservoir holding about 30,000 feet of water. Thus far the company has expended about $4,500,000 on this enterprise, and it bids fair to be one of the most important in the Canadian West, as the plans call for the irrigation of over 200,000 acres of land.

Victoria, B.C.—Active operations are reported as now in progress by the contracting firm, Messrs. Grant, Smith, and McDonnell, in connection with the building of the two new piers in the greater harbor improvement program. Five large scows have arrived at Vancouver for the purpose of dumping the rubble foundation of 300,000 tons, of which the first 60,000 tons is ready for delivery. The cribs to be built will be 58 in number. Each requires 110 tons of steel work, and when complete will be a ferro-concrete structure weighing 3,500 tons. These will be constructed on a floating drydock which is now at the Bremerton Navy Yard, in Seattle, and which will arrive at Victoria shortly. This drydock has a carrying capacity of 8,000 tons, is 385 feet long, 115 feet wide, and has a depth of 55 feet. When the drydock has been delivered, the construction of cribs will commence at the company's gravel property at Albert Head, where excavations are to be made to provide a slip for the floating dock. The most modern machinery for the removal of the gravel will be installed at a cost of $40,000; and when in operation, the output will be in the neighborhood of 1,800 cubic yards daily. Also, the company proposes opening up and equipping with donkey engines, steam shovels, etc., a rock quarry in the vicinity of Victoria, by means of which the company expects to bring to the site of the piers about 60,000 tons of rubble each month. It is anticipated that the necessary quantity of material will be dumped before next winter is far advanced. When the work is well under way, the contractors will have 12 scows, a dredge scow and a drill boat in operation, the latter to be used in removing rock for excavating underneath the cribs. The contract is to be carried out under the supervision of Mr. J. S. Maclachlan, Dominion Resident Engineer.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page 90, a directory of such societies and their chief officials.

AMERICAN SOCIETY C.E. CODE OF ETHICS.

The Board of Directors of the American Society of Civil Engineers is placing before the membership the following proposed code of ethics, and is recommending its adoption:—

It shall be considered unprofessional and inconsistent with honorable and dignified bearing for any member of the American Society of Civil Engineers:—

(1) To act for his clients in professional matters otherwise than as a faithful agent or trustee, or to accept any remuneration other than his stated charges for services rendered his clients.

(2) To attempt to injure falsely or maliciously, directly or indirectly, the professional reputation, prospects, or business, of another Engineer.

(3) To attempt to supplant another Engineer after definite steps have been taken toward his employment.

(4) To compete with another Engineer for employment on the basis of professional charges, by reducing his usual charges, and in this manner attempting to underbid after being informed of the charges named by another.

(5) To review the work of another Engineer for the same client, except with the knowledge or consent of such Engineer, or unless the connection of such Engineer with the work has been terminated.

(6) To advertise in self-laudatory language, or in any other manner derogatory to the dignity of the profession.

It is noteworthy of observation that the American Society of Mechanical Engineers and the American Institute of Electrical Engineers have both discussed codes that are very similar to each other, the latter having already adopted theirs. The above code, compared with the others, is quite brief and simple, and free of all attempts to lay down general rules of practice that are devoid of ethical bearing.

The draft will be presented to be acted upon by the members at the convention in Baltimore, Md., on June 2nd. The opinion generally expressed is that it will be adopted.

CLUB "SMOKER."

The Engineers' Club of Toronto will hold a smoker in the club rooms on Friday evening, May 8th. The occasion will admit of examination and criticism of the preliminary plans of the proposed new Engineers' Club building.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Diven, 47 State Street, Troy, N.Y.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—**To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.**

INTERNATIONAL CONFERENCE ON CITY PLANNING to be held in Toronto, May 25-6-7, 1914, in charge of the Commission of Conservation. Secretary, James White, Ottawa.

AMERICAN SOCIETY FOR TESTING MATERIALS. **—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.**

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Summer convention to be held at Brighton Beach, N.Y., July 3rd and 4th, 1914. Secretary, J. R. Wemlinger, 11 Broadway, New York.

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal.

AMERICAN PEAT SOCIETY.—**Eighth Annual Meeting will be held in Duluth, Minn., on August 20, 21 and 22, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.**

CANADIAN FORESTRY ASSOCIATION.—**Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.**

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—**Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal.**

CONVENTION OF THE AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—To be held in Boston, Mass., on October 6th, 7th, 8th and 9th, 1914. C. C. Brown, Indianapolis, Ind., Secretary.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9-13, 1914. J. E. Pennybacker, Secretary, Colorado Building, Washington, D.C.

PERSONALS.

G. W. BARRETT was recently appointed sewerage engineer for the town of Esquimalt, B.C.

NORMAN HICKS has been appointed engineer to the town of Weston, Ont., and to the Weston Water, Power and Light Company.

G. H. ARCHIBALD, of St. Catharines, has been appointed city engineer of Saskatoon, Sask., to succeed Geo. T. Clark, resigned.

J. L. BUSFIELD, B.Sc., of the Mount Royal Tunnel and Terminal Company, Montreal, has recently been elected associate member of the Institution of Civil Engineers, Great Britain.

C. C. MENDHAM, who has been connected with the outdoor staff in Toronto of the Herbert Morris Crane and Hoist Company, Limited, has now been appointed resident engineer in Berlin for that company.

OBITUARY.

The death occurred at Beamsville, Ont., on May 4th of Senator William Gibson, who for many years took an active part in railway and bridge building in this country. For 22 years he had charge of the construction of masonry work on the Grand Trunk system in Canada. He built the approaches and portals of the Sarnia tunnel and had charge of the doubling of the Victoria Jubilee bridge at Montreal.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21666—April 17—Authorizing C.P.R. to construct spur for J. E. Wilder, Montreal, Que., from point on easterly limit of right-of-way of main line, Farnham Subdivision, in Lot Cadastral No. 70-A, (Civic), Cote des Neiges Ward, city of Montreal.

21667—April 17—Authorizing C.P.R. to construct spur for Goold, Shapley and Muir Co., Limited, Regina, Sask.

21668—April 17—Authorizing C.P.R. to construct, at grade, tracks of spur for city of Moose Jaw across River St., in said city; and to construct, at grade, 2 tracks of wye connection on Main line, Sask. Div., across Manitoba St., and Second Ave., city of Moose Jaw, Sask.

21669—April 15—Authorizing C.P.R. to construct spur for city of Edmonton, Alta.

21670—April 16—Authorizing C.P.R. to reconstruct bridge No. 37.5 on Havelock Subdivision, Ontario.

21671—April 15—Authorizing Esquimalt and Nanaimo Ry. to construct siding for Empire Lumber Co., from a point on Osborne Bay Branch of its Railway, mileage 2.5, Vancouver Island, B.C.

21672—April 18—Approving location Pointe aux Tremble Ry. through town of Montreal East, Que.

21673—April 18—Authorizing Cedars Rapids Mfg. and Power Co. of Montreal to take an additional width for its right-of-way for its transmission line across certain lots in Parishes of St. Joseph de Soulanges and St. Ignace du Coteau du Lac, Province of Quebec.

21674—April 17—Directing that C.P.R. construct spur from point on its railway connecting main line with St. Lawrence and Ottawa Line, leading to Sussex St. freight yards, to and into premises of Dustbane Manufacturing Co., Limited, Tp. of Gloucester, Co. Carleton, Ont. subject to and upon certain conditions.

21675—April 18—Authorizing C.P.R. to construct a rearrangement of sidings for McGregor and McIntyre, Limited, on parcel of land lying north of its tracks and easterly of Shaw Street, North Toronto, Ont.

21676—April 18—Authorizing C.P.R. to construct spur for S. A. Early and Company, Limited, in Subdivision, Lot 26, Block 165, city of Saskatoon, Sask., on Co.'s main line, Sask. Division.

21677—April 18—Authorizing C.N.O.R. to construct across Scarlett Road, between Lots 36 and 37, Cons. 3, F.B., Tp. York, Ont., by means of a structure carrying highway over railway.

21678—April 18—Authorizing C.N.O.R. to construct across Jane St., between Lots 36 and 37, Con. 3, F. B., Tp. York, Ont., by means of structure carrying highway over railway.

21679—April 20—Directing that C.P.R. construct spur into premises of S. A. Hamilton Co., Limited, crossing First Ave West in city of Moose Jaw, Sask., subject to and upon certain conditions.

21680—April 18—Authorizing C.N.R. to construct across twenty-nine (29) highways in Province of Saskatchewan.

21681—April 21—Relieving G.T.R. from providing further protection at crossing of highway immediately east of Pike Creek Flag Station, Tecumseh, Ontario.

21682—April 22—Authorizing G.T.P. Branch Lines Co. and C.P.R. to operate trains over crossing by G.T.P. Branch Lines Co.'s tracks of C.P.R. Calgary to Edmonton Branch, in City of Calgary, Alta., without being brought to a stop.

21683—April 21—Amending Order No. 18032, dated Nov. [illegible] by adding after word "Company" in [illegible] line of operative part of Order, words "[illegible] such cost, [illegible] borne and paid by Village of [illegible]."

21684—April 21—Relieving G.T.R. from providing further protection at crossing of Colborne St., City of London, Ont.

21685—April 20—Authorizing, subject to terms and conditions contained in agreement, C.P.R. to construct highway crossing, at level, over its tracks, at McDougall St., in City of Port Arthur, Ont.

21686—April 22—Suspending "sine die," schedules of G.T.R. and M.C.R.R. in so far as they increase rates now charged on Caustic Soda and Bleaching Powder; disallowing schedule of P.M.R.R. in so far as it increases rates heretofore charged on Caustic Soda and Bleaching Powder; and directing that rates lawfully in force on said commodities immediately prior to effective dates of said schedules be continued in effect until further Order of Board.

21687—April 22—Authorizing, at its own expense, Board of Highway Commissioners for Prov. Sask., to construct highway crossing through station grounds of C.N.R. at Brancepeth siding, N.W. ¼ Sec. 27-46-23, W. 2 M., Saskatchewan.

21688—April 21—Authorizing C.N.R. to construct Seventeen (17) highways in Province of Alberta.

21689—April 25—Amending Order No. 20423, dated Sept. 25th, 1913, by inserting certain words and figures and adding certain clauses.

21690—April 27—Amending Order No. 21513, dated Mar. 16th, 1914, by striking out words, "the cost to be divided equally between the two companies," in 6th and 7th lines of operative part of Order, and substituting words, "the cost to be borne and paid by the Applicant Company."

21691—April 26—Authorizing C.L.O. and W. Ry. (C.P.R.) to take certain lands in town of Bowmanville, Co. Durham, Ont., for purpose of constructing a freight yard, and approaches thereto, subject to and upon certain conditions.

21692—April 23—Authorizing Cedars Rapids Mfg. and Power Co. of Montreal, to take additional width of 25 ft. for right-of-way of its transmission line across Lot 7, Con. 2, Tp. Cornwall, Co. Stormont, Ont., property of James Dingwall.

21693—April 28—Amending Order No. 21476, dated March 11th, 1914, by striking out words, "the bridge over," in recital of Order, and words, "bridge over the said," in operative part of Order.

21694—April 21—Relieving C.P.R. from speed limitation of fifteen miles an hour over railway between mileage 0 and 41, Golden to Spillimacheen, B.C.

21695—April 28—Authorizing C.P.R. to operate over Two bridges, namely, No. 15.6, Alta. Div., Lethbridge Sub. Div., and No. 91.1, Alta. Div., Lethbridge Sub division, Alta.

21696—April 27—Dismission complaint of Milton Pressed Brick Co., Ltd., of Milton, Ont., against action of C.P.R., in holding up construction work on their double tracking between Toronto and Guelph Jct., Ontario.

21697—April 28—Authorizing Kettle Valley Ry., to construct ,at grade, its ballast pit spur across highway between

21698—April 29—Authorizing C.N.R. to construct spur for P. O. Dwyer Co. across Elm Ave., through Blocks 112 and 113, Parkdale, Edmonton, Alberta.

21699—April 29—Authorizing G.T.R. to construct certain extensions to branch line, or siding, and spur therefrom, into premises of Maple Sand, Gravel and Brick Co., Ltd., Tp. Vaughan, Co. York, Ontario.

21700—April 29—Authorizing G.T.R. to construct siding into premises of Toronto Brick Co., Ltd., Tp. Scarboro, Co. York, Ont., near York Station.

21701—April 29—Authorizing Alberta Central Ry. to construct, at grade, its ballast pit spur across highway between N.E. ¼ Sec. 8 and N.W. ¼ Sec. 9-39-3, W. 5 M., and highway between N.E. ¼ of Sec. 8 and S.E. ¼ Sec. 17-39-3, W. 5 M., Alta., at mileage 34 west of Red Deer.

NOTABLE RAILWAY CROSSING IN NEW BRUNSWICK

SAINT JOHN & QUEBEC RAILWAY CROSSING OVER THE CANADIAN PACIFIC RAILWAY—INTERESTING RETAINING WALL WITH COUNTERFORTS—GENERAL NOTES ON CONSTRUCTION.

By S. B. WASS, A.M. Can. Soc. C.E.
Chief Engineer, Saint John and Quebec Railway.

IN the location of the Saint John & Quebec Ry. it was necessary to cross the Canadian Pacific Ry. branch from McAdam Junction to Woodstock, N.B., in the vicinity of Woodstock. The latter railway runs along a slope parallel to the River St. John at about the grade base of rail of the Saint John & Quebec Ry. was required, and a through plate girder with the floor beams and stringers set on the bottom flange of the main girders was used. After a study of the conditions, the ground plan shown in Fig. 1 was adopted as that most suitable.

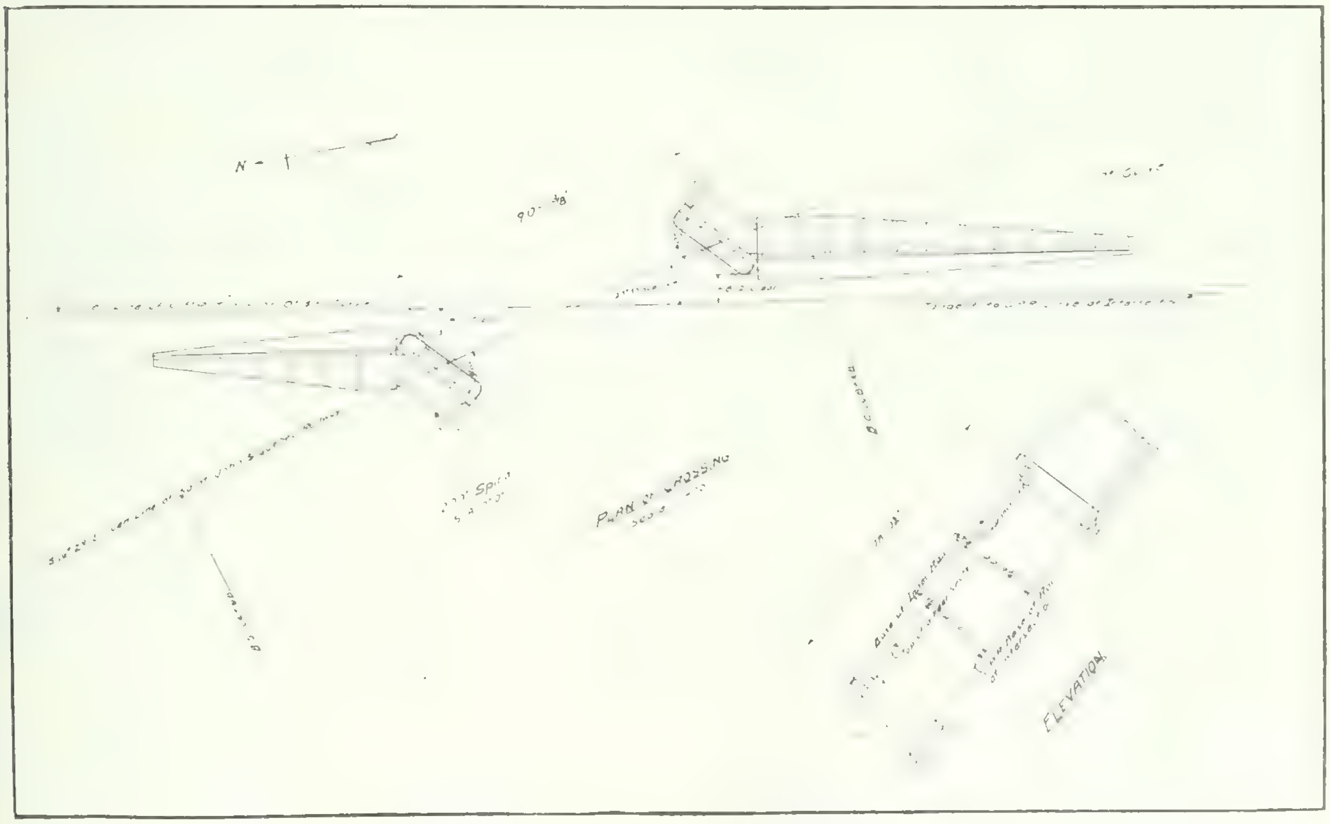

Fig. 1.—General Plan and Elevation of Crossing, Showing Alignment of Tracks.

of the natural ground. As there was no large cutting or embankment convenient for use, it was necessary to construct an embankment on the lower side of the Canadian Pacific Ry. tracks, for the support of the new road. To keep this as small as possible, the angle of crossing between the two roads was made very acute. That the grade of the embankment be kept as low as possible, the minimum distance between the bottom of the steel and the

In making these calculations the standard plans of abutments and gravity wing walls were used.

The design of the masonry for this structure was quite important and more especially the wing or retaining walls, one on each side of the Canadian Pacific Railway.

Design of Wing Retaining Walls.—As experience rather than theory is the necessary guide in building walls, and although theory would lead us to build a much thinner

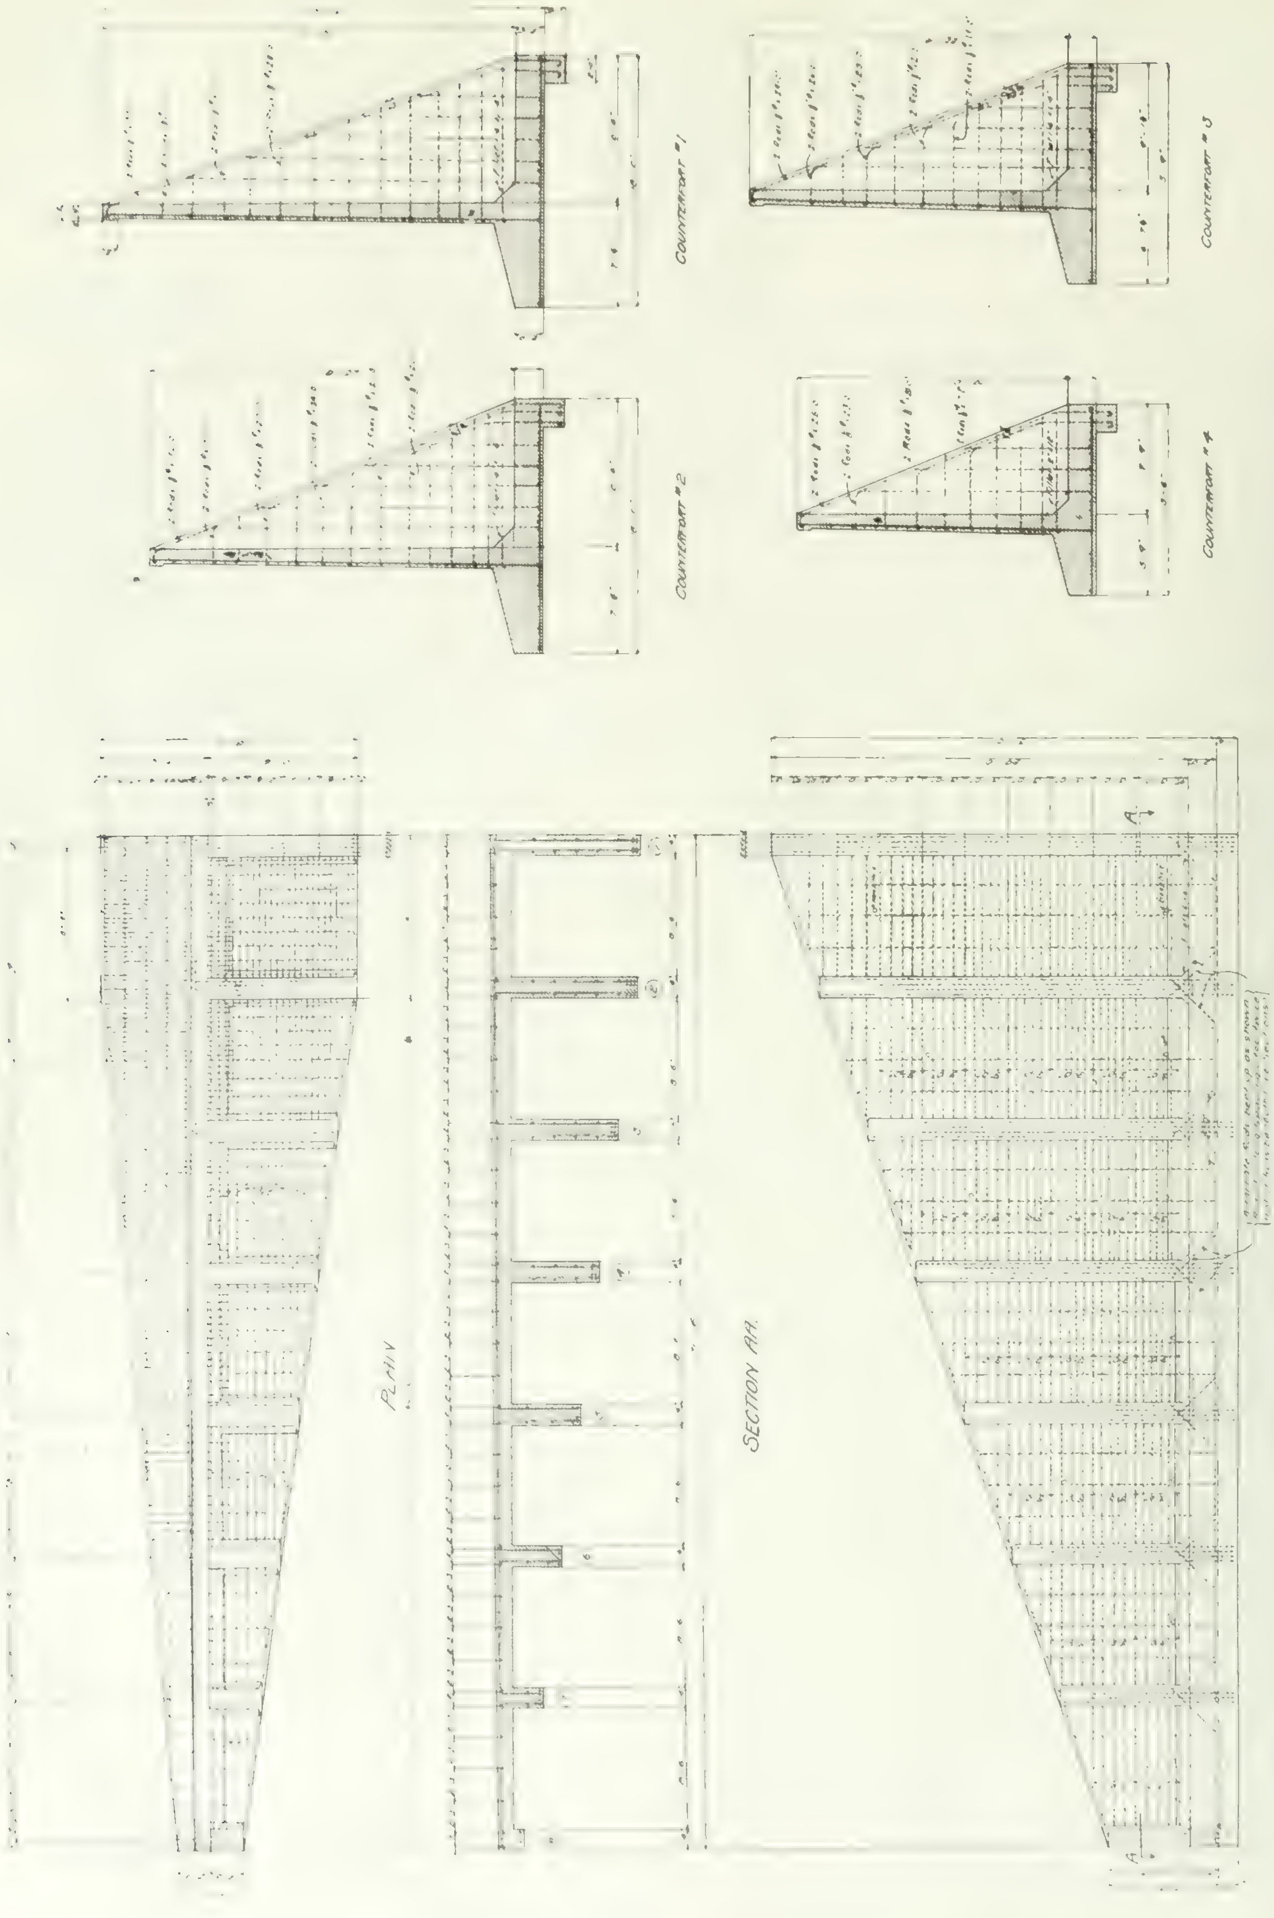

Fig. 2.—Details of the north wall, showing plan, elevation and sections of four of the eight counterforts.

wall, it is the practice of engineers to make the width of the base of a retaining wall 0.35 to 0.45 of the height, and in some cases where there is an additional load due to surcharge of earth, street or railway traffic, walls have been built with bases as wide as 0.5 of their height.

In the case under consideration the foundation was of stiff grayish-brown clay or hard pan, with some boulders and small stones mixed among it and which could be well drained, so was considered sufficiently good support. The embankment which the wall was to retain would be made of train fill material hauled on cars from the ballast pit and dumped from a temporary trestle. As will be seen by reference to Fig. 1, the upper portion of the wall would extend to the elevation of base of rail and would be subjected to the live load on the track in addition to the embankment. From this point to the lower end of the wall the embankment lies at natural slope to elevation of grade. It was, therefore, assumed that the whole wall had a surcharged load and that a gravity wall should have a thickness at its base of 0.45 feet of its height. A wall 1.5 feet thick on top and increasing one foot in thickness for each 2.25 feet in height will give the required base. It became evident for several reasons that a reinforced concrete wall would be better suited to the conditions than a gravity wall:

(1) The unit pressure on the foundation at the toe of the wall would be reduced by the use of a wider base, which could be easily accomplished in the reinforced wall, which was actually made 18.0 feet wide for the highest part of the wall, while that for the gravity wall is 13.63 feet.

(2) The vibration due to the traffic on the C.P.R. track, which lies within eight or ten feet of the wall, would be better resisted by a reinforced structure than by one of plain concrete.

(3) The cost of the structure could be reduced.

Reinforced concrete retaining walls divide themselves into two types, viz., "inverted T" and "counterfort wall." The inverted T type has the advantage of being of much simpler shape and so requiring less form work than the other. Under ordinary conditions of foundation, cost of materials and labor, it is found to be economical up to a height of about 20 feet. The counterfort wall type was chosen on account of the closeness to the C.P.R. tracks, where traffic must not be interrupted. This fact made it necessary to have as much of the base as possible back of the face of the wall. Fig. 2 shows an elevation and sections of the north wall as designed and constructed. The horizontal earth pressure against the face of the wall between the counterforts is transmitted to them by the thin wall slab. Each counterfort was designed to resist the entire over-turning moment and bending moment produced by the resultant horizontal pressure of the earth. The portion of the base back of the wall was designed as a slab, carrying the weight of the earth above it and supported by the counterforts, and the portion in front as a cantilever fixed at the face of the wall and reinforced to resist the reaction of the ground. The tendency to slide is overcome by the sides of the excavation, which were cut to neat size of the base and the concrete poured up against the natural ground without any form. Additional safeguard against sliding was provided by making a projection on the bottom of the base at the back two feet wide and one and one-half feet deep. In this case no two counterforts were the same height in the same wall, which necessitated a separate design for each one. To prevent making the form work too expensive the space between the walls was increased from seven or eight feet (as is usually the case) to ten feet, with a corresponding increase in thickness of walls. The counterforts are 1.5 feet thick throughout. The same slope was used on the back of each one, so that the forms could be used on a counterfort of the same height, or on a shorter one by simply cutting it off at the bottom on the second wall. The wall is one foot thick on top with a coping two inches

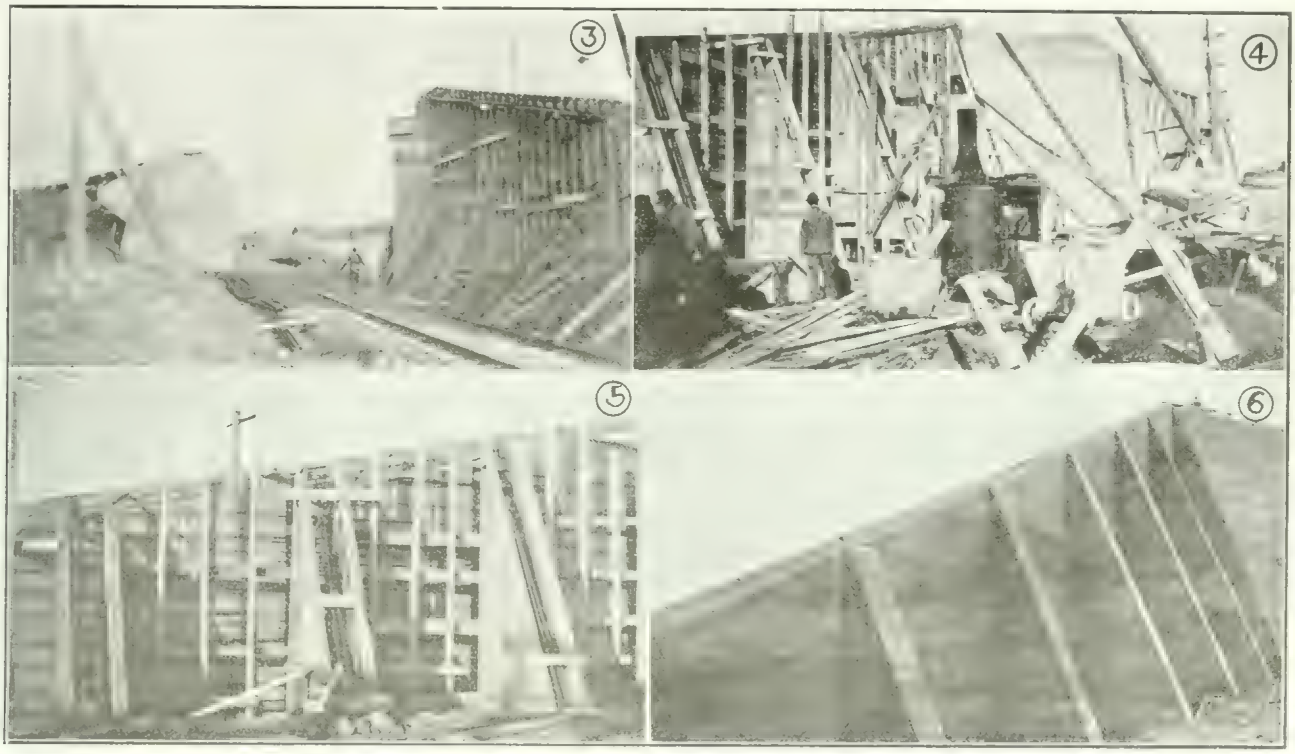

Fig. 3.—Abutments in place on either side of the C.P.R. line. Figs. 4 and 5.—Formwork and reinforcing of wall ready for concrete. Fig. 6.—Completed wall from counterfort side.

thick and one foot deep on the outside. The face of the wall has a batter of one-quarter of an inch to the foot and the back is plumb.

Three-quarter inch round rods of mild steel were used throughout with the exception of the backs of the counterforts where the tension strain to resist overturning was so great that it was considered best to use one and one-eighth inch round rods. The increased reinforcement required in the front of the wall, due to increased height, was taken care of by spacing the horizontal rods closer. The rods for the back of the counterforts were delivered from the rolling mills, cut the required length, while the three-quarter inch rods for the wall were delivered in thirty-two-foot lengths, which is the length of two spans with two feet for lap at the splice. This length is as long as could be conveniently loaded on cars. Care was taken that the joints in the adjacent rods did not come at one counterfort, this being accomplished to a large extent automatically by commencing each horizontal rod at the outer end of the wall. Splices in horizontal rods were made by giving a two-foot lap in all cases over a counterfort. Wherever possible, the end of all rods were hooked over a rod running at right angles to it.

After the excavation had been made for the foundation a layer of concrete about three inches thick was placed in the bottom to form a hard, uniform floor for the men to work on and to protect the clay from becoming worked up if the weather should be wet. It was not possible to erect any staging to do any work from the front of the wall on account of the closeness of the C.P.R., as is seen from Fig. 3. The form for the face was put in place and boarded to the top, the studding being allowed to extend to the three-inch base, which had been put in. The frames of the forms for the back and counterforts were put in place with just enough boarding to brace them strongly, these studs also being allowed to extend to the base. The ends of the studs may be bored out and the holes filled with concrete. On this frame was suspended the reinforcing steel, which was securely held in its proper position by wires and blocking. Figs. 4 and 5 show the reinforcing in place before concrete was put in. The concrete was mixed quite wet and dumped from a large bucket into chutes placed at short intervals along the wall. The boarding-up of the back of the wall and of the counterforts was kept only a short distance above the concrete so that an opportunity would be given the men to tamp the concrete. The carpenters and the tampers used the same staging and very little difficulty was experienced in getting the material well tamped and to present a smooth surface. The gravel used for the concrete was taken from a bar in the St. John River, was clean and sharp and consisted of quartz and granite stones and sand so mixed that it was not considered necessary to screen it or to add any other material. The concrete was composed of six parts of this gravel to one of cement. The wing wall was separated from the abutment by a vertical joint. It was not considered necessary to provide any other expansion joint in this length of wall. Fig. 6 shows a view of the back of the finished wall.

In the north or smaller wall there is 172.8 cu. yd. of concrete, 14,300 lbs. of steel rods, while the gravity walls would have required 324 cu. yd. of concrete. In the long or south wall there is 235.8 cu. yd. of concrete and 23,300 lbs. of steel rods, while in the gravity wall there would have been 478 cu. yd. of concrete. The actual cost of two walls was $6,817, and was constructed by contract for 82.5 per cent. of the cost of a gravity wall. The price paid per yard for reinforced concrete was about one dollar more than it should have been to be consistent with the price per yard of plain concrete. If the prices had been consistent the reinforced wall would have been constructed for 78 per cent. of the gravity wall.

Design of Abutments.—The abutments are of peculiar shape but do not present any particular difficulty, the general appearance of which may be seen in Figs. 3 and 7. They are of monolithic design, except for a small lug or wing on the side opposite to the large wing wall. The abutment is allowed to be partially submerged on side of the structure so little or no advantage could be gained by reinforcement.

Fig. 7.—Showing Special Type of Abutment.

Fig. 8.—Erection of Steel Girders.

Fig. 8 shows the steel girders being placed in position by the derrick car of the Dominion Bridge Company.

The design and drawings were made by Mr. W. G. Bullock, bridge engineer for the railway company. The construction was in charge of Mr. B. M. Hill, division engineer, and Mr. F. W. C. Wetmore, resident engineer. The concrete work was done under contract by Mr. W. H. A. Hamilton, Mr. E. S. Haines, superintendent, and steel superstructure by the Dominion Bridge Company, to all of whom credit is due for the careful and energetic manner in which the work was carried out.

PROPOSED EDMONTON BRANCH, CAN. SOC. C.E.

An application to establish in Edmonton a branch of the Canadian Society of Civil Engineers has, according to report, been granted. On May 1st a meeting was held by the resident members of the Society to discuss the organization of the proposed branch.

DESIGN OF STEEL AND REINFORCED CONCRETE PILLARS.

In a paper read recently before The Concrete Institute of Great Britain, Mr. Oscar Faber, B.Sc., dealt with the above subject, making special reference to secondary and accidental stresses. He divided his paper into two sections, first taking up jointed construction such as structural steel and afterwards monolithic construction, such as reinforced concrete. He examined the case of a girder resting on the end of a steel stanchion and stated that in several drawing offices he knew as a fact that the construction in such a case would be treated as centrally loaded. He proceeded to argue that such was not the case because, when a load was applied to the beam it would deflect and the end originally horizontal would assume a certain slope and therefore one of two things would happen, namely, (*a*) the end of the girder would lift, in which case the whole load would be carried on one flange, so causing eccentric loading; or, (*b*) the column must be constrained to adapt itself to the slope of the girder, in which case a bending moment would be introduced into the stanchion by such constraint. In this way he showed that increases in strains of 140 and 480 per cent. respectively were obtainable.

Mr. Faber took secondly for consideration the case of a girder resting on an angle bracket. He argued that if an ordinary bracket were used the action would not be very far from the face of the leg of the angle since the horizontal leg of the angle would not be strong enough to resist the bending moment which would be produced in it. It followed, therefore, that although the horizontal leg of the angle served a useful purpose in connecting the girder to the stanchion it must not be thought capable of supporting it. In effect the construction became dangerous if the clearing between the face of the stanchion and the edge of the girder exceeded the thickness of the angle. The author of the paper supposed there were few engineers who would assert that this limiting clearance was never exceeded in practice and an engineer had to carefully consider whether it was desirable to employ this type of bracket except for quite small reactions.

He next considered a stiffened bracket. Confining attention to cases where the workmanship was good, he assumed that the stiffening angles had been machined or forged to fit the angle bracket perfectly, and that the bracket was initially horizontal. It followed that, when the girder deflected there was a tendency for it to rest on the outer edge of the bracket, and for very small loads there was no doubt that this actually happened. As the load increased the outer edge of the stiffeners yielded appreciably, and a greater area supported the load, the reaction gradually approaching the face of the column. The author's practice was to make the web of the stiffeners sufficient in area to carry the reaction under a uniform stress of 7½ tons per sq. in.

In calculating the resistence, he ignored a large area of steel in the flange of the stiffeners, and in the vertical leg of the angle bracket because: (*a*) The clearance between the face of the stanchion and the end of the girder might be sufficient to prevent bearing on this steel; (*b*) even if it was not, this material could not be stressed appreciably until thé stiffener webs are greatly overstressed.

In any case, the difference in cost between good and bad brackets was an extremely small percentage of the cost of the steelwork, and a smaller one of the cost of the building, and he declined to endanger the "ship" for what, in this case, might be fairly described as a "ha'porth of tar."

It has long been recognized in good practice that the machining of the ends of stanchions was of the first importance. Yet, there were at least two constructional works in London which, with a view to economy, omitted this item of workmanship, and were erecting considerable tonnages of stanchions with the ends left so that the upper tier had contact with the lower tier over the width of one plate only, the remainder of the section having varying clearances often amounting to ⅛ in. The stress was still gaily calculated as uniformly distributed, and it had been explained to the author that "steel is a ductile material which would yield and flow" and perform other convenient antics, "until the stress was uniformly distributed." The effect of loading such a stanchion was to cause the plates to slide past one another, and to partly shear through the rivets. Even where stanchions are machined, a careful engineer must satisfy himself that they were machined truly square. Architects should bear in mind also that apart from the danger involved in these practices, the yielding of stanchions and brackets before they obtain their bearing involved unknown and unintended stresses on the stonework, and to the author's knowledge many a beautiful and costly facade and interior decorative work had been badly cracked by bad steelwork details and workmanship.

From the consideration of case 1, it would appear to follow that it was desirable to make these joints somewhat flexible, and occasionally this was so. If buildings were braced with diagonal braces, he should say without question, that stiffness of connections should be avoided. Unfortunately, such bracing had obvious objections, and the whole stiffness of practical buildings against wind laid in the stiffness between beams and stanchions. There was, therefore, no alternative but to make the joints stiff and to make the necessary allowance for these secondary stresses in the design of stanchions. This might be onerous, both in requiring extra labor and an increase in material, but a conscientious engineer would grudge neither the one nor the other.

Mr. Faber then dealt with the design of cleats. A common method of calculating the safe reaction of a cleat was to take it as the sum of the resistances of the rivets, the effect being to neglect the very appreciable stresses due to bending.

Dealing with the bracing of pillars, Mr. Faber said that it was well known that pillars failed by buckling and that their stress was to be determined with reference to their length. This phenomenon was fairly well understood and there are sufficient experimental data available to make the design of pillars, with reference to what he might call primary buckling, a comparatively simple matter. The phenomenon to which he referred was that of secondary buckling, in which the pillars, instead of buckling as a whole, fails by the individual buckling of its component members. On this subject there appeared to be practically no experimental data and practically no formulæ or rules for the guidance of a designer. The importance of this problem might be gathered from the fact that bad design in the matter of bracing in pillars was certainly responsible for the two greatest failures in recent years—the Quebec bridge of 1907 and the gasholder in Hamburg.

Mr. Faber then proceeded to the second portion of his paper, treating of monolithic construction and the eccentricity of beam reactions on pillars therein. Whereas in steel construction the eccentricity was very definite and

easily calculated with most common types of brackets, with reinforced concrete the eccentricity could only be calculated from considerations of elastic flexure, and the problem was a much more difficult one. There was, however, no longer any excuse for claiming ambiguity since the problem had been analysed very completely in "Reinforced Concrete Design" and numerical examples fully worked out. The author took as an example the case of the outside column of the building, working it out in detail, showing very great increases in stress over the values as ordinarily calculated. If thoughts of eccentricity were banished, either from ignorance or under stress of competition, the actual maximum stress would have been 1,300 lb. per sq. in. It is interesting to note that the outside pillar in good design did not suffer much reduction in size-up through the last three tiers. This was in accordance with the best practice in steel-frame buildings.

In conclusion, Mr. Faber said that without suggesting for a moment that the engineering staffs of several constructional firms were not fully as efficient as many consulting engineers, he did feel that the system of competitive designs and lump sum prices penalized good designing by such firms, and secured the work to those responsible for the most risky design. The only correct system, in his opinion, was for the architect to entrust the design to an engineer who had his confidence and to invite tenders on the design which he prepared. The architect and building owner were then likely to obtain a sound construction and if they used their discretion in the choice of the engineer the work would not cost more than the minimum consistent with safety.

The best constructional firms would be protected by being protected from competition with weak design and bad workmanship. In considering tenders, he held that an engineer should give preference to those firms whose detailing and workmanship he knew he could rely upon. He urged this in the interest of the building owner, knowing as he did the importance of good details and good workmanship.

OIL FROM CARBONACEOUS DEPOSITS.

Interesting data is gradually coming to light in regard to the employment of low temperature for distilling the various products from coal and other carbonaceous substances, and from these it appears that the distillation has been carried out more with the object of obtaining products other than oil. Since, however, oil has come to be one of the most important power producers attention has been directed to distilling carbonaceous substances with the sole purpose of obtaining oil therefrom, and there can be little doubt that this is a line of investigation and working which will occupy the most prominent place in the future.

Damage to the extent of $500,000 was done by fire which broke out on April 18 on the premises of the Alberta Lumber Company at Vancouver, B.C.

It has been announced at Pittsburg that a company has been organized to manufacture ferro-manganese from American ores, capitalized at $12,000,000, and to be located at Dunbar, Pa. Heretofore ferro-manganese has been imported from England and Germany, with the exception of small quantities manufactured by the largest interests for their own use.

The laying of telephone cables across St. John Harbor, N.B., is being planned and the New Brunswick Telephone Company has engineers busy selecting landing places for the cables. It is reported that tenders have been submitted by several companies for the supplying of the cables, and plans and specifications submitted. It is expected the work will be completed by July 1st. According to the engineers, [illegible] cables will be needed for the work.

PROGRESS ON THE SIMPLON TUNNEL.

It is probable that by the end of the year the Second Simplon tunnel, 12 miles 588 yards in length, will be half completed. It is the longest tunnel in the world and is being constructed in the Alps by the engineers of the Swiss federal railways to cope with the remarkable growth of tourist and goods traffic on the Simplon route. It runs parallel to the existing tunnel, and is being made by an enlargement of the parallel working gallery made by the engineers of the former tunnel. The cost is estimated at $6,925,000.

Apart from the use of explosives for blasting, compressed air is the sole power in use within the workings. The rock drills are operated by air, and the excavated material is drawn away by locomotives driven by air under a pressure of between 180 and 190 atmospheres.

One of the features of this new tunnel, according to a Swiss correspondent of The Engineer, is the adoption for the dry portions of the tunnel of a masonry lining of artificial stone instead of the natural stone hitherto employed in Alpine tunnelling. This artificial stone is composed of cement, limestone, and sandstone, and is being made at the Brigue end of the tunnel. The correspondent suggests that this new departure, which was strongly opposed at first, was influenced by the success with which composition stone and ordinary bricks have been used in England. The work of lining is stated to have been simplified by this new practice.

The nature of the rock at the northern end of the tunnel is stated to necessitate an immediate lining of the excavated portion, and timbering is being freely used to resist the immense pressure. No blasting is permitted during the passage of a train through the original Simplon tunnel, as the distance between the tunnel and the heading is only 26 feet. The risk involved upon the first tunnel is stated to have been estimated at $600,000.

The first Simplon tunnel, it may be remembered, was constructed by the Swiss firm of Brandt, Brandau, and extraordinary precautions were taken for protecting the health and lives of the workmen. The precautions, however, were justified by the results, and a singularly difficult piece of engineering was carried through with a marked absence of illness. The necessity for a parallel gallery for ventilation and drainage purposes made the progress with the original Simplon tunnel less rapid than that now taking place.

The first Alpine tunnel, the Mont Cenis, is seven and a half miles long, and took over 13 years to construct. The St. Gothard, nine and three-quarter miles long, took nine and three-quarter years; the Arlberg, six and a quarter miles long, three years; the Simplon, twelve and a quarter miles long, six and a half years; and the Lötschberg, nine miles long, four years. At the present rate of progress Simplon II. should be completed in about four and a half years.

The following is a statement of the sewers and surface drains laid during 1913 at Vancouver, B.C.

	Feet.	Miles.

ELECTRICITY IN IRON AND STEEL MAKING.

The investigations that the U.S. Bureau of Mines is making into the metallurgical industries, the appliance of electricity to various processes, and especially in the manufacture of iron and steel, is given attention in Bulletin 67, "Electric Furnaces for Making Iron and Steel," just issued. It gives a historical review of the development of electric furnaces for making iron and steel, and discusses the problems which remain to be solved in the use of electric furnaces for the smelting of iron ores and the production of pig iron at a profit on a commercial scale. In discussing the electric furnace for the making of iron, it is stated that the electric furnace was not developed as a competitor of the blast furnace, but for the purpose of finding a furnace and a process that would be able to produce iron in those localities where blast-furnace practice was not feasible, or where the increasing cost of suitable fuel was becoming prohibitive to the existing practice of smelting in blast furnaces.

Broadly speaking, it is declared, it may be stated that the feasibility of smelting iron ores in an electric furnace depends upon the relative cost of either charcoal or coke and of electric power. As regards the latter, it must be cheap.

In those electric-furnace iron plants that are operating at the present time only hydro-electric power is used. The cost of producing power for electric-furnace work must, of course, vary with local conditions and hence depends upon the initial cost per kilowatt of installation. In general, there are few localities where the electric smelting of iron ores would be feasible with the electrical energy costing more than $20 to $30 per kilowatt-hour.

The second part of the report presents a brief historical review of the development of the electric furnace in the manufacture of steel up to the present time. The types of electric furnaces in commercial operation for the manufacture of steel and, in general, types which have not yet attained wide use, are described in detail. A description is given of the practice of the European and American electric-furnace steel plants, and a comparison made in a general was of the different types of furnaces and the more established methods of steel manufacture with the electric furnace process.

It is stated that the cost of making steel in the electric furnace varies with local conditions. The cost of power does not enter so largely into the final cost as it does in some other electro-metallurgical processes, especially the refining of molten steel. Plants are operating successfully under a power cost of 1 cent per kilowatt-hour in localities where material can be obtained at the price common to other processes. Plants such as the one at Ugine, France, have been established in remote localities, where the cost of power is very low, 0.2 cent per kilowatt-hour, but the cost of material is high.

For many years all high-grade steels were manufactured by the crucible process, but since the advent of the electric furnace there has been a gradual adoption of that furnace for refining steel. For the complete refining of the highest grades of steel the use of the electric furnace is now thoroughly established in Europe. Any product that can be made by the crucible process can be made by the electric furnace, and in most cases with cheaper raw materials and at a lower cost. In the electric furnace complex alloy steels can be made with precision. The high temperatures attainable facilitate the reactions and alloys need not be used so largely for the purpose of removing gas. Very low carbon steels can be kept fluid at the high temperatures. Steels free from impurities and of great value for electrical apparatus can be made. With the electric furnace large castings can be made from one furnace, whereas in the crucible process steel from several crucibles must be used. For small castings, which require a very high-grade metal free from slags and oxides, electrically refined steel is especially adapted. The electric furnace gives a metal of low or high carbon content as desired, hot enough to pour into thin molds and still free from slags and gases.

There is now a tendency among consumers of rail and structural steel to require a higher grade steel at an increased price rather than steel of acid Bessemer or even of basic open-hearth grade at a lower price. With the high cost of power that now prevails throughout the steel centres of the United States the electric furnace can not compete profitably with either the acid Bessemer or the basic open-hearth process in manufacturing steel of like grade from pig iron. It is in combination with either of these processes that the electric furnace seems destined to be prominent in steel manufacture. The cost of superrefining in the electric furnace the molten steel from either of these processes, exclusive of the cost of the molten steel, varies from $1.50 to $2.25 per ton, depending on the cost of power and the impurities to be removed.

THE ROAD MOVEMENT IN BRITISH COLUMBIA.

In the past 10 years the government of British Columbia has spent over $20,000,000 in roads and trails. There are in existence 20,000 miles of completed or partly completed roads, and in the recent budget speech of Hon. Price Ellison, Minister of Finance for British Columbia, it was stated that from all parts of the province have come numerous demands for roads, bridges, etc.

With a view to determining the requirements in the way of new roads, and in the bringing up to standard of existing roads, the Department of Works compiled estimates last year for the necessities of the immediate future. The information was derived from road superintendents throughout the province, and was supplemented by statements of the character of the country to be served and the reasons for their construction.

To link up the system of roads, as shown by the estimates received, will require the sum of $55,000,000, not including the requirements of the years to come. In a rougher way it has been estimated that between $100,000,000 and $125,000,000 will be ultimately required. When it is considered that since the census-taking of 1901 the population of the province has been increased by 350,000, in other words trebled, we can understand in some measure the increased demands on the treasury so created, not only in roads and trails, but in requirements of every character. Outside of the population of the various urban centres, there are 250,000 persons employed in the timber, fishery, mining and farming industries, and these are scattered from end to end of the province. The population of British Columbia will increase in a similar, if not greater, ratio for some years to come, and it is submitted as a wise and necessary policy that provision should be made as soon as possible for the inevitable needs of the near future.

The Maffel Schwartzkopf company of Berlin announces that it has defeated American competitors by obtaining a contract to deliver 14 high efficiency centrifugal pumps of 2,200 horse-power for the permanent pumping stations at Miraflores and Ancon, on the Panama canal.

ROAD BUILDING ECONOMICS

SOME NOTES ON BUILDING COSTS — RELATIVE 20-YEAR ECONOMY OF VARIOUS TYPES OF ROADS AND PAVEMENTS.

By REGINALD TRAUTSCHOLD, M.E.
Consulting Engineer, New York City.

THE advent and universal use of high-speed automobiles and heavy motor trucks have made the road problem one of the chief considerations of every municipality, whether it be a sparsely populated rural district, a village, a country town or a great city, and the economics of the subject are of greater general importance to-day than ever before. Various communities may require different classes of road construction but one and all must consider the economic value of the class of road they adopt. Road building being one of the oldest of undertakings there is an immense amount of reliable data on costs of construction, maintenance and deterioration of roads available for analysis, so that the question may readily be reduced to a simple business proposition and the relative economics of various types of road construction accurately recorded. In the following discussion, the various costs apply to average results attainable throughout the eastern section of the United States and though the same figures may not be capable of exact duplication in all sections, the relative economy of the various classes of road construction are proportionally accurate for any section, excepting, of course, for a particularly favored section where purely local facilities of material supply may favor some specific class of road building.

Before taking up a discussion of the various classes of roads, however, a few words on the financing of such undertakings is necessary. With few exceptions, roads are built by the federal government, the state legislature or a municipal board, and it makes no difference to the economics of the question whether the capital employed in building the roads is derived from direct taxation, the sale of bonds or whether the income from other source is employed, the capital invested in the roads must pay or carry a certain rate of interest. This value of the money may govern the economy of road construction in a certain locality—in one locality, one class of road may be relatively cheaper while in another, an entirely different class of road construction would prove the less costly, depending upon the rate of interest that the money employed in road building has to pay. Therefore, in order to make this discussion as comprehensive as possible, the capital charges and the interest charges will be kept separate. The establishment of a sinking fund for retiring bonds issued for road building operations does not materially alter the aspects of the case, retiring bonds before the completion of the road or during the life of the road simply reduces the net amount of interest paid on the capital directly involved in the road building operations by the use of other money that is just as valuable and entitled to the same profit.

Considered from a modern point of view, the available classes of road construction may be taken as macadam, paved and asphalt, and these three classes will be individually considered in that order. To arrive at a true valuation to put on any road the points that must be considered are: 1st, the initial cost of the road; 2nd, the average yearly maintenance charge of the road; 3rd, the life of the road, or the number of years that can be counted upon during which no extensive rebuilding is necessary; and 4th, the periodic rebuilding or renewal charge. The relative importance of these four conditions governing the economic value of the various classes of road construction are tabulated in Table I., for highways of 18-foot roadbed, to which reference will be made when considering the individual types of construction. The measure of economic value of the roads will be arbitrarily based on the total cost of the roads per mile for a period of twenty years as in such period the average road would have been subjected to the complete cycle of expenses to which it is subject and also as that length of time is frequently the period chosen for the life of construction bonds issued for raising the necessary capital.

TABLE I.

Average Road Building Costs Per Mile of 18-ft. Roadbed, etc.

Class of road construction.	Initial cost. $	Maintenance charge. $	Average life. Years.	Renewal charge. $
High-grade macadam	12,000	1,000	10	6,000
Paved roads, no foundations—				
Vitrified brick laid on edge	21,000	50	25	nil
Vitrified brick laid flat	11,000	55	1	11,000
Stone block	22,500	75	40	nil
Hard wood block	30,000	600	15	30,000
Soft wood block	23,000	800	12	23,000
Asphalt paving, no foundations	22,000	1,250	10	22,000

TABLE II.

Average Thickness of Concrete Foundations—Various Classes of Road.

Average cost, $1,100 per mile per inch depth, 18-ft. roadbed.

Class of road.	Thickness of concrete foundation.
Stone block paved	about 9"
Vitrified brick paved	4" to 6"
Hard wood block paved	about 8"
Soft wood block paved	about 9"
Asphalt paved streets	about 9"

Macadam Roads.—The severity of modern demands on roads is such that in considering roads of macadam construction one type only need be considered. The water-consolidated macadam construction has been almost entirely superseded by the tar macadam or similar construction. Without going into a detailed description of the method of construction of a high grade macadam road of modern development, such discussion being beyond the scope of this necessarily brief article, the average initial cost of construction per mile of 18-foot roadbed is very close to $12,000. The use of such roads is of necessity limited nowadays to comparatively small towns and as connecting highways between various cities or towns, etc., and are the most common class of rural highway construction. Their average maintenance charge should not, if the road is properly constructed, exceed $1,000 per mile per year, and they should not require renewal or reconstruction for a period of 10 years, at the expiration of which period they should be thoroughly overhauled and renewed at an average cost of about $6,000 per mile.

To arrive at the 20-year cost of a road, the measure of its true or net economic value, the various capital charges must all carry a certain rate of interest for the

period during which such investment is actually tied up in the road—i.e., from the time the investment is made until the end of the 20-year period that is taken as the measure of the economic value of the road. In algebraic form this is done in the derivation of Formula I., which equation conveniently expresses the 20-year cost of a high-grade macadam road of 18-foot roadbed in dollars per mile. The interest that a municipality has to pay for money is seldom less than 2 per cent. per annum and a community of any standing would rarely have to pay more than 5 per cent. These limits have considerable effect upon the 20-year cost of the road, however, and in the case of the macadam construction (see Example 1) the difference in the economic value of the road for which the capital was raised by an issue of bonds carrying interest at 2 per cent. and an issue bearing interest at the rate of 5 per cent., for instance, would be a sum equivalent to nearly 120 per cent. of the original cost of construction, the two issues of bonds being taken at equally advantageous terms.

Derivation of Formula I, 20-year cost of Macadam Highway per mile.

Macadam Highway—18-ft. roadbed.

Note:—I = yearly rate of interest.

	Capital charges.	Interest charges.
Initial cost per mile	$12,000	
Interest on initial cost (20-yr.)		12,000 x 20 x I
Renewal charge per mile (end of 10 years)	6,000	
Interest on renewal charge (10-yr.)..		6,000 x 10 x I
Maintenance charges per mile (18 x $1,000)	18,000	
Interest on 18 increments of $1,000 each, equivalent to		1,000 x 179 x I

20-year cost per mile = 12,000 + 240,000 x I + 6,000 + 60,000 x I + 18,000 + 179,000 x I.

20-yr. C = 36,000 + 479,000 x I. ....Formula I.

Example 1.

Required:—20-year cost of high-grade macadam road (18-ft. roadbed) per mile, money at 2, 3, 4 and 5 per cent. per annum respectively.

At 2% = 36,000 + 9,580 = $45,580.
3% = 36,000 + 14,370 = 50,370.
4% = 36,000 + 19,160 = 55,160.
5% = 36,000 + 23,950 = 59,950.

Paved Roads.—The second class of highway, the paved roads, are particularly adapted to modern requirements of resistance to traffic wear and to-day find an economic field in rural service as well as in its former particular field in cities and localities of congested traffic. The modern vitrified brick highway is the class of road construction that forms the common link between roads for urban and rural service and which at the present time has a tendency to revolutionize established road building practices.

Roads may be classified according to the two general kinds of service, urban and rural. The paved roads for city service are of stone block (blocks of granite or of stone of similar characteristics), vitrified brick and of hard or soft wood block construction. For country service the vitrified brick paved road has proved not only suitable but truly economic. These paved roads, one and all, require suitable foundations for supporting the paving and the most adaptable construction, ordinarily also the cheapest and most durable, is the concrete foundation. Old macadam roadbeds or similar foundations may be used in particular instances, but in a general consideration of the economics of road building it may be assumed that the correct and usual foundation for paved streets is that of concrete of thickness suitable for the service to which the road is to be subject. (See Table II.) The cost of excavation, etc., may also be grouped with the cost of the foundation so that in straight-ahead road work a reliably accurate average cost of foundations, including excavation, etc., is known that varies directly with the thickness or depth of foundations. This cost of foundations is approximately the same whatever class of paving is to be employed and a reliable figure for this expense is $1,100 per mile of 18-foot roadbed for each inch in thickness of foundations. Based on such general values, the 20-year cost of the various types of paved roads, the measure of the economic value of the road, will be taken up independently.

Stone Block.—Formerly the stone block paved road, such as is commonly known as "Belgian block roads" in many localities, was universally used for city service where the traffic was heavy and such construction is still by far the most lasting of pavements, a properly constructed road of such class having an average life of some 40 years, during which time the average total yearly cost of maintenance per mile of 18-foot roadbed should not exceed $75 per mile. Without going into the details of construction, etc., the initial cost of such a road without foundations is about $22,500 per mile. The thickness of foundation should be about 8 in. or 9 in., preferably the latter. In fact, certain of the more eminent road building engineers claim that heavy trucking on stone-paved roads demands a minimum thickness of 9 in. for supporting concrete foundations. The derivation of Formula II. is dependent upon the foregoing and clearly indicates the various interest charges that such class of road construction must carry. Example 2, giving the average 20-year cost of stone-paved roads built with capital of varying value, shows that, on account of the heavy initial expense and low maintenance charges of this class of road, the same proportional difference does not exist in the 20-year cost with capital of different value as when the initial cost is not so great and the maintenance expenses are greater.

Derivation of Formula II, 20-year cost of Stone Paved Roads.

Stone Paved Highway—18-ft. roadbed

Note:—I = yearly rate of interest.

	Capital charges.	Interest charges.
Initial cost per mile—		
No foundations	$22,500	
Concrete foundations	1,100 x t	
Interest on initial costs (20-yr.)—		
No foundations . .		22,500 x 20 x I
Foundations . . .		1,100 x t x 20 x I
Maintenance charges per mile (19 x $75)	1,425	
Interest on 19 increments of $75 each, equivalent to		75 x 100 x I

20-year cost per mile = 22,500 + 450,000 x I + 1,100 x t + 22,000 x t x I + 1,425 + 14,250 x I.

20-yr. C = 23,925 + 1,100 x t + (464,250 + 22,000 x t) I.
Formula II.

Example 2.

Required:—20-year cost of stone block paved road (18-ft. roadbed) per mile, money at 2, 3, 4 and 5 per cent. per annum respectively—concrete foundation, 9″ thick.

At 2% = 23,925 + 9,900 + (464,250 + 198,000) 0.02 = $47,080.00
3% = 23,925 + 9,900 + (464,250 + 198,000) 0.03 = 53,702.50
4% = 23,925 + 9,900 + (464,250 + 198,000) 0.04 = 60,825.00
5% = 23,925 + 9,900 + (464,250 + 198,000) 0.05 = 66,947.50

Vitrified Brick.—The constantly increasing use of vitrified brick for paving both urban and rural highways makes the consideration of this class of road construction of particular and important interest at this time. In fact, it is this class of road construction by which its enthusiastic advocates plan a certain upheaval of past road building methods. Unquestionably the construction is economical and possesses many excellent points for both city and country roads, so that its adoption in many instances is good economic practice, even if not so in all cases. In all cases, unless local conditions are extremely favorable to some other kind of road, the vitrified brick highway built of brick on edge and supported by a suitable concrete foundation is the construction possessing the greatest 20-year economic value—i.e., the construction with the lowest 20-year cost. Another method of brick construction is the use of the brick laid flat as paving. The former method requires nearly 50 per cent. more brick for a given area than does the latter and correspondingly the average normal life of the type requiring the greater number of brick is more than twice that of the latter method. The average life, during which only comparatively light yearly maintenance charges are necessary, of the two methods of laying the paving being from 20 to 25 for the one and about 10 years for the less durable construction. The initial cost of the two types of vitrified brick roads, disregarding the cost of foundations or excavation, which is about the same for either, is, for brick on edge, about \$21,000 per mile of 18-foot roadbed and, for brick laid flat, about \$11,000 per mile. The former construction, having a life of 20 years or more, requires no renewal expenses during a 20-year period, simply a quite nominal maintenance charge of about \$50 per mile per year; the latter, having a life of but 10 years, requires complete rebuilding at the expiration of that period at a cost of about \$11,000 per mile, and during the years in which simply a maintenance charge is necessary for keeping the road in good repair, this maintenance charge amounts to about \$55 per mile per year. For urban service, the thickness of the suitable concrete foundation is about 6 in., while for rural roads a 4-in. concrete foundation is generally all that is required. Formulæ III. and III.-a give the average 20-year cost of vitrified brick roads of

Derivation of Formula III and III-a, 20-year cost of Brick Highways.

Vitrified Brick Highway—18-ft. roadbed.
Note:—I =yearly rate of interest.

	Capital charges.	Interest charges.
Initial cost per mile—		
No foundations, brick on edge..	\$21,000	
Flat	11,000	
Concrete foundations	1,100 x t	
Interest on initial costs (20-yr.)—		
No foundations, brick on edge..		21,000 x 20 x I
Flat		11,000 x 20 x I
Foundations		1,100 x t x 20 x I
Maintenance charges per mile brick on edge (19 x \$50)	950	
Flat (18 x \$55)	990	
Interest on 19 increments of \$50 each, equivalent to		50 x 190 x I
18 increments of \$55 each, equivalent to		55 x 179 x I
Renewal charge (end of 10 years) brick laid flat	11,000	
Interest on renewal charge		11,000 x 10 x I

20-year cost per mile (brick on edge) = 21,000 + 1,100 x t + 420,000 x I + 22,000 x t x I + 950 + 9,500 x I

20-yr. C = 21,950 + 1,100 x t + (429,500 + 22,000 x t) I.
Formula III

20-year cost per mile (brick laid flat) = 11,000 + 1,100 x t + 220,000 x I + 22,000 x t x I + 990 + 9,845 x I + 11,000 + 110,000 x I.

20-yr. C = 22,990 + 1,100 x t + (559,845 + 22,000 x t) I.
Formula III-a.

Example 3.

Required:—20-year cost of vitrified brick roads (18-ft. roadbed) per mile, money at 2, 3, 4 and 5 per cent. per annum—concrete foundations, 4" and 6" thick.

Brick laid on edge (urban service, foundations 6" thick).

At 2% = 21,950 + 6,600 + (429,500 + 132,000) 0.02 = \$39,780.00
3% = 21,950 + 6,600 + (429,500 + 132,000) 0.03 = 45,395.00
4% = 21,950 + 6,600 + (429,500 + 132,000) 0.04 = 51,010.00
5% = 21,950 + 6,600 + (429,500 + 132,000) 0.05 = 56,625.00

Brick laid on edge (rural service, foundations 4" thick).

At 2% = 21,950 + 4,400 + (429,500 + 88,000) 0.02 = \$36,700.00
3% = 21,950 + 4,400 + (429,500 + 88,000) 0.03 = 41,875.00
4% = 21,950 + 4,400 + (429,500 + 88,000) 0.04 = 47,050.00
5% = 21,950 + 4,400 + (429,500 + 88,000) 0.05 = 52,225.00

Brick laid flat (urban service, foundations 6" thick).

At 2% = 22,990 + 6,600 + (559,845 + 132,000) 0.02 = \$43,426.90
3% = 22,990 + 6,600 + (559,845 + 132,000) 0.03 = 50,345.35
4% = 22,990 + 6,600 + (559,845 + 132,000) 0.04 = 57,263.80
5% = 22,990 + 6,600 + (559,845 + 132,000) 0.05 = 64,182.25

Brick laid flat (rural service, foundations 4" thick).

At 2% = 22,990 + 4,400 + (559,845 + 88,000) 0.02 = \$40,346.90
3% = 22,990 + 4,400 + (559,845 + 88,000) 0.03 = 46,825.35
4% = 22,990 + 4,400 + (559,845 + 88,000) 0.04 = 53,503.80
5% = 22,990 + 4,400 + (559,845 + 88,000) 0.05 = 59,982.25

18-ft. roadbed, the former for roads where the paving is laid on edge and the latter where the brick is laid flat, the derivation of which explains the various charges that such roads must carry. Example 3 gives the average 20-year cost of these roads for both city and country service and a comparison of these costs with similar costs for any other class of road construction indicates that for a 20-year period such roads are apparently the most economical that can be constructed and explains the keen interest that has recently been taken in this class of road by administrative bodies.

Wood Block.—Noiselessness is the main advantage of any wood block paving and, though their slipperiness in wet and wintry weather is a drawback, they find a true economic and satisfactory use in city service. Both hard and soft wood blocks are used, the former usually simply being dipped in a mixture of tar and pitch or creosote oil before being laid, while the impregnating mixture is forced into the latter type of wood block under suitable pressure. Both kinds of blocks are laid upon foundations of concrete, floated in cement and grouted in either cement or pitch. Expansion and contraction, which ordinarily is greater and harder to control with the hard wood block, is taken care of by providing an expansion space along either curb, which space is usually filled with puddled clay. As in the case of all city streets, the width of roadbed is usually more than 18 feet, but, as the cost of any class of road depends directly upon the width of its roadbed, the 20-year cost of such roads will also be considered as 18 feet, so that ready companison of its true economic value can easily be made with the other classes of construction that have been and will be considered. The hard wood block paving is the more costly but it also has a somewhat longer life than the soft wood block paving and the latter carries a heavier maintenance charge per year. The various charges incidental to the two classes of wood block paving are itemized in the derivation of the Formulæ IV. and V., the former of

which gives the average 20-year cost of hard wood block roads per mile and the latter the average 20-year cost of similar roads constructed of soft wood block paving. Examples 4 and 5 give the average 20-year costs of hard and soft wood block roads respectively per mile built on concrete foundations of standard depth or thickness for city service with capital commanding from 2 to 5 per cent. per year. These examples would tend to indicate that the soft wood block road is in reality of higher economic value, lower 20-year cost, than the somewhat more durable hard wood block road, even though the foundations for the former are advisably somewhat thicker. Practice also confirms this deduction if the soft wood blocks are suitably and thoroughly impregnated with a mixture of tar and pitch or similar compound.

Derivation of Formula IV, 20-year cost of Hard Wood Block Highway.

Hard Wood Block Highway—18-ft. roadbed.

Note:—I=yearly rate of interest.

	Capital charges.	Interest charges.
Initial cost per mile—		
No foundations	$30,000	
Concrete foundations	1,100 x t	
Interest on initial costs (20-yr.)—		
No foundations		30,000 x 20 x I
Concrete foundations		1,100 x t x 20 x I
Maintenance charges per mile 18 x $600	10,800	
Interest on 18 increments of $600 each, equivalent to		600 x 184 x I
Renewal charge per mile at end of 15 years	30,000	
Interest on renewal charge (5-yr.)..		30,000 x 5 x I

20-year cost per mile = 3,000 + 600,000 x I + 1,100 x t + 22,000 x t x I + 10,800 + 110,800 x I + 30,000 + 150,000 x I.

20-yr. C = 70,800 + 1,100 x t + (860,400 + 22,000 x t)I.
Formula IV.

Example 4.

Required:—20-year cost of hard wood block road (18-ft. roadbed) per mile, money at 2, 3, 4 and 5 per cent. per annum respectively—concrete foundation 8″ thick.

At 2% = 70,800 + 8,800 + (860,400 + 176,000) 0.02 = $100,328.00
3% = 70,800 + 8,800 + (860,400 + 176,000) 0.03 = 110,692.00
4% = 70,800 + 8,800 + (860,400 + 176,000) 0.04 = 121,056.00
5% = 70,800 + 8,800 + (860,400 + 176,000) 0.05 = 131,420.00

Derivation of Formula V, 20-year cost of Soft Wood Block Highway.

Soft Wood Block Highway—18-ft. roadbed.

Note:—I=yearly rate of interest.

	Capital charges.	Interest charges.
Initial cost per mile—		
No foundations	$23,000	
Concrete foundations	1,100 x t	
Interest on initial costs (20-yr.)—		
No foundations		23,000 x 20 x I
Concrete foundations		1,100 x t x 20 x I
Maintenance charges per mile 18 x $800	14,400	
Interest on 18 increments of $800 each, equivalent to		800 x 181 x I
Renewal charge per mile at end of 12 years	23,000	
Interest on renewal charge (8-yr.)..		23,000 x 8 x I

20-year cost per mile = 23,000 + 460,000 x I + 1,100 x t + 22,000 x t x I + 14,400 + 144,800 x I + 23,000 + 184,000 x I.

20-yr. C = 60,400 + 1,100 x t + (788,800 + 22,000 x t)I.
Formula V.

Example 5.

Required: 20-year cost of soft wood block road (18-ft. roadbed) per mile, money at 2, 3, 4 and 5 per cent. per annum respectively—concrete foundation, 9″ thick.

At 2% = 60,400 + 9,900 + (788,800 + 198,000) 0.02 = $ 90,036.00
3% = 60,400 + 9,900 + (788,800 + 198,000) 0.03 = 99,904.00
4% = 60,400 + 9,900 + (788,800 + 198,000) 0.04 = 109,772.00
5% = 60,400 + 9,900 + (788,800 + 198,000) 0.05 = 119,640.00

Asphalt Paved Streets.—The popularity of asphalt pavement for city service lies not only in the freedom from noise but also in the ease with which such roads can be kept clean. The softening of the paving surface, if subjected to even the summer temperature of many localities, limits the use of this class of road to cities in the temperate zone, in even which localities the softening of the asphalt surface has much to do with the very high maintenance charge that is necessary to keep such roads in good repair. A maintenance charge of $1,250 per mile of 18-foot roadbed and proportionally greater for wider roads is about the charge that has to be carried even when the asphalt is laid on a good and firm concrete foundation. Without such foundation, the maintenance charge is even greater, but the more stable construction will only be considered. Asphalt paving laid over good stone paving supported on suitable concrete foundations also makes an excellent road, but such road is only built when local requirements demand the "noiseless" road where formerly a high-grade stone-paved but noisy road had proved satisfactory, so cannot rightfully be a road with an individual economic value. The 20-year cost of such road can, however, be easily ascertained by the use of the formula applying to the construction of a stone-paved highway in conjunction with the following equations pertaining to asphalt-paved streets. The economic value of such combination road would be high, as its life would be little, if any, longer than that of an asphalt street built on suitable concrete foundation without the intervening layer of stone paving.

Derivation of Formula VI, 20-year cost of Asphalt Paved Streets.

Asphalt Paved Highway—18-ft. roadbed.

Note:—I=yearly rate of interest.

	Capital charges.	Interest charges.
Initial cost per mile—		
No foundations	$22,000	
Concrete foundations	1,100 x t	
Interest on initial costs (20-yr.)—		
No foundations		22,000 x 20 x I
Concrete foundations		1,100 x t x 20 x I
Maintenance charges per mile 18 x $1,250	22,500	
Interest on 18 increments of $1,250 each, equivalent to		1,250 x 170 x I
Renewal charge per mile at end of 10 years	22,000	
Interest on renewal charge (10-yr.)..		22,000 x 10 x I

20-year cost per mile = 22,000 + 440,000 x I + 1,100 x t + 22,000 x t x I = 22,500 + 123,750 x I + 22,000 + 220,000 x I.

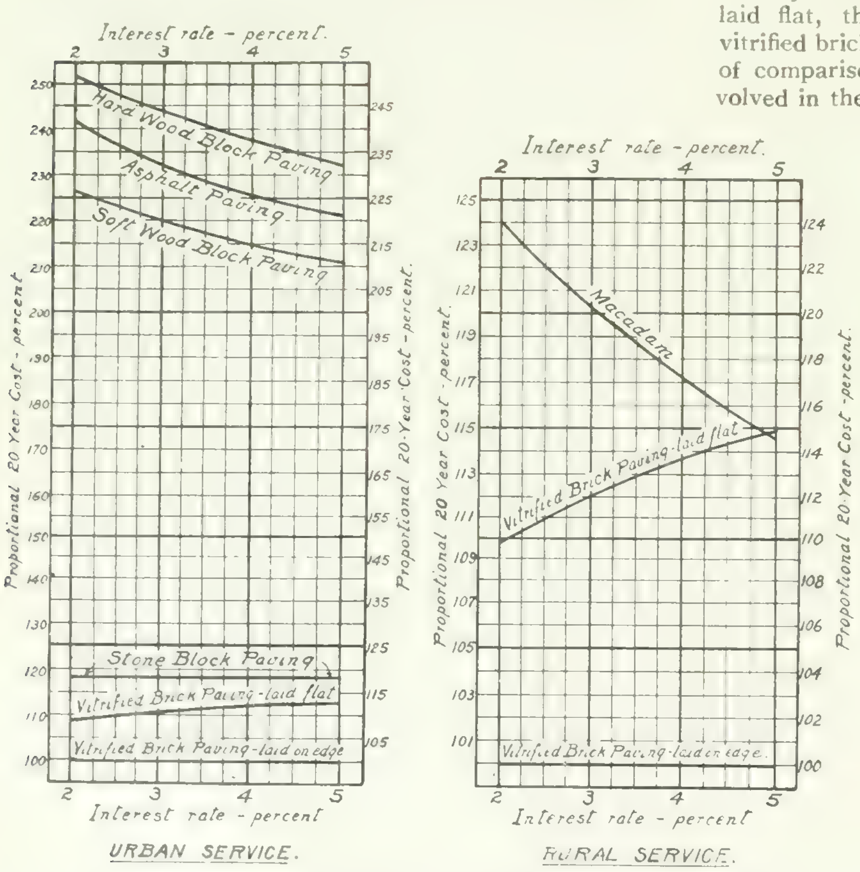
20-yr. C = 66,500 + 1,100 x t + (783,750 + 22,000 x t)I.
Formula VI.

Example 6.

Required:—20-year cost of asphalt paved street 18-ft. roadbed) per mile, money at 2, 3, 4 and 5 per cent. per annum respectively—concrete foundation, 9″ thick.

At 2% = 66,500 + 9,900 + (783,750 + 198,000) 0.02 = $ 96,035.00
3% = 66,500 + 9,900 + (783,750 + 198,000) 0.03 = 105,852.50
4% = 66,500 + 9,900 + (783,750 + 198,000) 0.04 = 115,670.00
5% = 66,500 + 9,900 + (783,750 + 198,000) 0.05 = 125,487.50

The life of a well-laid and well-constructed asphalt street is rarely much more than ten years, at the end of which period the street requires complete renewal at a cost of about $22,000 per mile of 18-foot roadbed. Notwithstanding these heavy expenses, the asphalt paving continues to be extensively used and does make an excellent city highway where traffic is not too severe. In fact, its 20-year cost (average) shows that its economic value in urban service is greater than that of the hard wood block street and about equally more expensive than the soft wood block construction, the 20-year cost of an asphalt road being about a mean between similar costs of hard and soft wood block paved streets. The usual foundation construction for paved streets is ordinarily resorted to for the asphalt street as well, so the average cost of foundations is applicable to such construction. The various charges that the ordinary high-grade asphalt highway is called upon to carry are all itemized in the derivation of Formula VI., by which equation the average 20-year cost of an 18-foot highway of asphalt paving per mile can be readily ascertained. Example 6 gives the average cash outlay necessary for such roads built on concrete foundations 9 inches thick, the depth of foundation required for satisfactory city service, with capital of values of from 2 to 5 per cent. per annum.



Figs. 1 and 2.—Relative 20-year economy of various classes of roads built with capital bearing interest at from 2 to 5 per cent. per annum.

A comparison of the various examples that have been given shows that the cheapest road, as far as 20-year cost is concerned, is, both for rural and urban service, the vitrified brick highway built of brick on edge. Comparing the 20-year cost of other classes of roads with that of roads paved with vitrified brick laid so as to develop the greater life and representing such basic cost as 100 per cent., the relative 20-year economy, as measured by the proportional 20-year cost, of various classes of roads is graphically depicted on Figs. 1 and 2, the roads being classed as to their use for urban or rural service. A study of these charts emphasizes certain interesting points, among which not the least interesting is that the past road building practice has not been as incorrect as modern revolutionists in the science of building roads have implied. It is true that what may be termed a relatively modern vitrified brick road is the most economical in 20-year cost for both city and country service, but that in order to realize the full economy of the brick road the brick must be laid on edge. The cheaper construction (cheaper in initial cost) of laying the brick flat, though relatively economical when money for road building is cheap, decreases in economy as the money used from construction increases in value. For urban service, the vitrified brick road with brick laid flat is little more economical in 20-year cost than the stone block road when the value of the capital so invested approaches 5 per cent. per annum. For rural service, the type of lesser economical brick construction is less economical than high-grade macadam when money is worth 5 per cent. With the solitary exception of the vitrified brick road with brick laid flat, the proportional 20-year cost—the economic vitrified brick construction serving in all cases as the basis of comparison—of all roads diminish as the capital involved in their construction becomes more valuable. This does not mean that it is cheaper to build with expensive capital but that, should a road of relatively high 20-year cost be constructed with money commanding a high rate of interest, the proportional increase in cost compared to that of a vitrified brick highway (20-year cost) would not be as great as when capital can be obtained at more advantageous terms. The chart showing the relative 20-year economy of rural roads is of particular interest in that it brings out the fact that the small community which has to pay a high rate of interest for its money is in a much better position to afford a high-grade macadam road—in fact, such road is usually the only possible one for such a community, owing to its comparatively low initial cost—than a more important community more fortunately situated, as far as obtaining money at a low rate of interest is concerned.

The great discrepancy in the proportional 20-year cost of wood paved or asphalt streets and of the stone or vitrified brick paved streets for city service cannot be taken as truly indicative of the respective economic value of the "noisy" and the "noiseless" streets, for between these two varieties comparison can only be made when a true valuation can be put on noise, or, rather, lack of noise. Local requirements must decide such point and the convenience of the public be the gauge of economic value of the respective varieties. However, the urban service chart shows that the six available classes of road naturally divide themselves according to their freedom from noise and a comparatively wide choice of construction exists for either the "noisy" or the "noiseless" street.

LAST SPIKE IS DRIVEN

At the Nechako River Crossing, British Columbia, the last link in the construction of the Grand Trunk Pacific Railway was undertaken recently. Construction on this road was started in 1905 and 2,000 miles of track have now been laid, the last spike being driven 371 miles east of Prince Rupert and 1,375 miles from Winnipeg.

The main line of the Grand Trunk Pacific extends from Winnipeg to Prince Rupert, B.C., a distance of 1,746 miles. The line first follows the Assiniboine Valley in Manitoba and runs through a district well settled before the advent of the railway. From Portage la Prairie west the district traversed was practically a new one, and one in which colonization and development have been due to the railway. Saskatoon and Edmonton are the only cities which existed and which had railway facilities prior to the advent of this railway. Now the country is dotted with towns in all stages of development.

The following is a list of branch lines covered by Grand Trunk Pacific Branch Lines Company:—

	Length, Miles.	Total Miles.
Manitoba—		
Harte-Brandon branch	25	25
Saskatchewan—		
Melville-Canora	55.2	
Melville-Regina	98.4	
Regina-Boundary	155	
Regina-Moose Jaw and North West	108	
Prince Albert Branch	111.8	
Battleford Branch	48.5	
Cut Knife Branch	50	
Biggar-Calgary	104.06	
		730.06
Alberta—		
Tofield-Calgary Branch	201.5	
Alberta Coal Branch	56.4	
Mountain Park Coal Branch (operated)	30.24	
		288.14
		1044.10

Of the above the following is now in operation. The entire mileage will be in operation during 1914:—

	Miles.
Melville-Canora	55.2
Melville-Regina	98.4
Regina-Boundary	155
Regina-Moose Jaw and North-west	90.2
Prince Albert	67
Battleford	48.5
Cut Knife	33.6
Biggar-Calgary	104.06
Tofield-Calgary	201.5
Alberta Coal Branch	56.4
Mountain Park Coal	30.24
	940.10

Under the Grand Trunk Pacific Saskatchewan Railway Company's charters construction has been begun on the branch from Talmage to Weyburn, and the line is completed except for track work, and will be in operation during 1914. Weyburn Branch, 15 miles in length.

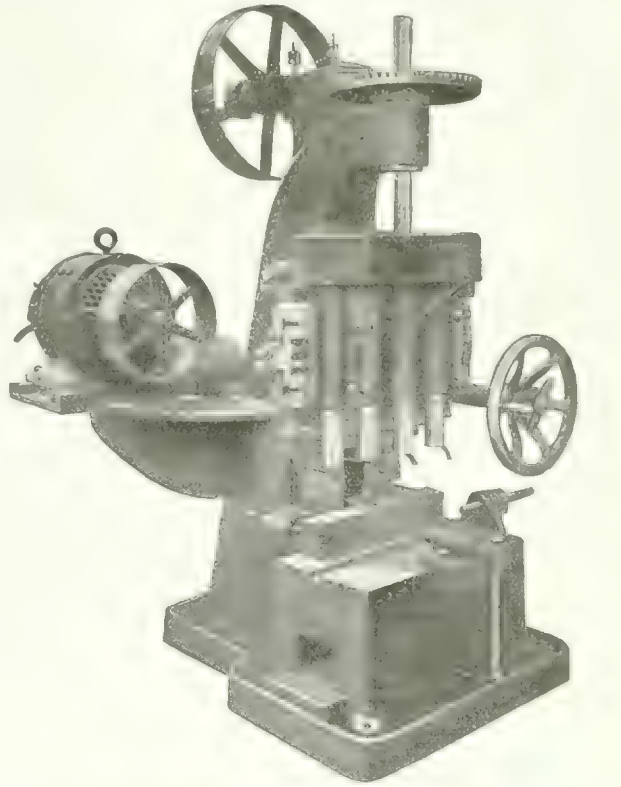
	Miles.
Total mileage of branch lines completed and in operation	940.10
Begun and to be completed	119.00
Total to be in operation in 1914	1059.10

The annual meeting of the shareholders of the Steel Company of Canada was held on April 27 at Hamilton, when the following officers were re-elected:—C. S. Wilcox, president; C. A. Birge, vice-president; Robert Hobson, vice-president and general manager; directors, Charles Alexander, Providence, R.I., W. D. Mathews, Toronto; John Milne, William Southam, Hamilton; Sir Edmund Osler, Toronto; F. H. Whitton, Hon. William Gibson and Lloyd Harris, Brantford; S. H. Champ, secretary-treasurer. The directors' report, which stated that last year was the best in the history of the company, was adopted. It was stated that the plant was just now running irregularly, as work came in. The opinion was expressed that the change in the tariff would benefit the company.

A NEW RAIL DRILLING MACHINE.

The rail drilling machine shown in the illustration possesses some new and interesting features.

The three holes for the fish-plate bolts and the hole for the rail bond are all drilled at the same time. The three right-hand spindles are for the bolt holes, and these are arranged so that the distance between centres of the holes can



be adjusted from 3½ to 9 inches. The left-hand spindle is for the rail-bond hole; it keeps a constant distance of 6 inches from the last bolt hole.

All the spindles are mounted on a saddle and can be moved vertically in unison. The saddle is counter-weighted and has two changes of power feed in addition to hand adjustment.

The machine is made by the Newton Machine Tool Works, Philadelphia. A 10-h.p. Westinghouse electric direct current motor furnishes the power.

The following is a statement of work in connection with the waterworks distribution system at Vancouver, B.C., for the year 1913. Details of mains laid are as follows:—

Size.	Pipe Laid, Lin. Ft.
2-inch	10,655
4-inch	794
6-inch	78,962
8-inch	36,449
12-inch	31,128
24-inch	21,300
32-inch	21,300
	200,588

Details of valves placed in 1913 are as follows:—

2-inch	[illegible]
4-inch	31
6-inch	287
8-inch	100
12-inch	[illegible]
18-inch	1
24-inch	4
32-inch	2
	[illegible]

No. of hydrants placed this year, 1913	229
No. of hydrants in use in city	1,657

COAL AND COKE PRODUCTION IN BRITISH COLUMBIA, 1912-13.

The preliminary review and estimate of mineral production, 1913, published by the British Columbia Bureau of Mines in Bulletin No. I., 1914, states that preliminary returns received show a gross production in 1913 of about 2,577,000 long tons of coal, as compared with nearly 3,026,000 tons in 1912. The quantity made into coke was 440,000 tons, leaving 2,137,000 tons as the net production of coal. The quantity of coke made was rather more than 285,000 long tons, which constitutes a record in production of coke in the province, the highest previous year's output having been that of 1905, of 271,785 tons. For purposes of comparison the following table is shown:—

		1913.	1912.	1911.	1910.	1909.
Coal, gross	tons, 2,240 lbs.	2,576,886	3,025,709	2,297,718	3,139,235	2,400,600
Less made into coke	"	440,192	396,905	104,656	339,189	394,124
Coal, net	"	2,136,694	2,628,804	2,193,062	2,800,046	2,006,476
Coke made	"	285,123	264,333	66,005	218,029	258,703

When the year opened the Canadian Collieries (Dunsmuir), Limited, had succeeded in considerably increasing the output from the mines of its Comox Colliery, notwithstanding that the United Mine Workers of America had for several months required its members to abstain from working in those mines owing to the persistence of the company in its determination not to recognize that organization. Having got its production almost up to normal quantity at its Comox mines, the company next gave its attention to its Extension mines, at which a strike had also been declared by the union. Other measures having failed to prevent progress being made at Extension Colliery as well as at Cumberland (Comox Colliery), the United Mine Workers of America declared a strike at all coal mines on Vancouver Island, with the result that the miners of the Western Fuel Company, Nanaimo, had to violate their unexpired agreement with that company and cease work. The strike also affected the mines of the Pacific Coast Coal Mines, Limited, operating at South Wellington, Morden, and Suquash, and of the Vancouver-Nanaimo Coal Mining Company working the Jingle Pot mine near Nanaimo. With the exception of the last-mentioned company, the operators continue to decline to accede to the demands of the United Mine Workers of America, and the position at the close of the year was that the Canadian Collieries Company was working its Cumberland mines to full ordinary production capacity, and its Extension mines to about the extent it was doing when the general strike was called at the end of April; the Western Fuel and the Pacific Coast Coal Mines Companies were working with comparatively small forces of non-union men, yet were producing some coal; and the Vancouver-Nanaimo Company had all the union men it could find work for.

While the labor troubles at Vancouver Island mines had caused a decrease in production of coal to the estimated extent of approximately 596,000 tons, there were increases in Nicola and Crows Nest Districts of about 57,000 and 90,000 tons, respectively, which reduced the decrease in the coal production of the province as a whole to a net total of about 449,000 tons. The gross production of the several districts was as follows:—

	Tons of 2,240 lb.
From Vancouver Island mines	962,620
From Nicola and Similkameen mines	262,768
From Crows Nest mines	1,351,498
Total quantity of coal produced	2,576,886
Less made into coke	440,192
Net quantity of coal produced	2,136,694

Leaving out of account the present interruption to production at some of the Vancouver Island coal mines, the statement appears to be warranted that on the whole the coal mining industry of the province is in a progressive condition. That this is so is demonstrated particularly by the considerable developments of mines and large additions to plant and machinery made by three of the four companies operating on Vancouver Island. Some particulars of important development work and new equipment now referred to were given in the Annual Report of Minister of Mines for 1912.

In the Nicola field, the Inland Coal and Coke Company made the largest output of coal of any in the district—about 116,000 tons, compared with 31,000 tons in 1912. No considerable addition to plant was made. The chief new development work done was driving a new slope—No. 5. High railway freight rates prevented the Nicola Valley Coal and Coke Company from extending its market, so its output of coal was comparatively small—about 110,000 tons, as against nearly 143,000 tons in 1912. In addition to continuing operation of mines previously worked, the company opened Nos. 7 and 8 mines. In No. 7, situated near the top of Coal Gully hill, the main slope has been sunk 500 feet and is being extended; from this a number of working places have been opened off, giving the mine a present output capacity of nearly 200 tons of coal a day from a 16-foot seam of excellent coal. In No. 8 there is a 6-foot 6-inch seam which is promising, but sufficient development has not yet been done to determine its value as a producer. The company could mine and ship 750 tons a day if called upon, but there is not a present demand for so much. Even the Canadian Pacific Railway Company's requirements of coal are smaller now than in the past, as many oil-burning locomotives have been substituted for coal-burners. The Diamond Vale Collieries Company increased its small output from 3,300 tons in 1912 to 6,300 tons in 1913, and the Pacific Coast Colliery Company made a beginning with a production of 462 tons of coal.

There was little change in the Similkameen field. The output of 28,800 tons made by the Princeton Coal and Land Company was only a few hundred tons larger than in 1912. The United Empire Company made little progress, its output having been quite unimportant. The Columbia Coal and Coke Company's property changed ownership, and its new owners commenced to develop a different part of the property to that in which the first management of the Columbia Company had done much work without profitable result.

Both the Crow's Nest Pass Coal Company and the Hosmer Mines, Limited, made a larger production of coal in 1913 than in 1912. The output of the first-mentioned company was approximately 1,041,000 long tons of coal, gross, or, after deduction of 333,000 tons made into coke, 708,000 tons net. Its coke output was 225,480 long tons, as against nearly 219,000 tons in 1912. During the year the company developed what is known as "B" seam, which lies 320 feet above No. 1 seam of the Cool Creek measures, and thus provided for a present addition of about 500 tons a day to the producing capacity of its Coal Creek Colliery. At its Michel Colliery, the company developed two new mines above the old workings of No. 8 on the north side of the valley, and in this connection a skip incline was constructed to convey the coal down the mountain to the tipple level, the incline grade starting at 30 per cent. and increasing to 60 per cent. toward the lower end. The skips or cages carry 8 tons of coal and are easily controlled by rotary multiple brakes over a distance of 1,280 feet in eighty seconds. A profitable production is expected from these new openings in the ensuing year. Much prospecting work was done on the south side of the valley, where a new seam was found about 150 feet above No. 3 seam. A working section of about 10 feet of coal of generally good quality was opened here. As indicating favorable working conditions throughout the last year, it may be mentioned that the output of the company's Coal Creek Colliery exceeded that of 1910 (1911 was not a full year as regards operation of mines) by about 230,000 tons, while the quantity of coke made at the ovens at Fernie was about 9,600 tons greater than that of the previous record year, and nearly 44,000 tons higher than the coke production of 1910. There is promise of considerable improvement at both Coal Creek and Michel Collieries in 1914, especially at the mines of the latter, and it is hoped that the economic development work now in progress at the Coal Creek mines will materially enhance the general results.

Only a brief summary of the year's operations at the colliery of the Hosmer Mines, Limited, has been obtained. The output of coal was about 237,500 long tons, gross. Approximately 107,000 tons were used in making coke, leaving a new output of coal of 130,500 tons. The amount of coke made was about 59,600 long tons. The increase for 1913 as compared with 1912 was, therefore, in gross production of coal, about 49,000 tons (or 14,000 tons net), and in coke 14,200 tons. There was not any new mining development during the year. Improvements and additions to the plant included double-tracking "B" incline, and adding another drum to the engine operating the same; installing an 8-foot diameter Sheldon-Keith wheel-fan for ventilating "No. 2 B" south mine; and providing a steam locomotive for the rock bank and boiler coal.

At the Corbin Colliery, a fire, due to spontaneous combustion, necessitated the closing of No. 1 mine in April, and it was kept closed throughout the remainder of the year. No. 4 mine was opened after No. 1 was closed; it is on a seam which is really a branch off the No. 1 seam, and has a present production of about 250 tons a day. No. 3 mine, known as the "Big Showing," was provided with transportation facilities, the railway to it from Corbin, eight miles in length, having been completed in the first half of the year. This mine is situated nearly 1,000 feet higher than No. 1, which is near the level of the valley. In No. 1 mine the coal seam is nearly vertical and varies greatly in size. W. W. Leach, of the Geological Survey of Canada, described it as varying from a minimum thickness of 10 feet to a maximum of nearly 250 feet. This great difference, he said, may be due to compressed monoclinal folding. At the upper mine the coal has been stripped of the overburden near the top of the hill, and it is shown in a synclinal basin about 370 feet in width, the thickness of the coal near the centre having been proved by drilling to be more than 100 feet. During the summer and autumn, coal in No. 3 mine was worked in open cuts by a steam shovel, and sent down the switchback standard-gauge railway for shipment. The snowfall being heavy, open-cut working is not practicable in winter, but about 150 tons of coal a day is being mined underground here. A Marcus screen has been purchased for this colliery, but it will not be put in until next spring.

Of the new coal fields in various parts of the province there is little to report so far as concerns the probable early production of coal. In the Upper Elk River District, so far as known, there was not any advancement made toward the utilization of the large quantity of coal occurring in that part of the province, which has been estimated by D. B. Dowling, of the Geological Survey of Canada, as covering an area of 140 square miles, and containing approximately 14,000,000,000 tons of coal that can be mined. Until railway transportation shall be provided, this important district will remain undeveloped. Neither in the northern part of Cariboo District nor in the North Thompson River country, in both of which coal is known to occur, is there present prospect of production. Prospecting work done on coal measures on Graham Island of the Queen Charlotte group, has not yet resulted in any production of coal worth mentioning. More development work has been done on coal properties in parts of the Skeena District tributary to the Grand Trunk Pacific Railway, the construction of which is now nearing completion, and some attention has also been given to properties in Groundhog basin, in the northern part of Skeena District, but the latter is without transportation facilities and not much progress has been made.

A LARGE CONCRETE BRIDGE.

A concrete bridge which is being built at Pasadena, Cal., is the longest and highest bridge in the South-West. The roadway, 28 ft. wide between kerbs, is 160 ft. above the channel of the Arroyo Seco, a stream flowing beneath the finest residential section of the city, and the length of the [illegible] apart from its long sweeping curve is the series of arches, the largest of which is 223 ft. from centre to centre of the piers, while there are two spans of 151 ft. and six of 113 ft. each. The arch spans consist of two continuous elastic arch ribs carrying spandrel columns and in part spandrel walls. These support cross beams with cantilevered ends. The massive piers rest upon the boulders and gravel of the stream bed and are tested to 11,000 lb. per sq. ft. Cement to the extent of more than 10,000 barrels was required for the concrete, which is reinforced with corrugated bars of the strength of from 60,000 lb. to 70,000 lb.

The [illegible] ly been equipped with machinery for testing materials of construction, comprising appliances for performing impact, tension, torsion and transverse strain tests.

A communication [illegible] ers at Edmonton by Bosley Brothers of Brooks, Alberta, proclaims confidence in the presence of natural gas near Edmonton. They stated that they had a proposition to put before the civic authorities whereby the city could own its wells and have an [illegible] It would only to have to be piped 5 miles to the centre of the city. They stated also that there was no limit to the supply; the pressure would be good; [illegible] would not exceed 1,300 feet.

A RETAINING WALL AT SMALL COST.

By C. D. Norton.

THE retaining wall illustrated here was designed for the village of Orono, Ont., on the Canadian Northern Ontario Railway, some 50 miles east of Toronto. It was necessary to widen the street running parallel to the long wing, and as the existing culvert was

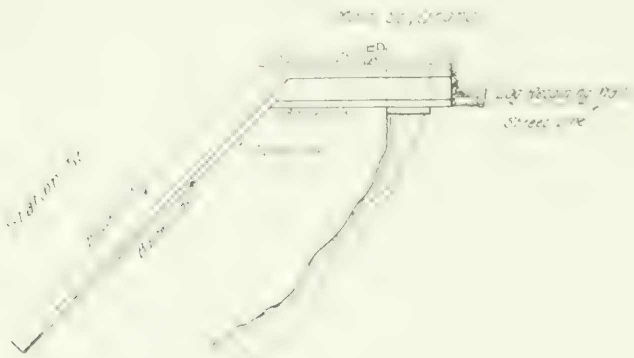


Fig. 1.—Location of Retaining Wall at Orono, Ont.

in very bad condition, it was decided to replace both it and the cedar retaining wall with a concrete structure. The old culvert was of rubble laid in lime mortar, which had become disintegrated by the weather. In addition, roots of plants and trees had penetrated the masonry, rendering it very unstable.

The limited sum of $500 was at the disposal of the village trustees, which necessitated careful study to secure a substantial structure at a minimum cost.

The loose masonry was pulled down until there was a good foundation for the concrete, and on the rest of the wall the excavation was carried down far enough to secure a good bottom, the average depth being 2 feet; the earth excavated was carefully packed after the forms were removed.

To be literally correct, the wall could hardly be termed "concrete," rubble laid in cement being more appropriate. Forms were used in the usual manner, a layer of concrete poured in, on which field-stone was carefully packed until the whole space was filled, care being taken that the stones did not touch each other. This procedure was carried out until the wall was complete.

After the forms were removed the wall was left to cure for six weeks, and then the backing was carefully tamped in.

The contractor was paid at the rate of $4 per cubic yard for the concrete, and the excavation was paid for at cost plus 10 per cent., the contractor finding everything. He used a motor-driven, ¼-yard cylindrical mixer, and had to haul his cement, lumber, and machinery five miles. Stone and gravel cost nothing, gravel being hauled half a mile. Labor cost at the rate of 17½ cents per hour. An exact record of the cost could not be obtained, as the work was very intermittently done, and the contractor had no system of cost-keeping.

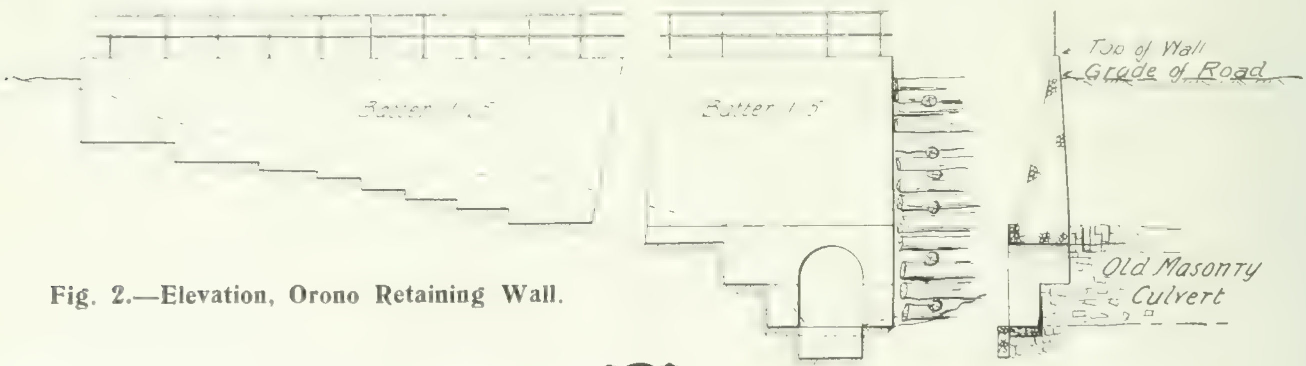

Fig. 2.—Elevation, Orono Retaining Wall.

HEAT JUDGING IN FOUNDRIES.

It is the custom in foundries to judge the heat of the molten metal by the eye, before pouring it into the moulds, and in comparatively few foundries is that use made of the pyrometer which its importance merits. The prevailing rough-and-ready method must result in a large proportion of defective work. No matter how accurate a man's eye may be, it will be evident that in every-day foundry work he has to use it under varying conditions and it is next to impossible that his eye can follow these as quickly as they change. It is not an easy matter to train the eye to judge the heat of molten metal from its color; but it may be said at once that it is impossible for the judgment to be accurate unless the light in which the metal is viewed is invariably the same.

The principal drawback to the use of pyrometers in furnaces in which the temperature is upwards of 1,000° C., is the destructive effect of the heat on the mechanism of the instrument. This difficulty, in fact, was not overcome until the introduction of the radiation or optical methods of temperature measuring. In radiation pyrometers it is possible to measure the heat radiated from the hot body, in various ways, by the effect it produces. Among these may be mentioned that of measuring the electricity produced when the radiation is made to heat a joint between dissimilar metals and that of measuring the alteration in the electrical resistance of a metal ribbon when exposed to radiated heat. In a particularly interesting form of pyrometer some of the heat rays from a hot body are concentrated by means of a concave mirror on to one junction of a small thermo-electric battery. When the junction is heated it sets up an electro-motive force, which is caused to pass through a galvanometer which is calibrated in degrees of temperature. The necessity of employing a galvanometer is a weak spot, as by it complications are introduced which it were well to be without. It is necessary, for example, that the instrument should stand on a perfectly level bed. It must not be exposed to outside magnetic influence, and it is of vital importance that the wires from the pyrometer to the galvanometer should be well insulated, as any leakage of current would affect the reading. A form of pyrometer was recently brought out, however, by the inventor of the one mentioned, which has all the advantages and none of the disadvantages of the older form. In it the galvanometer and the insulated wires are done away with, and it is consequently far more easily handled. The construction is quite simple and there is little or no possibility of errors occurring when the instrument is used. Instead of the heat rays, as in the earlier form, being concentrated on a small thermo-electric cell, they are focused on a small spiral strip formed of two ribbons of dissimilar metals. When heated this spiral gradually unwinds by reason of the different coefficients of expansion of the two metals, and, as can readily be seen, it is not a difficult matter to devise a means whereby the amount of this movement can be measured and expressed in degrees of heat.

CONTENTS OF THIS ISSUE.

APPLICATION OF SCIENCE TO INDUSTRY.

The art of producing from one form of substance other forms for which there is a demand is known as Industry. When this production is accomplished by a process which incurs the least cost and turns out the best article commensurate with that cost, the art is experiencing maximum efficiency. Few industries have reached the sphere of this stage of perfect operation.

To Science has been applied the term "exact knowledge"—an exceedingly broad definition but a very significant one when the scientist is considered in relation to industrial operations. Reflection upon the accomplishments of the past century attributes its many epoch-making inventions to this exact knowledge. Science, in the brief space of 100 years, has produced facilities that have transformed civilization, by a series of innovations that arose out of the subtle method of theory and experiment.

What might be achieved if Science and Industry were made to work more in sympathy with each other is to be learned from the results of the application of the former to almost every industrial process in Germany. The "Made in Germany" tag has attained prominence in commercialism the world over. In the coal industry there is an example of the effect of Science, that would form the basis of some exceedingly interesting literature. The liquid products of distillation, for many years discarded as useless, have, under the revealing eye of scientific investigation, given us the coal tar dyes. Similarly, naphthalene, formerly a waste product of the same process, produces indigo. Creosote, tar and pitch, better known to the engineer than the others, are each a manifestation of scientific research.

These widely known instances in the development of industry, as well as innumerable revelations of a similar nature, preach excellent sermons. They did not happen by chance. The scientist, with his training in exactness, and his consequent elasticity of mind, brought them about, and established the laws governing their manufacture. They were the reward of most careful vigilance—nothing being allowed to escape unnoticed or uninvestigated.

The question is: Are we in our own Canadian industries keeping our various processes under the trained eye of the student of Science? Do we employ him in our shops and factories to study the effects of the forces that are at work there, and the quality of the materials upon which they operate?

This is being done in European countries and in the United States. To these countries are going many of the men whom our Canadian universities are training to apply Science to Industry.

UNIVERSITY INSTRUCTION IN HIGHWAY ENGINEERING.

Apart from the general course of training in the principles of civil engineering as presented in our Canadian universities and colleges, it is interesting to note the response which many of them have tendered to meet the demand for a special training in matters pertaining directly to road and pavement work. Undoubtedly this adaptation, requiring in several incidents an amendment of policy, has been occasioned by the disturbance which motor-driven vehicles have caused in the hitherto well-established art of road-making. This problem, together

with the increasing demand for facilities of transportation, which has made itself heard in various portions of the country, has precipitated an enormous demand for scientific instruction. The elementary principles upon which the practice of road-making and maintenance had long been based, had, to a certain extent, given place to a set of rules, broad enough in scope to be applicable to the average problem which, in previous years, had only to contend with horse-drawn traffic. The automobile, in conjunction with the steel tire and horse's hoof, has sent us back to elementary principles with respect to many things, and the co-operation of the universities in an endeavor to solve the road problem of the present day is timely and worthy of strong support.

A few years ago the University of Toronto established a course in highway engineering, optional to students of the fourth year in the department of civil engineering. It consists of a course of lectures and laboratory work of two hours and six hours per week respectively, throughout the entire session. The course deals with the design and construction of roads and pavements and careful analyses and tests of materials, their characteristics, durability and strength.

In McGill University instruction in this branch consists of a brief course of lectures on city pavements in connection with the third year work in municipal engineering. The topics taken up include methods of construction, cost, durability and desirability of various kinds of pavements; grades and cross-sections; methods of assessment of costs, and methods of maintenance and cleaning. There is no laboratory course devoted specifically to road materials, but there are those in the tests of cement and concrete, as well as a very thorough course in the design of bridges for highways and railways. It is intended to increase the instruction now given by a course of 26 lectures and 26 laboratory periods; and also to install equipment for standard tests of materials.

At the Ecole Polytechnique, Laval University, regular lectures on the subject of highway engineering have been given for the last 20 years, the course covering all matters pertaining to road-making and street pavements. Several years ago a laboratory was installed for the testing of paving materials. These tests include impacts, abrasion, hardness, toughness, cementation, absorption, specific gravity and fracture in connection with materials used for paving and macadam. The department is also equipped for the testing of bitumens, asphalts, tars and oils, as well as other compounds used in surfacing macadam. The course of lectures includes those on legislation relating to roads and streets.

For the past five years in the department of civil engineering in the School of Mining, Queen's University, there has been a course in municipal engineering in which one hour per week and approximately 25 hours per session have been devoted to highway work. A revision of the curriculum this year adds to this an hour per week in the third year devoted to municipal engineering, in which case one-half the lectures will be taken up with highway work.

The third year students in civil engineering and forestry in the University of New Brunswick have a course of about 25 lectures in highway construction. With the exception of cement testing, no laboratory work has been given in this connection. The department of agricultural engineering in the University of Saskatchewan includes highway construction in its third year course. In addition a portion of a short course for farmers which this university provides was devoted this year to a series of lectures on road construction by Mr. H. S. Carpenter, chief engineer to the Highway Commission for the Province of Saskatchewan.

Students in civil engineering at the University of Manitoba receive a lecture course of two hours per week for one term in highway construction. There is under contemplation an extension in the near future to include laboratory work as well as the study and inspection of the various materials used in road-making.

The University of Alberta has no distinctive course in highway engineering except as part of the course in municipal engineering.

The University of Mt. Allison College, through its affiliation with McGill University and Nova Scotia Technical College and the Ontario Agricultural College, have no courses on the subject, but touch upon it in the lectures of other courses.

SASKATCHEWAN LOCAL GOVERNMENT BOARD.

The extent of local improvement work in the various municipalities in Saskatchewan is shown by the fact that during the four months of existence of the Saskatchewan Local Government Board, debentures for $5,540,752.14 were authorized. Of that amount, school districts received authorization to issue debentures amounting to $689,225; rural telephone companies, $361,400; rural municipalities, $6,000; towns, $289,400; villages, $8,900, and cities, $4,185,827.14. Almost half of the debentures being issued by the seven cities of Saskatchewan are those providing for local improvement works at Regina.

PROPOSED TOWN-PLANNING BILL.

At the forthcoming International Conference on City Planning, Toronto, May 25-27, a draft town-planning act will be submitted to the delegates present by a special committee appointed by the Commission of Conservation. After being amended in accordance with the resolutions of the Conference, copies will be sent to each provincial government, urging them to enact legislation along the lines proposed.

As now drafted, the bill provides for the preparing and carrying out of town-planning projects by a local board in each city or town, subject to the approval of a central town-planning board for the whole province. Projects will apply chiefly to land likely to be used for building purposes, but may, in certain circumstances, include land already built upon or land unsuitable for building. Provision is made for compensation of private owners if injuriously affected and for the local authority recovering half of the unearned increment if property values are increased. The central board may act on its own initiative if the local board fails to do its duty or if no local board exists.

EDMONTON BRANCH, CAN. SOC. C.E.

On May 1st an Edmonton Branch of the Canadian Society of Civil Engineers was formed, with headquarters at the University of Alberta. Fortnightly meetings will be held. The following are the officers elected for the year: Chairman, W. Muir Edwards, M.Sc., C.E., Professor of Civil Engineering, University of Alberta; secretary-treasurer, L. B. Elliott, Department of Public Works, Canada. Executive Committee—Commissioner of Works, J. Chalmers; W. R. Smith, N. M. Thornton, D. J. Carter, J. D. Robertson, and R. H. Parsons.

NEW INCINERATING PLANT AT REGINA, SASK.

DESCRIPTION OF A 60-TON INCINERATING UNIT RECENTLY ADDED TO PREVIOUS 50-TON UNIT — RESULTS OF TESTS SHOWING COST OF OPERATION UNDER VARYING CONDITIONS.

IN the early part of 1907 Regina decided to erect an incinerating plant to care for the refuse of that city. The contract was let to the Decarie Incinerator Company, of Minneapolis, Minn., and a 50-ton, single unit plant of the steel waterjacketed type was installed at that time. The incinerating furnace proper was constructed entirely of steel 10 ft. square by 12½ ft. high, inside dimensions, with a 4-in. water space on all four sides and with a 2-ft. steam and water space above the crown sheet. Along two sides of the furnace were placed 1½-in. extra heavy pipes connected to the crown sheet at the top and to the firebox sheets at the bottom. The pipes were spaced at 9-in. centres and bent so as to form a basket grate to receive the refuse which was charged in from the wagons on the floor above through four 3-ft. square hopper openings in the crown sheet. By this means the refuse was lodged upon an indestructible grate about 3 ft. above the lower or cast iron shaking grates on which the material was finally consumed, giving the fire free access to all parts of the newly charged material, without in any way obstructing the draft or deadening the fire below.

This 50-ton unit was installed in a brick building with wooden driveways to the upper floor, enabling the refuse

Fig. 1.—Exterior View of Plant.

wagons to deposit their loads directly into the furnace. Nothing but natural draft was provided and that was furnished by a steel stack 135 ft. high and 4 ft. diameter at the top.

At that time it was thought that a plant of 50 tons daily capacity would be amply large for several years to come; but the phenomenal growth of the city during the past few years made it plain, late in 1912, that in a short time the plant would need to have additional capacity. Consequently, steps were immediately taken by the city commissioners, through Dr. M. R. Bow, medical health officer, and Mr. J. A. Bertwistle, chief sanitary inspector of the city, to outline a larger refuse disposal system of sufficient size to care for the city in the future. Regina

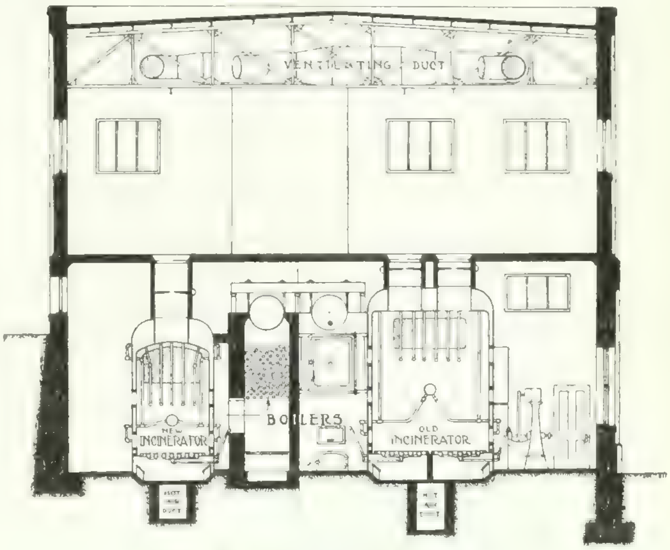

Fig. 2.—Cross-section of Plant.

already had under construction additions to their 2½-million-gallon sewage disposal plant, which is located in the extreme northwestern portion of the city on the banks of Wascana Creek. The pumps to be installed here were to be electrically operated, and immediately the question arose as to the advisability of utilizing the heat generated by the burning refuse to help furnish the power for operating these pumps. It was known that the heat from a city's refuse is converted into electrical energy in many European cities and used to produce a source of revenue. It was also known that the incinerating plant built by the Decarie Incinerator Company, at Minneapolis, had for years been furnishing the power to light several wards of the city. Consequently, it was decided to investigate the feasibility of such an arrangement in connection with the sewage plant.

This company agreed to construct a modern plant at the site of the sewage disposal works for the sum of $64,000. The plant was to consist of a new 60-ton unit, with the old 50-ton unit, which had operated very satisfactorily during the past 5 years, renovated and moved into the same building, making in all a plant with a guaranteed capacity of 110 tons in 24 hours. The plant was to be equipped with two 100-h.p. B. & W. water tube boilers, together with forced and induced mechanical draft.

In May, 1913, the contract was awarded to the Decarie Incinerator Company at the above figure. On December 1st, 1913, the new plant commenced operation.

The terms of the proposal as furnished by the contractors to the city were:—

"The new unit to be installed should have a capacity of incinerating 60 tons of refuse in 24 hours and the old unit, after being remodelled and installed in the new plant, should have a capacity of incinerating 50 tons of refuse in 24 hours. The refuse to consist of kitchen garbage, combustible material, manure and dead animals mixed together in proportions as created by the city of Regina from day to day, no attention being paid as to the selection of any particular kind of refuse or garbage; it being understood that manure would constitute 60% of the refuse to be destroyed.

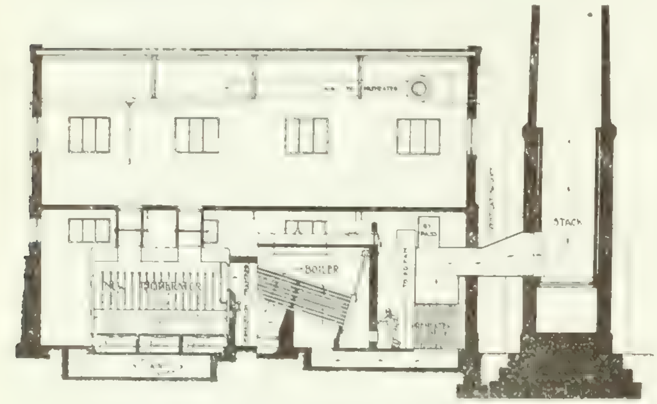

Fig. 3.—Longitudinal Section.

"All material delivered to the incinerator would be destroyed without creating any noxious odors or gases.

"The total cost of operation would not exceed 65c. per ton, and if credit would be given for power developed by the boilers, at the rate of 70c. per 1,000 lb. of steam, the cost would be reduced by one-half, and if 30% of the total refuse should be dry combustible the addition of fuel would be unnecessary."

The guaranteed cost of operation is claimed to be somewhat higher than usual, owing to the large percentage of manure that had to be handled. According to the results of the final tests, as given in this article, however, the operating cost came to only 40c. per ton when burning 60% of manure. The old plant had a guaranteed cost of 50c. per ton and operated at an average of 30c. per ton for the five years previous; but, of course, it handled no such percentage of manure as the new plant was required to dispose of. In fact, in the old plant the city had difficulty in consuming the manure without additional fuel, as this plant was equipped with no mechanical draft whatever.

The new plant is located on the bank of Wascana Creek, the building being of concrete, brick and steel construction 44 ft. x 54 ft., inside dimensions. Two sides of the first floor of the building were formed by the concrete retaining walls. As shown in Fig. 1, the remainder of the building is of brick. The hopper or charging floor is of reinforced concrete supported on steel beams. The standard gauge street car track, on which the refuse is delivered to the plant in special dump-cars, passes through the building at the hopper floor level. The roof is of 3-in. concrete slab construction covered with tar and gravel roofing, supported on steel purlins and trusses. I-beam trolley tracks are attached to the under side of the trusses over each unit, on which chain blocks operate to raise the heavy cast iron hopper covers and carcasses that are brought to the plant for destruction.

All material as it is delivered to the plant is dumped directly into the furnaces from the cars, without storage of the refuse being necessary. Drain connections to the sewer as well as water and steam connections are provided on the charging floor for keeping the cars and the floor in a sanitary condition.

The incinerating furnaces and boilers, together with all the other necessary machinery, are located on the lower or operating floor, the general arrangement being as shown in Figs. 3 and 4. The two separate units are of 60 and 50 tons capacity, as stated above. Each unit consists of an incinerator, combustion chamber, and one 100-h.p. B. & W. boiler. A pre-heater or regenerator for heating the forced draft is located between the boilers and the chimney. An American Blower Company's induced draft-fan, direct connected to an 11-in. x 8-in. automatic high-speed self-oiling steam engine is provided, as well as a forced draft-fan of the same make direct connected to a 9-in. x 7-in. steam engine of similar construction. Four $5\frac{1}{2}$ x $3\frac{1}{2}$ x 6 Marsh feed pumps are provided; one for each incinerator and one for each boiler.

The chimney is 5 ft. in diam. at the top and 125 ft. high. It is of radial brick construction with an octagonal common brick base, set on a heavy concrete foundation just outside the building wall.

The new incinerator is of the waterjacketed type which had proved itself so economical in repairs and operation in the old 50-ton plant. As can be noted from Figs. 2, 3 and 5, it is made with larger and narrower dimensions than the old unit; being 6 ft. wide by 18 ft. long, and is 10 ft. high, inside dimensions. It has 4-in. water legs and a 2-ft. steam and water space above the crown sheet. With these proportions the labor necessary for stoking is materially reduced, and as the number of stoking doors is much smaller, not nearly so much cold air is drawn into the furnace. As will be noted from the two sectional views, the piping forming the basket-grates in both the new and old units is of the latest construction used in this make of furnace.

The longitudinal header, connecting the two end water spaces and into which all the 2-in. basket pipes are

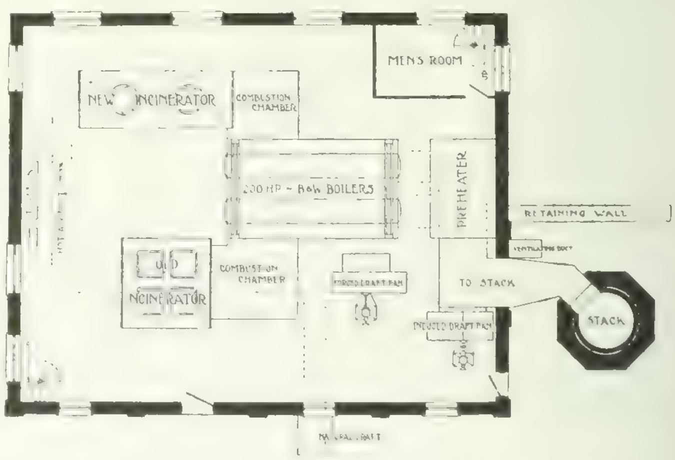

Fig. 4.—Plan of Operating Floor.

connected at their lower ends, is made of 12-in. extra heavy pipe in the new incinerator and 8-in. extra heavy pipe in the old one. As will also be noted from the sectional illustrations, the pipes forming the basket grate do not connect into the inside plates but come through the water-leg and, by means of union tees and elbows, connect into the outside sheets. This arrangement enables

these pipes to be kept thoroughly clean by means of plugs located in the tees.

Operation.—The refuse enters from the upper floor through the balanced doors in the brick-lined hoppers and drops onto the basket grate. As it burns in this position, and on the shaking grates directly beneath, the gases pass into each respective brick-lined steel-cased combustion chamber, where they are thoroughly mixed and burned before entering the boilers through the side wall directly over the boiler grates. The gases then pass through the water tubes of the boiler, giving up a large amount of their heat to the generation of steam in these tubes. It will be noted here that by this arrangement the boilers can be operated simultaneously with the waste gases and with coal in case the heat from the refuse is not sufficient to maintain a constant pressure, conditions being liable to occur in wet weather or when the heat value of the refuse is exceptionally low.

After leaving the boilers the gases pass under the floor and up through the pre-heater, or regenerator, direct to the chimney; or they may be drawn through the induced draft fan to the chimney, as the conditions may require.

hindering the operation of the other sections of the grate. The use of this hot forced draft has shown itself to be the most essential feature in the burning of manure and saving of additional fuel. In case only natural draft is used, as in starting up when the steam pressure is down, an opening is provided to the outside of the building so that air can be drawn directly into the ash pit, thereby removing the necessity of opening the ash pit doors. This feature is especially valuable in the winter time when the lower floor is well sealed up to prevent the cold air from coming into the building.

Each unit is also provided with a by-pass direct from the respective combustion chambers to the chimney, thereby enabling the boilers and pre-heater to be entirely cut out in case, for any reason, repairs should be necessary, or if occasion should arise, the boilers and incinerators can be operated entirely independent of each other.

The boilers are installed to work at a pressure of 160 lbs. per sq. in., the plan being to use the steam from the boilers for the generation of electric current for the sewage pumps. The generator set has not yet been installed, but very likely will be in the near future.

Fig. 5.—Interior View, Showing New Incinerator, Boilers and Pumps.

Fig. 6.—Forced Draft and Induced Draft Fan Installation.

The one pre-heater and the induced draft fan serves for both units or for either one of the two units if only one unit is in operation. The pre-heater contains 740 2½-in. boiler tubes expanded into ⅜-in. steel plate heads, the gases passing through these tubes on their way to the stack. The air supply for the forced draft fan is taken through a duct leading from the ceiling of the upper floor to the pre-heater, thus removing all the foul air from the building that might come from the refuse as delivered. This air is drawn through the pre-heater around the tubes through which the hot gases are passing, taking up enough of this heat from the waste gases to raise the temperature of the air going into the forced draft fan to the temperature of from 150° to 400° F. The forced draft fan forces this heated air through concrete ducts below the floor, as indicated in Fig. 4, to the ash pits of the two incinerators. It enters the pits directly under the grates through suitable control nozzles at a maximum pressure of 4½ inches. It might be stated here that the ash pits of each incinerator are divided into sections, so that the forced draft can be shut off entirely in any one section and the fire cleaned on that section of grates without

The incinerators are designed to operate at 100 lbs. per sq. in. steam pressure, but in the continuous operation of the plant as a steam generating station each incinerator operates as a feed water heater for its respective boiler, the fans being operated by the steam from the boilers. The piping is arranged so that in starting up the plant, or, when the boilers are shut down, the incinerators can furnish the necessary steam for the fans and pumps.

The blow-offs from the incinerators lead into the respective combustion chambers and those from the boilers lead to the atmosphere through a 5-in. pipe. The exhausts from the pumps and fan engines pass through a 6-in. pipe directly into the base of the chimney.

The installation of the complete equipment, except the old incinerator itself, was completed and the plant commenced operation December 1st, 1913. It was agreed by the city that a test of the capacity of the 60-ton unit would determine the fulfilment of the guarantees, as the city could not, without great inconvenience, supply more than 60 tons of refuse in 24 hours. The 50-ton unit could

not be dismantled at the old plant until the new plant was in operation and consequently the installation of the old unit in the new plant has just recently been completed after it has been overhauled and equipped with the new system of piping.

Near the site of the street car barns, the city has erected a loading station and a stable.* It is here that collection wagons deliver their loads of refuse into the dump-cars.

The loading station is a brick and reinforced concrete building, two stories high, 46 ft. x 146 ft., and was erected at a cost of $16,000. A siding of the municipal street railway runs through the building at ground level, and in this siding are placed the 5-yd. steel dump-cars especially designed for this service. The loaded collection wagons enter on the second floor by means of an approach at the end of the building and dump their contents directly into the cars. At present it is only necessary to make one trip per day to the plant with the loaded train of cars, as the storage capacity of the empty cars is enough to hold the city's daily amount of refuse at this season of the year.

The stable is also of brick construction, erected at a cost of $23,000, and provided with single stalls for 32 teams, together with 4 box stalls. The wagons are housed under the second floor of the loading station.

The first of the three test periods held on the new plant occurred on December 1, 1913, under the supervision of the builders, with the following results:—

Date of test	December 1st, 1913.
Duration of test	22 hours.
Grate area	108 square feet.
Material incinerated	Manure, 57,240 lbs. Garbage, 55,480 " Fruit, 2,800 " Fish, 3,500 " Horses, 1,500 "
Total material destroyed	60.26 tons.
Percentage of manure	47.5 per cent.
Percentage of ash	10.0 per cent.
Refuse burned per hour	2.74 tons.
Equiv. incineration in 24 hrs.	65.76 tons.
Equiv. incineration per sq. ft. grate	50.7 per cwt.
Labor required	1 engineer 22 hrs. at 50 cents ... $11.00 3 firemen 22 hrs. each at 30 cents . 19.80 $30.80
Labor cost per ton	51.1 cents.
Fuel required	Coal, 200 pounds. Kindling, ¼ cord ... $3.00
Total cost of fuel	$3.00.
Fuel cost per ton refuse	.049 cents.
Total cost of operation per ton refuse	.56 cents.

Although this first test fulfilled all the guarantees of the builders, the city desired to run another test with the regular city crew operating the plant. They also desired to have the requisite quantity of manure on hand to make up the 60% that was stipulated in the contract. Consequently, on December 12, 1913, a second test was run with the city's crew operating the fires, the following results being obtained:

Date of test	December 12th, 1913.
Duration of test	9.5 hours.
Grate area	108 square feet.
Material incinerated	Manure ....23,310 lbs. Garbage and refuse.24,460 " 47,770 lbs.
Total material destroyed	23.89 tons.
Percentage of manure	48.8 per cent.
Percentage of ash	10.0 per cent.
Refuse burned per hour	2.51 tons.
Equiv. incineration in 24 hrs.	60.24 tons.
Refuse burned per sq. ft. grate per hour	46.5 lbs.
Labor required	1 engineer 9½ hrs. at 50 cents .... $4.75 3 firemen 9½ hrs each at 25 cents 7.12 $11.87
Labor cost per ton	49.7 cents.
Fuel required	No coal used. Small amount kindling wood to start.
Total cost fuel required	0.50 cents.
Total cost per ton refuse	2.1 cents.
Total cost operation, per ton.	51.8 cents.

The plant demonstrated in this second test, also, that it could be operated within the guaranteed cost by the city's own men, but again the 60% of manure was not available. Consequently, a third and final test was held on January 7, 1914, the results being as follows:—

Date of test	January 7-8th, 1914.
Duration of test	19.0 hours.
Grate area	108 square feet.
Material incinerated	Garbage and refuse.48,870 lbs. Manure ......74,100 " 122,970 lbs.
Total material destroyed	61.49 tons.
Percentage of manure	60.3 per cent.
Percentage of ash	10 per cent.
Refuse burned per hour	3.24 tons.
Equiv. incineration in 24 hrs.	77.76 tons.
Refuse burned per sq. ft. grate per hour	60.0 lbs.
Labor required	1 engineer 19 hrs. at 50 cents .... $ 9.50 2 firemen 19 hrs. each at 25 cents 9.50 $19.00
Labor cost per ton	30.9 cents.
Fuel required	½ cord wood, $4. 200 lbs. coal, $1.
Total cost fuel required	$5.00.
Fuel cost per ton refuse	8.1 cents.
Total cost operation per ton refuse.	39.0 cents.

On April 23 a report was made by John A. Penton of Cleveland, secretary of the American Pig Iron Association, to the general assembly of the association held at New York. The report showed that the pig iron industry in the United States is being operated at a loss of $1,000,000 a month. It further declared that the average loss on all pig iron sold by 85 per cent. of the pig iron manufacturers and merchants north of the Ohio River during February last was $1.15 per ton. Unfilled orders on the books of the members of the association on March 1 amounted to 1,714,801 tons; and as a result of these conditions, many furnaces have been shut down and plants are in the hands of receivers.

As a result of the building of the Assouan Dam on the Nile, the primary object of which was to conserve water for irrigation purposes, the development of 5,000 horsepower in the form of electrical energy has been made possible. Different purposes to which this power can be applied are being considered. One horsepower will manufacture two tons of calcium cyanamide in one year, and thus the Assouan power could turn out 100,000 tons per annum—that is to say, £900,000 worth of the fertilizing agent most extensively required in Egypt. Another use the power could be put to, as shown by Sir William Willcocks' recent work, is summer irrigation, on an even more extensive scale than at present provided for. It is also proposed to utilize the power in the weaving of silk

THE HIGHWAY SITUATION IN ONTARIO.

THE proposals for preliminary organization and investigation, made in the recent report of the Public Roads and Highways Commission, are very deserving of the attention of road officials, not only of Ontario but throughout the Dominion. The commission, consisting of Messrs. McLean, Rankin and McGrath, chairman, was appointed on July 31st, 1913, to make a preliminary survey of the immense problem in the province of Ontario and to lay down a set of proposals. Their report contains the result of their investigations, together with a number of considerations and suggestions of considerable importance.

Their suggestion is that the province embark upon a definite 15 years' policy, and establish a form of organization carefully designed to be simple and flexible, and to fit itself into the developments of the future. The work to be done, they conceive, should be of a permanent character, but as permanent roadways are constructed, proper measures should be taken to ensure efficient maintenance, and the expenditure on maintenance must grow as a service of this sort is built up. The method to be pursued is the fixing of a certain scale of expenditure during the prescribed period; the devoting of a portion of that sum to the raising of a bond issue whereby considerable capital sums could be obtained at once for permanent work; and the extinguishing of these bonds at a fairly rapid rate, so that they shall not outlast the roads which they will represent. The total capital expenditure which they propose for this period is $30,000,000, the securities to be issued in instalments as the growing organization is able profitably to spend the money. Allowing for interest and sinking fund outlays, they estimate the annual expenditure upon permanent roadways towards the close of the period at approximately $2,500,000. This would be, roughly, at the rate of $1 per head for the population of the province, or about the payment per head in France for the maintenance of a superb system of highways. The money should be raised from various sources—province, counties, cities and towns, and should be expended by various bodies, a cardinal principle being that the people themselves should be as close to the expenditure and the responsibility as possible.

For the expending of this sum of money, and the conduct of so important, so continuous, and so technical an undertaking, a permanent administrative body is necessary. It should be under a minister of the Crown, and under him should be a permanent head for the administrative work which will be inevitable. A chief engineer will be necessary, for a high quality of skilled and scientific work is demanded if the enterprise is to be economically and successfully undertaken. In addition, there is scope for an unpaid advisory commission—comprising three men of affairs, their function being to consult with the permanent head, chief engineer, and minister, on technical (as distinguished from general) policy, and to assist in interesting the general public in a project which every citizen should regard as his own affair.

The commissioners are of opinion that a satisfactory organization cannot be ready before 1915, and that the coming season should be devoted to a rapid preliminary study of physical conditions. The actual mileage of the roads has been ascertained, but less is known upon the all-important subject of the available supplies of road-building material The nucleus of the central organization, and the permanent advisory commission, if appointed, might with profit prosecute the following lines of investigation:—

(1) A motor survey of the main-travelled roads; parties suitably composed might traverse these roads and form an estimate of their present condition and the amount and kind of work necessary to bring them up to a satisfactory standard.

(2) A study of the township roads prosecuted by selected engineers, to determine the condition of the more important ones, with a view to their improvement.

(3) A traffic census, designed to give fairly exact information as to the volume of traffic now borne by the highways.

(4) A study of the market roads in counties not now under the Highway Act, with a view to suggesting to each of such municipalities a suitable system of market roads.

(5) A determination of equitable suburban areas for each city, as suggested herein.

(6) A survey of the proposed Toronto-Hamilton and Ottawa-St. Lawrence roads; and certain investigations of the Queenston-Hamilton or other roads of a similar character.

The report sets forth the views of the commission upon the subject of the classification of roads. The general classification of roads and their division into groups for control are matters of primary importance in dealing with public highways. The cost of construction and maintenance, and the methods to be applied, are largely in proportion to the amount of traffic on the several roads; and an intelligent classification is basic, in apportioning the cost fairly, and in providing for efficient methods of construction and finance.

The province of Ontario may be divided as follows:

(a) Well settled areas, about	30,000	sq. miles
(b) Areas containing scattered settlements, or at present available for settlement, about	30,000	"
(c) Areas likely to remain for many years in a state of nature, but containing wealth in the form of timber, minerals, fisheries, and fur-bearing animals, about	200,000	"
Total area	260,000	"

The area of England and Wales, with a population of over 36,000,000, is under 60,000 square miles. Thus the settled area in Ontario, whose road system is the subject of the present inquiry, is about one-half that of England and Wales, and the total area whose equipment with roads is a prospect of a measurably near future, is about the same as that of England and Wales.

The closely settled area of Ontario at present is traversed by about 50,000 miles of roads, and in addition there are colonization roads, which the Provincial Government builds in the newer districts to encourage settlement, and often in advance of it. These colonization roads raise a set of problems so diverse from those of the highways of the settled portions of the country that your commissioners do not recommend that they be detached from the organization now in charge of them, and they shall henceforth omit them from the purview of this report. Their main concern is with the 50,000 miles of roadways in the 30,000 square miles of the settled and organized portion of the province.

The highways of Ontario seem to fall into the following sub-divisions:

County or Market Roads.—These fall into the following subdivisions:

(a) Suburban Roads.—These are close to the cities, and have to bear perhaps the heaviest traffic of any rural highways; partly because some of them are used for interurban traffic, partly because of the traffic created in a belt about the city by the propinquity and the demands of its great consuming population. Often the farmers living in these belts are in a sense citizens of the towns whose market they supply, and whose shops they frequent. The cities are specially interested in the roads of this class, which have a direct bearing upon the food prices which prevail in them, and upon the comfort of their citizens.

(b) Interurban Roads.—These are main travelled highways between centres of population, and are subjected to considerable use by persons other than farmers.

(c) Rural Market Roads.—These are main travelled highways used mainly by farmers on their way to the centres where they buy and sell, but used by many whose properties do not border them. Often many of the township roads to be noticed in a moment discharge their traffic into these small arteries of local traffic. It is a function of these roads to lace together the various townships and rural communities.

Township Roads.—These constitute the vast mass of the roads of the countryside; they serve mainly the farmers who live alongside them, and for the most part lead into main travelled or market highways.

In the present circumstances, the general condition of rural roads being so indifferent, interurban and market routes have a tendency to shift; as one stretch of road is improved or another allowed to deteriorate, so that the volume of traffic borne by a particular route is not an absolute proof that under a proper organization of the road system of the province, it would not be a main travelled road. A road census would show what amount of travel is furnished to-day by a given district, and the channels which it now takes; but considerations such as the density of population, the productivity of the land, railway construction, possible or probable developments, the distribution of road making material, and so forth, would have to be taken into account.

One such consideration is the possibility of future urban growth which will lead to the places concerned sending out and attracting to themselves a greatly increased volume of traffic; should this occur, the place so developing would need additional market and interurban routes, striking out from it at varying angles, and in some cases cutting diagonally across the present rectangular road-patterns. It is suggested that tentative plans for such diagonal roads be drawn up with regard to certain prominent centres, and some arrangement—such as the prohibition of the erection of buildings in their track—be made to ensure the possibility of their being constructed at the lowest possible cost, if need should arise in the future.

It is the opinion of the commissioners that if due care is taken in studying the situation, the county roads, those taking care of the heavy non-local traffic, need not greatly exceed 15% of the whole. Thus they view the problem as that of bringing 42,500 miles of township roads to a reasonably fair standard, and of fitting 7,500 miles of county roads to bear the severe demands made upon them.

County Roads.—The cost of the county roads is bound to be considerable. Until the advent of the high-speed motor, the art of road-building had been in a fairly settled condition, but the new vehicles had thrown it back into an experimental stage. The problem is rendered the more difficult by the fact that motors and horse-drawn vehicles use the same roadways, with destructive effect; for the narrow tires of heavy wagons grind the stone to dust, and keep the road in a condition in which the shearing effect of rubber tires of the motor is most severely felt. Thus certain types of roads which would withstand motor traffic alone, fail when used by both types of vehicle. The practical effect of this condition is that the cost of roads exposed to heavy traffic is increasing.

The report makes the following recommendations with regard to the treatment of these roads, which are subject to specially heavy traffic:

(1) With regard to suburban roads, the selection of roads to be regarded as such should lie with the province; the various interests affected should, of course, be heard. The control of the construction and the subsequent maintenance should be committed to boards of trustees, on which the city and the county should be represented.

With regard to the financial measures necessary to construct and maintain these special roads, they suggest that the annual support given by the cities should not exceed a rate of three-quarters of a mill. The funds provided by the cities should be expended solely on roads within their own suburban areas. The proportions of cost to be borne by the several parties concerned in these roads should be as follows:

The city	30%
The county	30%
The province	40%

Should the cost exceed $10,000 a mile, the excess should be levied as a local improvement tax.

(2) The treatment of interurban roads may be noticed. Within suburban areas, these roads should be treated as suburban roads. Once outside the suburban belt, the cost of construction might be divided into three equal portions among the province, the county, and the motor vehicles, and as the province is the recipient of motor fees, its proportion might be two-thirds up to a total average cost of $12,000 per mile.

With respect to the distribution of the cost of maintenance, the commissioners recommend that in the case of suburban roads, the city, the county, and the province should each contribute a third. In the case of the interurban roads outside of suburban areas, they recommend that the county contribute sixty per cent. and the province forty per cent.

As regards county rural roads, the control should rest with the county council, or in a permanent commission to be selected by that body. As regards the cost alike to construction and maintenance, the division proposed is sixty per cent. to be borne by the county and forty per cent. by the province.

Township Roads.—An opinion which finds influential backing is that a vast amount of energy is wasted on these roads through the dumping of earth on the roadway to be quickly washed away during the usual wet season. Therefore, these township roads need attention. There are 426 organized townships in the province, with a total assessment in 1912 of $604,737,037. The average rate for roads and bridges of this class is about $1,500,000 annually.

It is held that the control of such roads, and the work of construction and supervision must rest as at present, entirely with local township councils. It nevertheless seems highly important that some assistance should be extended to those townships, as the welfare of the province demands that a heavy percentage of their rural roads should be brought up as quickly as possible to a fair standard as earth roads; and it is felt that to accomplish

this, some provision for stimulating local interest and directing local endeavor along channels in which it will prove most effective should be made.

The new highways organization should be specially charged to give attention to main township roads. Provincial support meanwhile might be limited to three years, when the department would be in a better position to bring forward some plan for rapidly bringing these roads up to meet the business needs of the people.

It is proposed that the aid should not be given to townships until the county has assumed a system of market roads; otherwise, as alternative plans, they might seriously interfere with the installation of a proper system of such county roads. It is felt that provision for a system of good market roads in each county is of first importance and that aid to townships should not be in any way allowed to take the place of such roads. Aided county and township roads are designed to be complementary parts in a general scheme; and aid to local roads should be for the purpose of encouraging their improvement as feeders to the market lines of more general use.

As a tentative plan, it is suggested that the province be prepared to provide $250,000 annually for three years, which is about 20% of two mills on the total assessment of about $604,000,000, or between 15 and 20% of the present cash expenditure by townships on their roads. The apportionment of the aid might be effected in various ways. One would be to make it on basis of population; another would be to make it on the basis of assessment. A third, which would be of special benefit to the weaker municipalities, would be $50,000, $50,000 and $150,000, to be distributed proportionally on a basis of assessment, population and area, respectively.

A plan of assistance which has been suggested is that short-term loans without interest might be granted to townships by the government for road purposes.

In each case the grant should depend upon the observance of certain conditions, such as:

(1) Each township should spend at least $4 on its township roads for every dollar to be contributed by the government.

(2) Proper drainage should be installed for each stretch of roadway aided.

(3) Statute labor should be abolished or commuted.

(4) The roads should be dragged.

(5) A proper township road organization should be established.

The establishment of an efficient organization is vital, and the most essential feature of such an organization is one township foreman in charge of road work displacing all other pathmasters and commissioners and retained as permanently as a township clerk or treasurer.

Little progress can be expected from township expenditure until it is put in charge of permanent road foremen, who, by their growing experience and constant attention, can bring system, uniformity, and continuity into the work.

In addition, therefore, to the actual improvement that would be accomplished by the expenditure suggested, it is felt that the educational value of the methods of road-building upon which the province could insist would be great, and that once the value of such methods could in this practical way be exemplified in a community, there would be little desire to return to the less effective methods at present generally in use.

With respect to the taxation of motor vehicles the commissioners recommended the following scheme:

(1) Automobiles:	
Horse-power (brake)	Registration fee.
Up to 20	$10.00 per car
21 to 30	50 per h.p.
31 to 40	60 per h.p.
41 to 56	75 per h.p.
Over 56	1.00 per h.p.
(2) Commercial Trucks:	
2 tons and less	10.00 per car
Over 2 tons	5.00 per ton
(3) Motor cycles	4.00
(4) Chauffeurs	4.00
(5) Foreign tourists	10.00 (uniformly)
(6) Foreign trucks	10.00 (uniformly)

The above figures applied to Ontario motors, etc., would yield about	$400,000
New York fees applied to Ontario motors would yield about	101,340
New Hampshire fees applied to Ontario motors would yield about	658,115
Great Britain fees applied to Ontario motors would yield about	658,115
Italy fees applied to Ontario motors would yield about	844,129

It is understood that the New York fees may be increased.

In proposing these rates of taxation, the commissioners decline to take the view that the motor tax should be levied as a punitive measure, on the ground that these machines are the chief agency in the destruction of the roads. For one reason, horse-drawn vehicles also use the roads, and in some cases contribute the sort of wear which causes the motors to be destructive; there are certain types of roads which would give fair satisfaction if their use was confined to motors, but which deteriorate rapidly when the narrow-tyred wagon abrades their surface in such a way as to give the clutching wheel of the motor car the excavating effect which the road-builders dread. For another, if the principle of grading the taxation, according to the individual's use of the roads were accepted, it might be urged that the contributors of taxes to the upkeep of schools should be those whose children attend, and those alone; and on a per capita basis, regardless of the varying ability of the taxpayers to contribute.

Summary of Recommendations.—The recommendations of the commission may be briefly summarized as follows:—

1. The committing of the actual control and management of the roads, so far as possible, to local bodies—the county councils, or commissions appointed by them, boards of trustees, etc.

2. The blocking out of a definite amount of work to be begun in 1915, and to be completed about 1930. Cities should contribute at least to the construction and upkeep of the roads in their immediate neighborhood. The permanent construction work should be regarded as a capital expenditure, and should be financed by bond issues designed to reach by 1930 a total sum of about $30,000,000, apportioned as follows:

To the province (including the capitalization of some of the revenue from motor fees)	$12,000,000
To the counties	12,000,000
To the cities	6,000,000

3. The provision for proper maintenance for every mile of permanent road work, the funds for this to be obtained from current revenues.

4. The devoting of special attention to the improvement of township roads.

5. The putting of taxation of motor vehicles on a systematic basis, which your commission estimate would produce about $400,000 in the earlier years.

The development of a central highways department under the headship of a minister of the Crown, with its permanent principal officials, a deputy minister and a chief engineer, and in addition an unpaid advisory commission of men with a genius for accomplishing big things.

Work on County Roads During 1914.—In view of the impossibility of installing a new plan of road development as outlined in the report before 1915, the commission advises that:

1. Counties now operating under the Highway Act should be encouraged to continue as usual their road work this coming summer, and that the regulations under the Act should be made as elastic as possible so as to allow the other counties to begin work and thereby take advantage of the aid thereunder.

2. There should be created a sufficient organization to carry on this summer the following investigations:

(*a*) A motor survey of principal roads to determine their physical condition.

(*b*) A traffic census to determine the present road needs of the province.

(*c*) An investigation of main township road conditions.

(*d*) An investigation of the Hamilton-Toronto, and Ottawa-St. Lawrence roads, obtaining plans and specifications of same.

(*e*) An investigation designed to outline a plan of market roads for counties not now operating under the Highway Act.

(*f*) A determination of suburban areas about principal centres.

COST OF COMPLETION OF C.N.R.

In regard to the proposed bond guarantee of $45,000,000 to the Canadian Northern Railway, the following engineers' estimate of the amount necessary for the completion of the system is given:—

	Required for construction.	For betterments.
Canadian Northern Pacific	$23,647,402	....
Canadian Northern Alberta	542,959	....
Canadian North-Western	310,088	$ 45,000
Canadian Northern Railway	5,402,712	8,005,000
Canadian Northern Saskatchewan	457,849	....
Canadian Northern Ontario	11,645,467	830,000
Irondale, Bancroft	....	....
Central Ontario	....	....
Bay of Quinte	....	....
Brockville and Westport	....	....
Canadian Northern Quebec	....	870,000
Quebec, Lake St. John	....	175,000
Halifax and S.W.	....	....
Duluth, Winnipeg Pacific	....	....
Total construction	$41,987,465	$10,000,000

The statement shows in addition sub-contractors' accounts not included in the above amounting to $8,348,290 in Western lines, and $6,606,424 in Eastern lines. The estimate of rolling stock required is placed at $27,441,086, plus $10,000,000 for betterments, making a total under these three heads of $100,379,099.

Against this amount there is a sum of $58,473,982, being proceeds of securities earned or available, leaving a balance of $41,905,117.

THE PAVING OUTLOOK FOR 1914.

ALTHOUGH many cities have not set out upon a definite plan of paving operations for the present season, *The Canadian Engineer* has received from a number of them an approximate estimate of the work under contemplation. The figures thus derived are presented herewith, the quantities in each case being given in square yards:—

Belleville, Ont.—Concrete, 18,000; gravel, 10,000; macadam, 25,000.

Berlin, Ont.—Bitulithic, 1,300; bituminous macadam, 22,000; treated wood block, 21,000.

Brandon, Man.—Asphalt block, 20,000; bituminous macadam, 14,000; the former to be contract work, the latter, city day labor.

Brantford, Ont.—Bituminous macadam, 10,000; gravel, 25,000.

Charlottetown, P.E.I.—Macadam, 10,600.

Guelph, Ont.—Bituminous macadam (contract work), 30,000; macadam with tar binder (city day labor), 25,000.

Halifax, N.S.—Bitulithic, or sheet asphalt, 20,000; granite block, 10,000; the latter, city day labor, the former, contract work.

Hamilton, Ont.—Asphaltic concrete, 15,000; bituminous macadam, 10,000; vitrified brick, 4,000; granite block, 1,000; macadam (not bituminous) 200,000; sheet asphalt, 100,000; treated wood block, 20,000; all to be laid by day labor.

Hull, Que.—Asphaltic concrete, 25,000.

Lethbridge, Alta.—Subway and approaches only, 4,300 sq. yds., probably concrete under contract.

London, Ont.—Asphaltic concrete or sheet asphalt, 50,000; vitrified brick, 10,000; concrete, 10,000; gravel, 10,000.

Moncton, N.B.—Bituminous macadam, 20,000; macadam (not bituminous), 15,000.

Montreal, Que.—Bitulithic, 86,000; bituminous macadam, 128,600; sheet asphalt, 300,000; Scoria block, 95,000; stone block, 63,000; treated wood block, 13,200.

New Westminster, B.C.—Asphaltic concrete, 19,200; bitulithic, 23,400.

Niagara Falls, Ont.—Vitrified brick, 62,000; concrete, 12,000, (in both cases city will provide materials but work may be done by contract on percentage basis); macadam (not bituminous), 12,000, to be done by city day labor.

North Vancouver, B.C.—Ordinary macadam, 25,000, to be laid by city.

Ottawa, Ont.—Bituminous macadam, 8,000; sheet asphalt, 100,000; treated wood block, 4,000. The macadam to be laid by city, the remainder under contract.

Peterborough, Ont.—Asphaltic concrete, 35,000; vitrified brick, 11,000; all to be contract work.

Prince Rupert, B.C.—Waterbound macadam, 30,000; plank road, 36,000. The city will lay the former.

St. John, N.B.—Bituminous macadam, 8,000; granite block, 6,000.

Saskatoon, Sask.—Bitulithic, 4,800; stone block, 800; treated wood block, 6,000; all to be contract work.

Sherbrooke, Que. — Ordinary macadam, 10,000; granite or treated wood block, 9,000.

Stratford, Ont.—Asphaltic concrete, 2,000; bituminous macadam, 11,000; vitrified brick, 6,500; concrete,

5,800; all of which, with the possible exception of some of the concrete, will be laid under contract.

Toronto, Ont.—Bitulithic, 78,000; bituminous macadam, 82,000; vitrified brick, 31,700; concrete, 28,000; sheet asphalt, 454,000; treated wood block, 31,000. Tenders will be called on all of this work, the Department of Works submitting a tender as well.

Vancouver, B.C.—Asphaltic concrete, 77,000; bitulithic, 32,500; vitrified brick, 13,500; sheet asphalt, 1,350; treated wood block, 3,000, with the following in track allowance: granite block, 1,800; concrete, 1,825; granitoid, 10,850. All of the pavement will be laid as contract work.

Victoria, B.C.—Sheet asphalt, 95,000. Grading, curb, gutter, and concrete base will be laid by city day labor, and asphalt surfacing by contract.

Westmount, Que.—Bituminous macadam, 900 (city); concrete, 4,800 (city); granite block, 5,500 (contract); sheet asphalt, 20,500 (contract); Scoria block, 3,400 (contract); tar painted macadam, 250 (city).

Winnipeg, Man.—Sheet asphalt, 100,000.

Woodstock, Ont.—Concrete, 1,250; waterbound macadam, 10,500; the former, contract work, the latter by city day labor.

Among the cities whose plans have not been settled might be mentioned Edmonton, whose commissioners have under consideration tenders for 275,000 square yards of street and lane paving with curb and gutter. Moose Jaw is contemplating laying about 20,000 sq. yds. of pavement this year, the type to be chosen subject to bids. Regina proposes to shortly call for tenders for paving, also. Sydney, N.S., is not seriously considering any street paving at present. In 1912 a sum of $100,000 was voted for paving two streets, but the difficulty experienced in the disposal of bonds has delayed the work. No particular type of pavement has been decided upon. It is probable that Medicine Hat, Alta., will lay some permanent pavement this year, but the type or types have not been chosen, nor the quantities fixed. Among the cities that have decided upon no paving program up to the time of writing are Chatham, Ont.; Nelson, B.C.; Port Arthur, Ont.; Portage la Prairie, Man.; Prince Albert, Sask.; Quebec, and St. Hyacinthe, Que.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

On April 30th the mechanical section of the Canadian Society of Civil Engineers was addressed in Montreal by Mr. L. C. Ord, on the Steel Car Shops at Angus. The paper was a splendid description of the shops of the C.P.R. for the construction of steel passenger and freight cars. The design and layout of the freight shop with its 41,785 sq. ft. of floor area, including machine shop, assembling and erecting shops, was dealt with in detail, this section of the plant having been designed chiefly for the construction of steel-frame box cars. The passenger shop was also described, many features of it being similar to those of the freight shop, such, for instance, as the method of handling material, arrangement of machinery and its operation.

The meeting was the closing one of the session.

The statement was made in Winnipeg recently by the president of the Lake of the Woods Milling Company, Colonel Meighen, that that company will spend large sums in Western Canada this year increasing its plant.

Coast to Coast

Guelph, Ont.—The bridge at Guelph from Riverside Park to Wellington Place has been formally opened.

Windsor, Ont.—An offer of Windsor of $155,000 for the Sandwich, Windsor, and Amherstburg railway was refused.

Caron, Alta.—Two more dams for the conservation of water on the west side of the pumping station at Caron, Alta., have been completed.

Toronto, Ont.—The earnings so far for 1914 of the Toronto Street Railway company have amounted to $1,975,304, the earnings for April being $501,435. This means that the company's business is growing at present at a rate of 5.5 per cent. annually.

Niagara Falls, Ont.—A statement of combined gross earnings for the Niagara Falls Power Company and the Canadian Niagara Power Company for the year ending December 31st, 1913, has been given as $2,742,192, an increase of $254,996 over 1912. After deducting 19.70 per cent. of gross for operating expenses, and the various amounts for interest on mortgage bonds, etc., and after adding amounts for other income of the company, the surplus income for 1913 was $1,070,100, compared with $927,857 for 1912.

Medicine Hat, Alta.—The report of the city engineer of Medicine Hat for the month of April showed that the gas system was extended 1,500 feet in the high-pressure mains; the water distribution system, 3,883 feet by means of 6-inch pipe; while domestic sewers were installed amounting to 9,463 lineal feet; and storm sewers, to the extent of 2,837 feet. Also during the month 91,134 square feet of cement sidewalk were laid, making a total of about 3 miles of 6-foot walks; also about 2,250 square feet of street crossings and 432 square feet of lane crossings. The electric light line was extended 9,974 feet, the roadway under the subway in Altawana was widened by placing 37 piles on the edge, the bridge over Ross Creek was refloored, and a number of improvements were made to the various parks of the city.

Victoria, B.C.—Railway construction reports from Victoria show progress on all railroads. Plans have been perfected for commencing grading on the P.G.E. railway between Clinton and Fort George, and the company is also busy arranging for the construction of the road from Fort George to the Peace River country. On the main line of the C.N.P. railway, it is reported that grading will be completed from the Rockies to the coast in June. The building of the Cisco bridge is so far advanced that its completion is promised within a fortnight. Immediately this work is done track-laying will be carried on to Kamloops. As far as this point most of the bridges are in place; and, from Kamloops to the North Thompson, 120 miles of steel is being laid; while the ballasting of the road is being carried on simultaneously with the tracklaying. On the Kettle Valley railway, on the joint section of the Hope Mountain route, more than half of the grading work is complete. With the exception of a 3-mile stretch, grading work is now proceeding on the entire 38-mile section between Hope and Coquahalla Summit, the portion of the Hope Mountain route which is to be used jointly by the V.V. and E. railway and the K.V.R. Also grading is proceeding on the last link of the Kettle Valley railway, which will afford connection with the V.V. and E. at Princeton; and nearly two-thirds of the grading has been completed on the 27-mile section of the latter line between Princeton and Otter Summit. While, north-west of Princeton on the V.V. and E. railway, it is expected that grading will be finished and that tracklaying will commence by the middle of August, and that the section will be ready for traffic late this autumn.

PERSONALS.

ROBT. J. MARSHALL, B.A.Sc., has recently been appointed town engineer of Trenton, Ont

FRANK BARBER, bridge and structural engineer, Toronto, has been retained by the township of Etobicoke as township engineer.

H. B. PEARSON, manager of the Calgary Heat and Light Company, has received the appointment of consulting gas engineer to the city of Calgary.

GEORGE KIDD has been appointed general manager of the British Columbia Electric Railway Company, Vancouver, to succeed R. H. Sperling, resigned.

W. W. PEARSE, formerly of New York, has been chosen by the City of Toronto for the position of city architect, his duties to commence May 18th. Mr. Pearse has spent 20 years in architectural work.

CHAS. G. TOMS, B.A.Sc., has been appointed general manager of the Toms Contracting Company, Limited, Toronto. Mr. Toms is a graduate in civil engineering of the University of Toronto, and took a post-graduate course in

Chas. G. Toms, B.A.Sc.

structural engineering. He has acquired considerable experience in construction work of various kinds, chiefly in concrete and building construction.

J. A. BOYLE, until recently on the construction engineering staff of the C.N.R. at Winnipeg, has been appointed engineer in charge of the construction of the Winnipeg River Railway, a part of the Greater Winnipeg Water District scheme.

GARNET B. HUGHES, son of Hon. Col. Sam. Hughes, has been appointed resident engineer on Vancouver Island for the Department of Public Works. Mr. J. F. McLachlan, who formerly occupied the position, is in charge of the Victoria harbor development.

W. MAXWELL, mine manager of the Lethbridge Collieries, has been appointed government mine inspector for the Crow's Nest Pass district to succeed A. N. Scott, who has accepted the position of manager of the Jasper Park Collieries, west of Edmonton.

LEONARD ANDREWS, M. Inst. C.E., M.I.C.E., managing director of the Canadian British Engineering Company, Limited, has arrived in Winnipeg from England, and will take charge of the Canadian management of his firm. Reginald Porter, who has been the Canadian manager for the past year, has returned to England to resume his previous duties as manager of the London office.

OBITUARY.

The death occurred in Victoria recently of J. M. Sutton, a prominent geologist. Mr. Sutton was a noted authority on the resources of Vancouver Island.

The death occurred last week of A. B. Willmott, B.A., B.Sc., a Toronto consulting mining engineer. Mr. Willmott was a graduate of the University of Toronto, and he also took a post-graduate course at Harvard. Prior to his consulting practice he was manager of mines for the Clergue interests, before the organization of the present Lake Superior Corporation. Previous to that he was associated with academic work, having held a professorship at McMaster University, Toronto, and Antioch College, Ohio. The late Mr. Willmott was in his 48th year.

The death is reported from Brockville, Ont., of John G. Steacy, railway contractor, at the age of 77. Deceased had been associated with many prominent railway construction enterprises in America and abroad. In Canada he built the first 50 miles of the European and North American Railway, from St. John, N.B. He was also associated with the erection of the passenger stations and engine shops of the G.T.R.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11th to 15th, 1914. Secretary, J. M. Diven, 47 State Street, Troy, N.Y.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

INTERNATIONAL CONFERENCE ON CITY PLANNING.—To be held in Toronto, May 25th, 26th and 27th, 1914, in charge of the Commission of Conservation. Secretary, James White, Ottawa.

AMERICAN SOCIETY FOR TESTING MATERIALS. —Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30th to July 4th, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Summer convention to be held at Brighton Beach, N.Y., July 3rd and 4th, 1914. Secretary, J. R. Wemlinger, 11 Broadway, New York.

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal.

AMERICAN PEAT SOCIETY.—Eighth Annual Meeting will be held in Duluth, Minn., on August 20th, 21st and 22nd, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

CANADIAN FORESTRY ASSOCIATION.—Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal.

CONVENTION OF THE AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—To be held in Boston, Mass., on October 6th, 7th, 8th and 9th, 1914. C. C. Brown, Indianapolis, Ind., Secretary.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9th to 13th, 1914. I. S. Pennybacker, Executive Secretary, and Chas. P. Light, Business Manager, Colorado Building, Washington, D.C.

ORDERS OF THE RAILWAY COMMISSIONERS
OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21702—April 29—Authorizing C.N.R. to construct across 23 highways in Province of Saskatchewan.

21703—April 29—Authorizing C.P.R. to reconstruct 2 bridges in Province of Manitoba, namely,—No. 7.6, Emerson Sub. Div., Man. Div., and No. 8.4, Winnipeg Branch Sub. Div., Man. Div.

21704—April 29—Authorizing C.P.R. to reconstruct bridge No. 11.9 on Brandon Sub. Div., Man. Div., Manitoba.

21705—April 28—Authorizing C.P.R. to construct tracks of spur to ballast pit across highway between Secs. 22 and 27-18-17, W. 3 M., Sask., mileage 23.79 on Swift Current North-westerly Branch Line.

21706—April 21—Approving and authorizing, temporarily, clearances as shown on plan under File No. 23749, subject to condition that C.P.R. undertake to keep employees off sides of cars while shunting on tracks Nos. 17, 18, and 19, in West Toronto Yard, and pending rearrangement by Ry. Co., of switching lead to provide standard 13-foot clearances between centres of all tracks.

21707—April 25—Authorizing C.N.R. to construct, subject to terms of agreement, spur to gravel deposit, N.W. ¼ Sec 8-15-1, W.P.M., for Lake Winnipeg Shipping Co., and cross certain highways.

21708—April 29—Authorizing C.P.R. to construct spur for Canada Cement Co., Limited, Montreal, Que., from point in easterly limit of right of way of main line, mileage 7.1, La Riviere Subdivision, Man. Div., across lands of Huebach and Co.; across road allowance and Lots 1, 2 and 3, Parcel B, parish of St. Charles, Man.

21709—April 29—Authorizing C.P.R. to construct spur for Calgary Paint and Glass Co., Limited, Calgary, Alta., subject to and upon certain conditions.

21710—April 29—Approving By-Law No. 15, authorizing G.T.P. Ry., to appoint G. T. Bell, Pass. Traffic Mgr., W. P. Hinton, Assist. Pass. Traffic Mgr., and W. E. Duperow, Assist. General Pass. Agt., to prepare and issue, from time to time, tariffs of tolls to be charged for passenger traffic upon railway owned or operated by Co., or any portion thereof, and to specify the persons to whom, place where and manner in which such tolls shall be paid; and rescinding Order No. 8288, dated October 8th, 1909.

21711—April 28—Directing G.T.R. to install gates, operated by day and night watchmen, at crossing by its tracks of Eighteenth Ave., city of Lachine, and apportioning cost of installing, maintaining and operating said gates; also rescinding Order No. 9616, dated February 7th, 1910, directing installation of an electric bell at said crossing.

21712—April 29—Authorizing C.N.O.R. to construct across Weston Plank Road, city of Toronto, by means of structure carrying highway over railway.

21713—April 29—Authorizing Pointe aux Trembles Terminal Ry., to construct across Montreal Terminal Ry. in parish of Pointe aux Trembles, Que., subject to certain conditions.

21714—April 29—Authorizing C.P.R. to construct, at grade, an additional track (double track) of main line, Farnham Subdivision across Champlain St., town of St. Johns, Que., mileage 19.9, temporarily, pending hearing of matter at sittings of Board to be held in Montreal, May 15th, 1914.

21715—April 30—Approving location C.P.R. platform and shelter, at mileage 9.20 on Bobcaygeon Subdivision, Ont. Division, in Lot 20, Con. 9, Tp. Cartwright, Co. Durham, Ontario.

21716—April 30—Dismissing complaint of R. L. Rice of Vancouver, B.C., against charge made by C.P.R. for 2 seats in a sleeping car for daylight journey from Sicamous, B.C., to Vancouver.

21717—April 30—Authorizing C.N.R. to operate trains, temporarily, for construction purposes only, for period of 90 days from date of this Order, pending installation of interlocking plant, over crossing of C.P.R., Lot 101, parish of St. Paul, Man.: provided trains be flagged over crossing by watchmen, appointed by C.P.R., at expense of C.N.R. and rescinding Order No. 21617, dated April 9, 1914.

21718—April 30—Approving By-Law of G.T.R. appointing certain men to prepare and issue tariffs of tolls for passenger traffic on railway owned or operated by Co., or any portion thereof; and rescinding Order No. 13449, dated April 18th, 1911.

21719—April 28—Relieving G.T.R. from providing further protection at crossing of highway known as Danforth Road, east of Scarboro Junction, Ontario.

21720—April 30—Authorizing G.T.R., to construct siding into premises of William R. Smith, on part Lot 7, Con. 1, from Bay, in Tp. York, now in city of Toronto.

21721—May 1—Amending Order No. 4353, dated February 3rd, 1908, by striking out last paragraph in operative part of Order and substituting following:—"That Pacific Co. repay or refund to Campbell, Wilson and Horne, Limited, by way of rebate, ½ tolls charged by Pacific Co., in respect of carriage of traffic for said Campbell, Wilson and Horne, Limited, Geo. R. Marnoch, and the Western Supply and Equipment Co., over said branch line or spur."

21722—April 27—Authorizing C.P.R. to take certain tract of land in parish of St. Martin, Co. Laval, Que., for purpose of enlarging station yard at Laval Rapids.

21723—May 1—Approving C.P.R. plan "A," showing proposed rearrangement of interlocking plant at crossing of Q.M. and S. at Iberville Jct., Quebec.

21724—April 28—Approving C.P.R. plan dated Brandon, April, 1914, and showing layout of crossing bell at First Ave., Oak Lake, Man.; and relieving Company from speed limitation of 10 miles an hour in operation of trains over said crossing.

21725—April 29—Authorizing C.L.O. and W. Ry. (C.P.R.) to construct across unopened road allowance between Lots 4 and 5, mileage 88.62, Con. 1, Tp. Murray, East Riding, Co. Northumberland, Ontario.

21726—April 22—Authorizing G.T.R. to construct siding into premises of S. W. Marchmont, on Lot 47, Tp. Niagara, Co. Lincoln, Ont., near St. Davids.

21727—April 27—Authorizing Cedars Rapids Manufacturing and Power Company of Montreal to take additional width for right of way for its transmission line across Lot 122, parish of St. Ignace du Coteau du Lac, property of Rev. Chanoine Dauth.

21728—April 29—Authorizing Marcil Trust Co., Limited, to relocate farm crossing on Official Lot 61, parish of Pointe Claire, west of Strathmore Station, Que., to point about 75 ft. easterly from present location, work to be done under supervision of Engineer of G.T.R. Co.

21729—April 22—Authorizing C.N.R. to cross abandoned right-of-way of C.P.R. in town of East Selkirk, Man.; and reserving question of seniority and protection until such time as C.P.R. desire to lay tracks in right-of-way at this point.

21730—April 29—Authorizing C.N.O.R. to construct across Silverthorne Ave., Toronto, by means of structure carrying highway over railway.

21731—May 1—Authorizing G.T.P. Ry. to construct ladder tracks across Kinistino Ave., Edmonton, Alta.; and approving station for freight with accommodation and facilities in connection therewith, subject to certain conditions.

21732—May 1—Authorizing Cedars Rapids Manufacturing and Power Co., Montreal, to take additional width of 25 ft for right of way for transmission line, across certain lots, parish of St. Ignace du Coteau du Lac, Co. Soulanges, Que.

21733—May [illegible]—Amending Order No. 21480, March 13th, 1914, by striking out words and figures, "at mileage 1.11 (spur mileage), town of Trenton, Ont., as shown on plan, profile and book of reference combined," in lines 5, 6 and 7, paragraph 1 of operative part of Order, and substituting words and figures, "at mileage 1.43, town of Trenton, as shown in yellow down to point near intersection of Ann and Ontario St., and in red from that point to point near Dundas St., at mileage 1.43 on plan, profile and book of reference combined."

21734—May 2—Directing that G.N.W. Tel. Co. remove its wires and poles from Kent and certain other streets in town of Lindsay, Ont., subject to certain conditions. That G.N.W. Tel Co., pay expense of making necessary connections as set out in clauses (a), (b) and (c) herein; cost of remainder of work be paid $150 by G.N.W. Tel Co., balance by Applicant (town of Lindsay).

21735—May 1—Directing that C.N.R. erect fences along right of way (Ottawa-Capreol Line) through Twps. Field, Crerar, Badgerow and Gibbons, Dist. Sudbury, Ont., within 60 days from date of this Order.

21736—May 1—Authorizing C P.R. to construct spur into premises of National Cash Register Co., situate in Tp. Lot 27, Con. 2, from the Bay, in Tp. York, Co. York, Ontario, subject to certain conditions.

21737—May 2—Authorizing G.T.P. Branch Lines Co. to carry traffic over portion of Young to Prince Albert Branch Line, Sask., between mileage 67 (Wakaw) and 87: Provided speed of trains operated over said portion be limited to rate not exceeding 15 miles an hour.

21738—May 2—Authorizing C.P.R. to reconstruct Bridge No. 5.3 on Walkerton Subdivision, Ont. Division, near Priceville Station, Ontario.

21739—May 2—Authorizing C.N.R. and C.P.R. to operate trains over crossing in Sec. 35-24-27, W. 4 M., Alta., without their being brought to a stop.

21740—May 4—Amending Order 21481, March 13th, 1914, by striking out figures and word "0.47 and 0.74" in 5th line of operative part of Order and substituting therefor figures and word "0.55 and 1.05"; and by striking out words and figures "October 2, 1913" in 6th line of operative part of Order and substituting words and figures "November 25, 1913."

21741—May 2—Approving Lake Erie and Northern Ry. Co.'s plan of overhead bridge at crossing of highway between Cons. 2 and 3, Tp. Brantford, Ont., mileage 16.92.

21742—May 2—Authorizing T.H. and B. and Hamilton St. Ry. Co. to operate their trains and cars over crossing on Barton St., City of Hamilton, without being brought to a stop.

21743—April 20—Approving Bell Telephone Co. agreement entered in with Municipal Corporation of Tp. of Brighton, dated March 31st, 1914, for interchange of telephone messages or service passing to or from their respective telephone systems and lines.

21744—May 2—Authorizing G.T.P. Ry. to construct main line across and divert highway in Lot 935, Cariboo Dist., B.C., mileage 232.3 Yellowhead Pass West.

21745—May 2—Directing that classification of maple butter be made the same as classification of peanut butter, the change to be included in Supplement No. 3 to Canadian Freight Classification No. 16.

21746—May 4—Disallowing Supplement No. 146 to G.T.R. Special Tariff, C.R.C. No. E-2552, increasing rate on clay, in carloads, from Waterdown to Swansea and Mimico, Ont., from 1½ cts. per 100 lbs. to 2 cts. per 100 lbs., and the rate of 1½ cts. per 100 lbs. is restored.

21747—May 4—Authorizing Cedars Rapids Manufacturing and Power Co. of Montreal, to take additional land for right of way for its transmission line, across certain lots in parish of St. Joseph de Soulanges, Co. Soulanges, Que., property of Adolphe Tessier, Maurice Tessier and Maurice Tessier and Adolphe Tessier.

21748—May 2—Authorizing Rural Municipality of Usborne No. 310, Sask., to construct crossing over C.P.R. Pheasant Hills Branch at West Boundary of S.E. ¼ Sec. 34-33-23, W. 2 M., Sask.; and rescinding Order No. 21452, dated March 9, 1914.

21765—May 6—Approving Supplement No. 4 to Express Classification for Canada No. 3, containing changes with respect to carriage of moving picture films, organs, pianos [illegible] player [illegible].

21766—May 6—Authorizing T.H. and B. Ry. to divert highway between Lots 21 and 22, Con. 5, Tp. Gainsboro, Co. Lincoln, Ont.; also authorizing Ry. Co. to acquire from owner thereof a 66-ft. parcel of land connecting said highway between Lots 21 and 22, Con. 5, Tp. Gainsboro, with highway between Cons. 5 and 6, and to convey to Tp. Gainsboro said 66-ft. parcel, for highway purposes, in lieu of parcel colored yellow on plan.

General Order, No. 124—April 30—Approving regulations to govern operation by railway companies within legislative authority of Parliament of Canada, of draw, or swing, or bascule bridges over navigable waters.

21767—May 5—Authorizing T.H. and B. Ry. to install automatic block signals on its railway between Welland and Hamilton, Ont.; and approving plans of said signals. And rescinding Orders Nos. 14066 and 15974, dated respectively June 24th, 1911, and February 14th, 1912.

21768—May 6—Authorizing C.P.R. to construct spur for Pilkington Brothers, Limited, in city of Calgary, Alta.

21769—May 6—Authorizing C.P.R. to open for traffic portion of double track from mileage 109.4 to 110.5 on Swift Current Subdivision.

21770—May 6—Authorizing C.P.R. to take certain lands in city of Peterboro, Ont., for purpose of providing team road to its freight yard in said city.

21771—May 6—Authorizing C.P.R. to construct extension to siding for William Neilson, Limited, Toronto, Ont., across Zorra St. and along and across Durham St., village of Beachville.

21772—May 7—Authorizing C.P.R. to open for traffic portions of Bergen Northeasterly Line, double track, from mileage 0 to 9.92; Emerson Subdivision, second track, mileage 0 to 2.03; and Lac du Bonnet Subdivision from Whittier, mileage 65.1 to Murdock, mileage 62.2—all in Province of Manitoba.

21773—May 6—Authorizing C.P.R. to construct spur into premises of F. Sask and Co., Limited, and The Constructors, Limited, in city of Regina, Sask.

21774—May 7—Approving plan No. X-2-317/6, dated April 7th, 1914, showing interlocking plant proposed to be installed at crossing of Owen Sound Section of C.P.R. by G.T.R. at Weston Road, town of Toronto Junction, Ontario.

21775—May 7—Authorizing C.P.R. to construct spur for Brunelle and Besner, Vaudreuil, Que., from point on southerly limit of right of way of C.P.R. at mileage 19.47, Smith's Falls Subdivision, Lot Cadastral No. 458, parish of St. Michel de Vaudreuil, Co. Vaudreuil, Que.

21776—May 7—Authorizing C.P.R. to construct spur for Canadian Sewer Pipe and Clay Product Co., Limited, Hamilton, Ont., across lands belonging to Tp. West Flamboro in shape of an unopened road allowance between Cons. 1 and 2, Tp. West Flamboro, Co. Wentworth, Ont., at mileage 1.0 on Hamilton and Goderich Subdivision.

21777—May 2—Approving terms of contract entered between Byron Telephone Co., Limited and Bell Telephone Co. of Canada.

COL. RUTTAN'S RETIREMENT.

It has been announced that Col. H. N. Ruttan, for many years city engineer of Winnipeg, will be relieved of his duties on June 1st next. Col. Ruttan's resignation has not been entirely unexpected. In fact, it was intimated last year that he contemplated resigning at an early date. The untimely death of R. D. Willson, assistant city engineer, delayed the matter, however, and he was induced to continue in office until the disorganization which the fatality had produced would be remedied.

Col. Ruttan is not completely severing his connection with the city. It is understood that he will be retained as consulting engineer at a salary approximating that which he has been receiving as city engineer.

Operations are now proceeding at the Cape Town docks, South Africa, for the erection of 3 huge steel tanks for the storage of oil. The tanks will each contain 4,000 tons of oil, and the total capacity of the three will be 2,688,000 gallons of liquid fuel. The oil will be delivered to ships by means of 10-inch steel piping laid beneath the quay surface, and will also be available for manufacturing and other purposes.

NEW INCORPORATIONS.

Vancouver, B.C.—McIntyre Lumber Co., Limited, $10,000.

Frank, Alta.—Franco-Canadian Collieries, Limited, $1,300,000.

Drumheller, Alta.—Alberta Block Coal Co., Limited, $300,000.

Victoria, B.C.—V. I. Contractors Supply Company, Limited, $10,000.

Maryfield, Sask.—Village of Maryfield Telephone Co., Limited, $2,500.

Nelson, B.C.—Kootenay Granite and Monumental Company, Limited, $50,000.

Grand Forks, B.C.—The Grand Forks Concrete Company, Limited, $10,000.

Medicine Hat, Alta.—Frank H. Gheen, Jr., Gas and Oil Co., Limited, $200,000.

Fort George, B.C.—Northern Interior Light and Power Company, Limited, $50,000.

Hamilton, Ont.—Pay Ore Mines, Limited, $500,000. J. M. Fletcher, B. O. Johnson, E. Farr.

Ottawa, Ont.—Coal Trestle Co., Limited, $300,000. L. A. Ray, G. P. Murphy, R. T. Holcomb.

Calgary, Alta.—Summit Engineering Co., Limited, $50,000. J. H. Goodwin, Limited, $300,000.

Milton, Ont.—Bowlby Sand, Lime, Brick Co., Limited, $100,000. R. Bowlby, R. Boyd, W. I. Dick.

Montreal, Que.—Federal Paper Co., Limited, $100,000. J. J. Meagher, H. N. Chauvin, P. W. Peacock.

Gowganda, Ont.—Gowganda Power Co., Limited, $100,000. J. G. Shaw, J. Montgomery, H. P. Edge.

Seven Islands, Que.—Wynros Navigation Co., Limited, $99,000. G. M. Ross, A. H. Ross, C. E. Ross.

Lancaster, Ont.—The Lancaster Water Works, Limited, $20,000. J. A. Bourbeau, A. Powell, T. Aubry.

Canfield, Ont.—The Azoff Natural Gas Co., Limited, $40,000. H. R. Laird, W. Thompson, A. Moodie.

Valleyfield, Que.—The New Salaberry Quarry Co., Limited, $20,000. J. Dubord, J. Lefebvre, B. Rheaume.

Montreal, Que.—Bernard Construction Co., Limited, $20,000. L. A. Bernard, L. J. Bernard, J. Turcotte.

Windsor, Ont.—General Vending Machines, Limited, $25,000. J. P. Jacques, A. J. Janisse, A. L. Lafferty.

Guelph, Ont.—Munder Tungsten Lamp Company, Limited, $50,000. J. S. Wheeler, J. E. Carter, J. Davidson.

Welland, Ont.—The Corbett Contracting Company, Limited, $100,000. J. H. Corbett, E. Corbett, J. H. Corbett.

Carey, Man.—The Carey Elevator Co., Limited, $20,000. A. Prefontaine, E. Hebert, C. Dandenault, J. F. Lambert.

Parry Sound, Ont.—William Beatty Lands and Timber, Limited, $100,000. E. Beatty, W. J. Beatty, F. I. M. Beatty.

Walkerville, Ont.—Thomas Reinforced Concrete Co., Limited, $50,000. A. Thomas, G. B. Wadham, A. A. Stibbard.

Winnipeg, Man.—The Murray Carbon Remover Co., Limited, $20,000. J. H. G. Russell, A. E. Emby, H. L. Willson.

PATENTS ISSUED.

The following are among the Canadian patents recently issued through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—Toofron Boberg, catalytic hydrogenation of organic substances; George and Leonard Fuller, electrical accumulators or secondary storage batteries; Charles Oliver and Wm. D. Pell, electrodes for flame arc lamps; Charles Caille, processes for superheating steam taken from generators; David Evans, time indicating dials; Herman P. E. Miller, valve mechanism for internal combustion and other engines; George A. Quin, pneumatic tires; Marcus Ruthenberg, electrodes for electric furnaces; Walter W. Smith, building blocks; Henry Watkinson, plastic cement.

Below will be found the list of Canadian patents recently furnished by Messrs. Fetherstonhaugh and Co., patent barristers, solicitors, etc., Toronto, Hamilton, Montreal, Ottawa, Winnipeg, Vancouver and Washington, D.C., from whom all information may be readily obtained:—

W. T. B. McDonald means for stopping trains; P. Ackerman, selective cut outs for alternating current circuits; W. Edwards, safety lock shoes for rails; J. F. Hughes, flushing devices for hydraulic elevators; B. E. Larsen, spring supporters for single blocks; J. A. McLarty, processes of treating organic and inorganic materials; A. E. Quinn, saw combination tools.

TRADE INQUIRIES.

Since the publication of the last Weekly Report there have been received the following inquiries relating to Canadian trade. The names of the firms making these inquiries, with their addresses, can be obtained only by those especially interested in the respective commodities upon application to: "The Inquiries Branch, The Department of Trade and Commerce, Ottawa," or The Secretary of the Canadian Manufacturers' Association. Toronto, or The Secretary of the Board of Trade at London, Toronto, Hamilton, Kingston, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary, Saskatoon, and Chambre de Commerce du Montreal:—

A South American firm inquires for rubber hose. Four South American firms inquire for roofing. A South American firm inquires for aerial cables. South American firms inquire for pumps. A firm in Colombia, South America, inquires for small corundum wheels. A firm in Colombia, South America, inquires for mine supplies. A firm in Colombia, South America, inquires for rails. A firm in Colombia, South America, inquires for steel sleepers. A firm in Colombia, South America, is prepared to handle railway material and rolling stock. Two South American firms inquire for cement. A Colombia, South America, firm inquires for steel bridges. A South American firm inquires for the above. A Japanese company who manufacture asbestos tiles wishes to get into touch with manufacturers and exporters of asbestos fibre in Canada. A British firm in Yokohama wishes to get in touch with reliable exporters of Canadian pulp for paper-making. A London firm asks to be placed in communication with Canadian manufacturers of pemmican. A London firm wishes for the addresses of Canadian firms who can contract to supply birch or maple veneer panelling in large quantities. A prominent importing firm in Hamburg desires to hear from a first-class Canadian house producing or dealing in the above, seeking a representative for Germany and the Continent. Three firms in South America inquire for asbestos roofing. An Englishman carrying on a general commission business in Medellin, Colombia, would be glad to have samples of calcium carbide, both large and small; the former to be 1¼ inches by ⅜ inch, and the latter ¼ inch by ⅛ inch. Quotations c.i.f. Puerto Colombia.

SOME GOVERNMENT CONTRACTS AWARDED RECENTLY.

The following contracts were awarded by the different departments of the Ottawa Government in March, 1914, and are published by the Labor Gazette, together with names and addresses of contractors, and amount of contracts:—Wharf, Shediac Island, N.B. Warren Taylor, Salisbury, N.B., $6,432; breakwater, Caldwell's Cove, N.S. Whidden and Landry, Antigonish, N.S., $6,900; dredging, Sand Heads (mouth of Fraser River), B.C. Navigation Dredging Co., Limited, Vancouver, B.C. Class "B," $0.23½ per cubic yard; renewal of south pier, Burlington Channel, Ont. MacKay, Paulin Construction Co., Limited, Hamilton, Ont.; dredging, Dalhousie, N.B. The Northern Dredging and Construction Co., Limited, Vancouver, B.C. Class "A," $5; Class "B," $0.30 per cubic yard; dredging, Charlottetown, P.E.I. V. T. Bartram, Toronto, Ont. Class "B," $0.28 per cubic yard; wharf, Ste. Anne des Monts, P.Q. John Burns, Ottawa, Ont., $112,000; breakwater, Blanford, N.S. C. A. Strum and Son, Mahone Bay, N.S., $13,721; wharf, Heustis Landing, N.B. Melvin Jones, Cambridge, N.B., $6,275; railway dry dock, Selkirk, Man. The Crandall Engineering Co., Portland, Me., U.S.A., $72,000; roaster building and extension to fuel shed, fuel testing plant, Ottawa, Ont. Taylor and Lackey, Ottawa, Ont., $6,979; wharfs, Victoria Harbor, B.C. Grant, Smith and Co., and McDonnell, Limited, Vancouver, B.C.; wharf, Fitzroy Harbor, Ont. Thos. and John Moran, Arnprior, Ont.; wharf, Thurso, P.Q. Alf. Belanger and Co., Papineauville, P.Q.; wharf, Ainsworth, B.C. J. Dancy and Son, Nelson, B.C., $9,242; pile wharf and approaches, Gananoque, Ont. W. J. Sims, A. Robertson and R. A. Bingham, Ottawa, Ont.; public building, Milverton, Ont. Walter F. Martin, Gananoque, Ont., $24,642; public building, Carman, Man. Snyder Brothers, Portage la Prairie, Man., $29,200; one passenger and three freight elevators in examining warehouse, Calgary, Alta. The Turnbull Elevator Manufacturing Co., Toronto, Ont., $15,950; passenger elevator and motor generator in post office, Moose Jaw, Sask. Otis Fensom Elevator Co., Limited, Toronto, Ont., $5,200. Roofing of St. Gabriel shed No. 1, on the Lachine Canal, Ottawa Street, Montreal; concrete dam across the Rideau River, on the Rideau Canal, Merrickville, Ont. John O'Toose, Ottawa, Ont.; manufactures and erection of a rolling deck steel bridge over the entrance to Basin No. 1, Soulanges Canal, at Cascades Point, P.Q. The Phœnix Bridge and Iron Works, Limited, Montreal, P.Q., $975,000; installation of a telephone train despatching line between Moncton, N.B. and Truro, N.S., on the Intercolonial Railway. The Northern Electric and Manufacturing Co., Limited, $13,974.57; construction and erection of the steel superstructure of five bridges on the Dartmouth to Dean's Branch of the Intercolonial Railway. Dominion Bridge Co., Limited, Montreal, P.Q., $19,748.

IRRIGATION IN AUSTRALIA.

New South Wales has under construction a storage reservoir with a capacity of 33,000,000,000 cu. ft., which constitutes the largest storage scheme in Australia. It is situated on the Murrumbidgee some 300 miles west of Sydney.

The Tri-State Water and Light Association held its fourth annual convention at Atlanta, Ga., having a 2 days' session, commencing April 16, with an attendance of members from Georgia, North and South Carolina. The association discussed such subjects as the purification and treatment of water, the conservation and protection of water supplies and various problems relating to municipal lighting

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

OSHAWA SUB-STATION OF THE ELECTRIC POWER CO.

DESCRIPTION OF THE AUXILIARY POWER PLANT AND SUB-STATION AT OSHAWA, ONT., AND OF THE LARGEST DIESEL OIL ENGINE IN OPERATION IN CANADA.

THE Electric Power Company, Limited, have recently erected and equipped a sub-station and power house in the town of Oshawa, Ont. The power house, to which special reference is made in this article, will be used as a stand-by, to supply light and power to the towns of Oshawa and Whitby in case of trouble or breakdown on the company's high tension transmission lines. The company have an extensive light and power system in the Trent valley, with generating stations at Trenton, Frankfort, Campbellford, Healey Falls, Peterborough and Fenelon Falls. The new Oshawa plant is connected thereto so that it may be immediately thrown into commission to feed back upon the line in case of a shut-down at any point west of Port Hope.

Layout of Building.—The power house and sub-station are housed in an L-shaped building, shown in Fig. 1. The power house is approximately 50 x 52 ft., and the sub-station, containing two rooms, for the switchboards and transformers respectively, measures about 62 x 36 ft. The entire building is of fireproof construction, being of steel framework encased in brick with concrete foundation. It is equipped with steel sash, reinforced concrete floors, and a concrete roof supported by trusses and I-beams. At present the north end of the building is temporarily enclosed, pending an 80-foot future extension.

Power House Arrangement.—A portion of the power house section of the building is shown in Fig. 2. It consists of one large room, to the lighting of which special attention has evidently been paid, steel sash windows extending well towards the ceiling. The room contains one Diesel engine unit of 615 b.h.p., to be described later. The foundations are already in place for a second engine, and provision has been made in the layout for four additional engines, making a complete stand-by station of six units within the building, with all the usual auxiliaries, the yard being laid out for three cooling towers, each tower serving two engines, and six oil tanks of 10,000 gallons each, only one of which is as yet in place.

Fig. 1.—Exterior View of Power House and Sub-station.

Rapid transfer of the oil from tank cars on the power house siding to the main tanks is obtained by a motor-driven centrifugal pump in a small adjacent pump-house. From the main tanks the oil is pumped by a motor-driven rotary pump to two auxiliary tanks, each of 400 gals.

capacity, carried by the roof trusses. From this point the oil is delivered automatically as required to the filter tank adjacent to the engine.

The engine room is equipped with an 8½-ton hand-power crane with a 25-foot lift. The crane has a two-speed hoist and a hand-operated brake, and was supplied by the Whiting Foundry Equipment Co., Harvey, Ill.

The Diesel Engine.—The engine is the largest Diesel engine in Canada, and, as far as we have been able to ascertain, on this continent. It is a 4-cylinder, 615-h.p., Willans-Diesel, designed and constructed by Willans and Robinson, Limited, Rugby, England. It is of the inverted vertical open forced-lubrication type. Its cylinders are single-acting and work on 4-stroke cycle. The normal speed is 180 r.p.m. The engine is guaranteed for a 10% overload for two hours—it was, however, operated for four hours at this overload during the test, carrying its load with ease, and without extra attention.

Some features of the design of this type of engine deserve special mention. The crank-chamber is of the "A" frame type, favored by the makers owing to its adaptability to ready alterations to component parts, everything from the cylinder crown downwards, with the exception of the bed-plate and crank shaft, being identical for engines of from one to four cylinders. It is claimed also that this form permits of easy removal of cylinder, etc.

The cylinder wall is in the form of a tube, which is pressed into the single casting that forms the frame and the water-jacket casing.

The cylinder liner and head are held in position in the framework by studs screwed into the flange formed at the top of the water-jacket casing. These studs, passing through the cylinder head in which is formed the male portion of the tongue and grooved joint, serve also to hold the liner against a shoulder in the flange. Otherwise the liner is free to slide in the two bearings at the centre and base of the jacket casing.

The valves are opened and closed by cams and springs respectively. The cams are keyed on a horizontal shaft driven by an upright shaft and screw gearing from the compressor end of the crank shaft. The exhaust valve levers are in two parts to facilitate the examination of the valves, and the cylinder covers are so designed that the fuel valves are accessible without removing the levers which open them. None of the valves are water-cooled, but the jacket of the exhaust valve casings extend around the valve spindle guides. It is noticeable that the usual order of adjustment on the valve tappets is reversed in this engine. When the valve is on its seating, clearance is to be found between the cam and cam roller, rather than between the valve and operating arm. This is due to the design of the air and exhaust valve levers.

The cam shaft is supported by brackets bolted to the cylinder jacket casting. The bearings are ring-lubricated.

The piston is made of two castings, bolted together. The parts exposed to high temperatures are oil-cooled, by the forced-lubrication system, which is also employed for the crank shaft and connecting rod bearings. A gear pump of drum type, driven by a screw gearing, is located in the base of the engine. Oil is conducted from the main bearings through the drilled crank shaft, and from the crank end to the piston end of the connecting rod by a small pipe and thence to visible discharge cocks. Copious flooding of the cooling chamber in each piston is maintained through trombone tubes by the same oil pump. To prevent destruction of the lubricating qualities of the oil by excessive heating, the system is provided with two tubular coolers arranged in series.

There is one fuel pump, which discharges into a distribution box fitted with four outlet valves, one for each cylinder, adjustable by hand. The governor, which is mounted on the upright shaft between the crank and cam

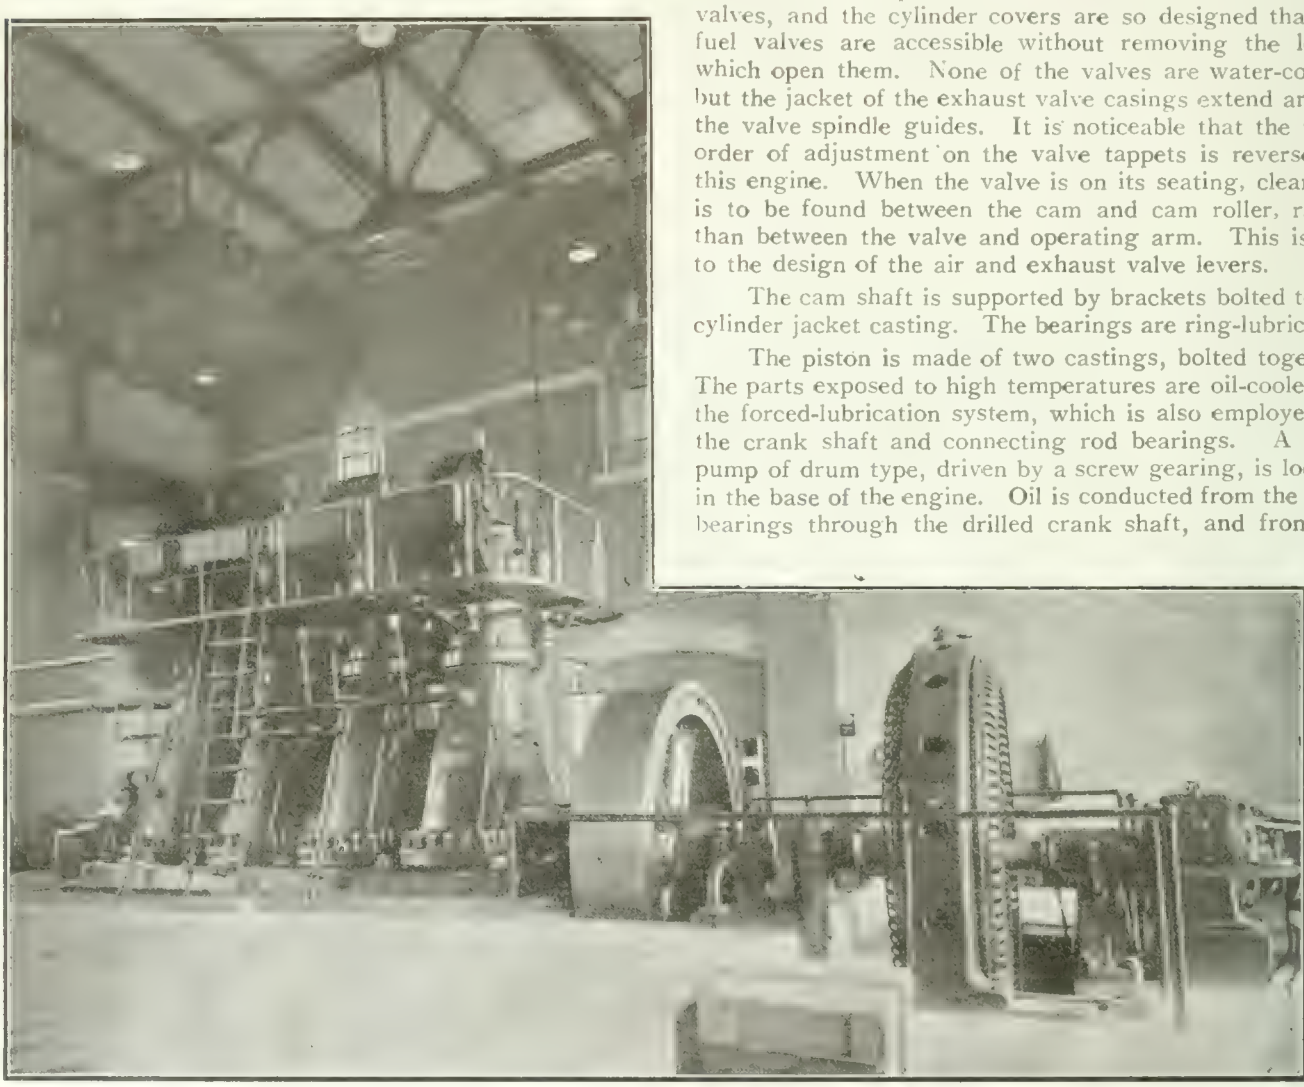

Fig. 2.—Interior of Power House, Showing Willans-Diesel Engine, Generator, Exciter and Suspended Feed Tanks.

shafts, controls the speed of the engine by timing the closing of the suction valve of the fuel pump, so that the actual quantity of fuel oil delivered to the cylinders meets the requirements of the load.

The compressor, for supplying the air required for starting and injection purposes, is a three-stage, quadrupled compressor of the Reavell type. It is driven by an overhung crank bolted to a flange coupling on the idle end of the main crank shaft.

The compressor has two low-pressure cylinders, 12-in. diameter, one intermediate cylinder 8-in. diameter, and one high-pressure cylinder, 4-in. diameter, all with a common stroke of 7 inches, and delivers the air to any of the receivers, which are three in number, for starting, reserve-starting, and running respectively. The starting receivers are piped to starting valves on two of the engine cylinders, the other two cylinders automatically operating on oil as soon as the speed is sufficient to give the requisite compression temperature to the air for ignition of the oil spray. The engine can easily be started and run up to speed ready for the load within one minute by one man.

frames, the whole superstructure being built of cypress, and securely bolted to the concrete tank.

To the engine is direct connected a 500-kw., 4,200-volt, 3-phase, 60-cycle generator of Swedish General Electric make, excited by a 11.5-kw., 115-volt exciter. The leads from the generator enter the sub-station through a tunnel.

Sub-station.—The generator switchboard consists of one panel, upon which are mounted a.c. and d.c. voltmeters and ammeters, integrating and graphic wattmeters, frequency and power factor meters and synchroscope, one of each.

The main switchboard consists of ten panels, viz., two main oil switch, two transformer, five feeder, and one totalizing meter panel.

The generator bus-bars are connected to the main bus-bars through knife switches, so that the generator panel may be entirely thrown out when the engine is not in use. The generator is so arranged that it can be run in parallel with the main system through their own transformers.

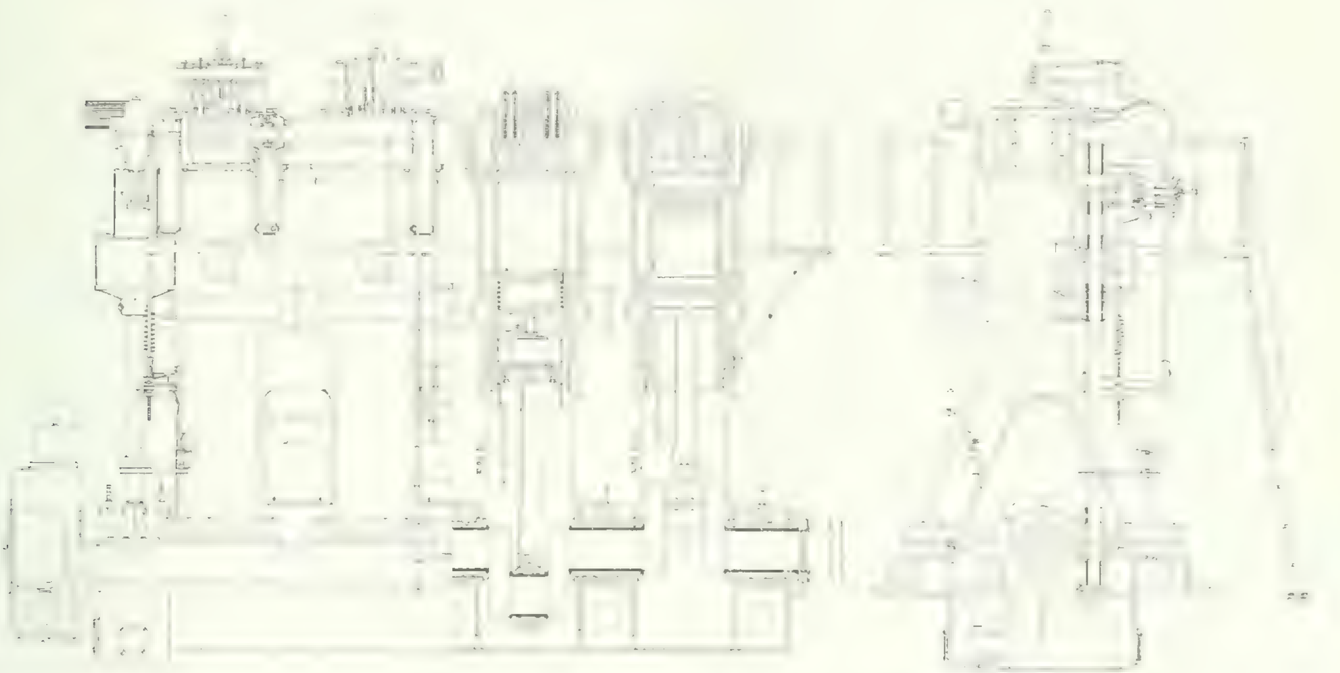

Fig. 3.—Elevations and Sectional Views of Engine.

The circulation of the cooling water is maintained by a rotary pump operated from the main shaft, the discharge being taken to the top of a cooling house mounted in a concrete tank in the yard. This tower is designed to avoid, as far as possible, the necessity of surrounding louvres structures to prevent waste by splashing, the water falling over stepped boards set in a series of A

The transformer room contains two 750 k.v.a. transformers with provision made for two more when needed.

Wm. Garnet and Sons, of Port Hope, Ont., were the contractors on the building. The engine was supplied by Willans and Robinson, Limited, Rugby, Eng.; the generator and exciter by the General Electric Company, of Sweden.

Recently many firms have transformed rope-driving into belt-driving systems, largely on account of the insufficiently criticized results of Kammerer. Experiments on a 200 horsepower plant are described. The ropes used for driving purposes are especially flexible. The efficiency of transmission has a mean value of 97.3 per cent. and increases with the load. Writing upon the subject in the *Zeitschr. Ver. Deutsch. Ing.*, lvii, 1911, H. Bonte says that few ropes are sufficiently stressed in practice. Rope driving properly applied is quite as efficient as leather belting, and probably more efficient than double or triple belts. It occupies less space and the initial cost is less.

At the Fosas mine in Sardinia a rather effective device is in use, permitting two buckets travelling in opposite directions to pass each other on the same rope. To the carrier of each bucket are attached 2 arms extending parallel to the track cable and above it. These arms are pivoted over the carrier, the one on the ascending side being kept elevated above the rope by means of a flat steel spring, while the arm on the descending side overlaps the rope and forms the track for the carrier coming in the opposite direction. The loaded descending bucket is, of course, placed at a higher level than the empty ascending one, enabling them to pass by means of the device described.

RESERVOIR STORAGE.*

By W. P. Mason,
Professor of Chemistry, Rensselaer Polytechnic Institute, Troy, N.Y.

At the outset it must be admitted that the advantages of water storage are many and the disadvantages but few. In those days when the expression "stagnant water" carried with it all sorts of ill-defined fears, the opponents of storage were easy to find, and their enthusiastic statement that "abundance of light and air is essential to the proper conditioning of water for human consumption" received very general support. He who drank of the rapid stream was accounted greater in wisdom than he who selected a less aërated supply.

It is now almost trite to say that still water, rather than running water, purifies itself the better, and it equally lacks novelty to point out that the more rapidly a stream flows, the sooner is its load of pollution delivered to the thirsty consumer. In that connection, let it be said that a great deal more depends upon the number of hours required for stream flow than upon the distance in miles between the intake and the source of pollution, and a concise statement giving information as to time of flow should appear in a report covering the sanitary survey.

Stagnation has its disadvantages, of course. Increase in color naturally follows if water be permitted to long remain in contact with a muddy bottom loaded with soluble extractive matters. Not only is damage to the water's physical appearance a result of such contact, but the material passing into solution is likely to furnish abundant food for those minute forms of life which carry objectionable tastes and smells to many public waters.

To the layman's ear the word "stagnant" has a most unpleasant sound, intimately associated with the production of disease; and yet its origin is innocent enough, viz., "stagnum," a piece of standing water, not running in a current or stream.

Pools so overloaded with vegetable growth, both dead and alive, as to be unfit for human drinking are plenty and they are commonly stagnant, but the ill-favored word does not properly apply alone to those; it is just as applicable to a water of crystal clearness resting upon a bed of sand.

The condition of "standing water" just referred to, namely, that of being overstocked with vegetable growths, is practically the only one toward which objection can point when considering the pros and cons of reservoir storage.

The word "vegetable" is here to be taken in its broad sense, as it should include not only those growths which would be recognized by the public at large, but also those of the minute world as well, which latter constitute one branch of that lake life known as "plankton."

As an instance of excessive overgrowth, a small lake could be named which is so loaded with dense vegetation that decay gets ahead of new growth, and the use of its water is productive of temporary diarrhœa. It is a stained water, but its color is not to be considered as a measure of its objectionable qualities for table use, as many waters of much darker tint are of excellent quality for such purpose. Color and fitness for drinking bear no relation to each other.

*Presented at the meeting of the Section of Physics and Chemistry of the Franklin Institute, January 29, 1914, and published in the April, 1914, Journal of the Institute.

It is true that colorless waters are now demanded by the people, and "meadow teas" are growing in disfavor, but that change in public opinion is of recent date and is not based upon established hygienic grounds.

The deepening in color of the lower layers of a water stored upon an unclean bottom; the encouragement of growths of small organisms producing taste and smell by reason of an accumulation of extracted food suitable for their development; and a deficiency in dissolved oxygen in the bottom levels, constitute the sum of objections that can be raised to the impounding of water, and they are much more than balanced by the advantages that accrue from such storage.

The pollution from shore drainage that reaches a reservoir water is likely to be naturally much smaller in quantity than that received by a flowing stream; nevertheless, very serious pollution may occur in concentrated form, even when the efforts of the caretaker are the most earnest. Thus, the writer has seen numerous loads of stable manure spread upon the very steep banks of a small, cup-shaped distributing reservoir. The intention in this case was good, and much pride was taken in the fine lawns of the waterworks park, but a better choice of fertilizer could have been made for such a location.

It is entirely possible to protect a reservoir, and to a great degree the watershed also, if careful policing of the district be established. Country towns situated upon the banks of streams tributary to the reservoir are the sources of greatest danger, and an earnest effort should be made to remove all privies, manure heaps, farm yards, refuse dumps, and other sources of pollution from draining into the stream or any of its feeders. This is sometimes difficult to accomplish completely, but a high degree of thoroughness can be attained by suitable and tactful management.

Board of health rules are expected to cover care of public watersheds, but rules and laws will not enforce themselves, and the city official is commonly at a distance and more interested in the distribution system than in that of collection. The most simple arrangement would seem to be to appoint a local physician in each town or village upon the watershed as the sanitary inspector for that particular district, and to give him authority to employ an intelligent laborer as a sub-inspector to do the necessary work under his direction.

The writer has found this arrangement both efficient and cheap. In one noteworthy instance, besides caring for the sources of pollution noted above, the sub-inspector's duty included the daily patrol of a mile of railroad track which ran along the border of the reservoir. This question of possible danger from railroad pollution has but recently been recognized. Although it is always well worthy of consideration, there is no question but that it greatly varies in importance with change in topography, soil, or season. Rocky, steep slopes are easily washed by the rain, and frozen embankments naturally fall into the same classification, while flat road-beds and sandy soils offer better chances for polluting material to be disposed of by natural methods.

Whatever the character of the road-bed, it should be the sub-inspector's care to remove all night-soil dropped from passing trains, and he should exercise greater vigilance in winter than during summer.

The physician-inspector would be in a position to know of cases of disease, such as typhoid, in his district and, being so informed, could take proper precaution against contamination of the public water, which act on

his part would be of vastly more practical value than a location of the trouble by some sanitary commission after an epidemic was well under way.

The greatest responsibility borne by the inspector, however, would be during periods when gangs of laborers were employed at construction work within the limits of the watershed. Should the workmen be many and the time of their remaining be two weeks or more, nothing short of incineration of all camp waste and night-soil should be demanded, and the utmost care should be taken that sanitary instructions were carried out to the letter. A Woodruff pit, which can be constructed in a few hours, would be suitable for a temporary camp; while, if something more permanent were demanded, a well-constructed incinerating furnace should be built.

When meadow lands are flooded, the extraction of food for plankton growth must of necessity take place, and we are forced to choose between stripping the proposed bottom or else depending upon the employment of some means of killing or removing the organisms that are likely to develop.

As to what could be done to rid a water of the odors due to algal and other growths, the outlook was not very hopeful previous to the appearance of the "copper sulphate process" proposed by Moore and Kellernan in 1904 (Bulletins 64 and 76, U.S. Bureau of Plant Industry).

The method of applying this chemical is simple enough, and its use is very efficacious. Bought in bulk, it can be had at about five cents per pound, and its distribution is readily secured by filling it into perforated buckets, or even bags, and towing the same by row-boat or launch over the reservoir surface.

Decided objection was raised against such a process of "disinfecting" a public water supply, and the opposition was especially marked in England, but the use of it is still with us and is likely to stay, for the reason that the "dose" is minute and is only occasionally required, that it is reliable in results, and that experiment has shown that it is not followed by the evil consequences predicted.

It must be remembered that it is not added to the water continually but is used only at stated and widely separated intervals, namely, at those times when the "crop" of minute organisms has become so well grown as to produce objectionable effect upon the water.

Perhaps one reason why the "coppering" of reservoirs has led to so much criticism is because of the dead fish that are to be seen after the chemical has been applied. When considering this effect upon fish life, one should bear in mind that the "dose" has of necessity to be applied uniformly over the surface of the water, and each acre of such surface presumably receives the same amount, irrespective of the depth of water that the acre covers. As a result, the shallow parts of the lake receive temporarily a greater quantity of the sulphate, per cubic foot of water, than do those which are deeper; again, the entire quantity of chemical intended for the whole body of the lake is delivered to a few inches of its surface layer; therefore, until diffusion has taken place, fish which chance to swim into such water receive a very concentrated dose and are likely to be affected by it. Distribution is complete by the time the water reaches the public mains, and, moreover, the minute dose used has been more or less completely disposed of through its action upon the organisms for whose destruction it has been employed.

In a paper before the Section on Hygiene of the Eighth International Congress of Applied Chemistry, 1912, Kellernan presented the following data:

Quantity of Copper Sulphate Required to Kill Various Forms of Odor-producing Organisms.

Copper Sulphate Required, Expressed as Parts per Million Parts of Water.

Anabæna	[illegible]	Kirchneriella	5. to 10.
Asterionella	.1	Leptomitus	.4
Beggiatoa	5.	Microspora	.4
Chara	.2 to 5.	Navicula	.07
Cladophora	1.	Oscillatoria	.1 to .4
Cladothrix	.2	Peridinium	2
Clathrocystis	.1	Scenedesmus	5. to 10.
Cœlosphærium	.3	Spirogyra	.05 to .3
Conferva	.4 to 2.	Ulothrix	.2
Euglena	1.	Uroglena	.05
Fragilaria	.25	Volvox	.25
Hydrodictyon	.1	Zygnema	.7

He adds a list of twelve genera of algæ that in his experience are causing trouble in reservoirs and ponds:

Number of Observed Cases.

Anabæna	27	[illegible]	[illegible]
Asterionella	9	Crenothrix	13
Beggiatoa	2	Fragilaria	19
Chara	26	Navicula	21
Cladophora	17	Oscillatoria	49
Clathrocystis	23	Spirogyra	43

Jackson claims that blue-green algæ will die if the water be "coppered" one part to five million. His dose for Mellosira or Synedra is one to two million, and he claims that the former gives no odor of growth, but only that of decay. He finds that coppering runs out certain forms of organisms and substitutes others by a sort of selective action, but those thus substituted are not likely to be odor-producers; and he further notes that, while "bottom" or decomposition odors are easily shaken out by aëration, "top" odors, viz., those of growth, have to be removed by filtering out the organism, or killing them by copper sulphate, or both. In his opinion, filtration of either type is effective for removal of odors of growth, but he believes that aëration would be worse than useless for living plankton, for the reason that the agitation would tend to mechanically release the oil causing the taste, which oil is not very easily oxidized.

Naturally the cost of treatment with sulphate of copper will depend in part upon the amount of the chemical that is to be used, which in turn is determined by the kind of organism that it is intended to kill; but it may be said that a mixed growth of Mellosira and Asterionella was removed from the Troy reservoir at an expenditure of 14.9 cents per million parts of water treated, labor included. The dose was one part of copper sulphate to 3,500,000 parts of water by weight.

In the article by Kellernan above quoted there are figures given indicating the safe limit for treating water with copper sulphate when certain fish are to be protected.

Copper Sulphate, Expressed as Parts, per Million Parts of Water.

Black bass	2.1	Pickerel	.4
Carp	.3	Suckers	.3
Catfish	.4	Sunfish	1.2
Goldfish	.5	Trout	.14
Perch	.75		

It must be noted that these figures assume a thorough mixing of the sulphate solution with the whole body of water. They would not hold for the unequal distribution and resulting local concentrations already mentioned.

In some reservoirs which have been formed by the extensive flooding of swamp bottoms there may develop objectionable growths of crenothrix, a general term denoting an aquatic plant which at times gives much trouble because of its tendency to develop in the street mains and

clog the pipes. It is often discovered quite unexpectedly, being dislodged by the current attending hydrant flushing or by the draft caused by fire engines. Dead ends are spots likely to harbor it, and its long, rusty filaments have been mistaken for horse manure.

There are three types of the growth, each possessing the peculiarity of precipitating from the water in which it grows its own particular metallic hydroxide. By far the commonest of the three is crenothrix kuhniana, which demands iron for its development and which deposits large amounts of iron hydroxide as the result of its growth. The iron required for growth must be in solution, and the quantity demanded would seem to be about 0.3 part of Fe per million.

In order that the iron may be in solution, we naturally would expect the dissolved oxygen to be low and the quantity of reducing agents, such as organic materials, to be high, and those are the conditions that we find in practice to be favorable to the development of the plant.

It is likely to be encountered in waters from swampy, peaty sources where dissolved oxygen is scanty and where the necessary iron in solution may be had. Driven wells in such localities frequently furnish it. Darkness favors its growth, and its development in city water mains is often excessive, resulting in a material reduction of the carrying capacity of the pipes. The writer has some doubt about the "manganese" variety of crenothrix being as rare as some think it is, he having found large quantities of manganese in a heavy Wisconsin growth. Beythien and others have, moreover, noted that the presence of manganese in water directly favors the growth of the ordinary form of crenothrix.

Beyond the mechanical stopping of street pipes, crenothrix is exceedingly objectionable to the laundry interests of the community, for the reason that its rusty filaments cause "iron stains" to appear upon white linen.

Removal of the iron by oxidation and filtration is the best guard against troubles due to crenothrix.

It must not be sweepingly assumed that all the "plankton" life is to be rated as uniformly objectionable; quite the contrary, as a reasonable degree of it acts as a distinct help in maintaining the safety of natural waters. Thus we find "bacteria eaters," such as many kinds of ciliated infusoria, rotifers, daphnia and the like, feeding upon minute germ life, and doing so to our great advantage.

To quote from a translation by Kuichling: "The question is, what becomes of the great quantities of offal and excreta, the many remnants of decaying plants, the refuse of communities, and the finely divided factory wastes of every description, which find their way into our streams, even under normal conditions, if a large portion thereof is not consumed by the aquatic detritus-eaters and the omnivorous fauna before settling to the bottom?"

With a view to avoid the troubles arising from the undue growth of taste- and odor-producing organisms, the stripping of reservoir sites and the removal of a portion of the upper soil has been advocated and carried into practice. This, of course, entails very great expense when the surface to be stripped is at all extensive, as in the instance of stripping the Nashua reservoir supplying Boston. At Columbus, Ohio, such work cost $159 per acre.

In their report upon the probable cost of stripping the surface soil from the Ashokan reservoir site, which is to hold the water supply for New York City, Messrs. Hazen and Fuller stated it would possibly reach the great figure of $5,000,000.

In view of the expense of such treatment for large reservoirs, the question is pertinent, "Does it pay?"

At Holyoke, Mass., the annual water report for 1908 says: "Great care had been taken in cleaning and stripping the reservoir by removing all vegetable and organic matter, thus lessening to a minimum the food supply for supporting living organisms in the water. The thorough cleaning of the reservoir has not been wholly successful, as an aquatic plant known as 'Chara' has grown and flourished in the reservoir all summer and imparted to the water a taste and odor that made it unfit for drinking or even for cooking purposes."

Mr. J. M. Diven ("American Water Works Association," 1908) has had interesting and contrasting experiences with both stripped and unstripped reservoirs:

The Elmira reservoir was as thoroughly stripped as possible; great care was taken to keep out the first washing from the drainage area and the muddy flood waters. There was little or no marsh land on the drainage area, the catchment area being seemingly ideal. The reservoir was clean and clear; on the sides the slopes were abrupt, and there was very little shallow water.

"At Charleston, S.C., the drainage area was largely swamp, and there was much decayed vegetable matter on all of the area drained, the water being decidedly peaty. The reservoir covered a large surface, was shallow, and absolutely unstripped or even cleared. Much of the land flooded was composed of black muck or decayed vegetable matter.

"In the first case (Elmira) the conditions were at the first satisfactory and the water good for several years. But trouble from algal growth came in time and has steadily grown worse, in spite of strenuous efforts to remedy the condition.

"The second case (Charleston) was troublesome and unsatisfactory from the first, but has somewhat improved and promises to continue to improve."

The writer's experience leads him to advocate the expenditure of comparatively little money in the preparation of sites for large storage reservoirs, for the reason that, although thorough stripping will likely give immunity from algal growths for some years, yet freedom from the occurrence of taste and odor in the stored water may not last for long. Sooner or later there will be carried into even the most carefully cleaned reservoir enough food material to sustain a plankton growth of a density governed by the local conditions. Broadly speaking, an "old bottom" is better than a new one, because it is likely to contain less plant food; but the rule has many exceptions.

Even natural lakes are frequently seen "in bloom"—that is, loaded with minute life—and they so remain for a period during which their waters are not acceptable for domestic use. The character of the tributaries must be considered as well as the nature of the bottom of a proposed reservoir, for it is manifestly loss of money to improve the latter if the former can quickly replace much of what has been taken away.

For the sake of general appearances, if for no other reason, trees, shrubs and bushes should be removed. Dead, standing timber and fallen logs are most unsightly and are very likely to produce complaint from the visiting public. In other words, the reservoir site should be cleared and grubbed, with, of course, entire removal of every vestige of human habitation; but beyond that it scarcely pays to go. The portion of the flooded land lying between high-water and low-water marks should receive especial attention, for the reason that during the

periods of its exposure it is capable, if uncared for, of presenting an unpleasant appearance and provoking adverse criticism; with the further objection that heavy weed growth may develop if it be long uncovered, which growth will contribute toward the production of taste and smell when the water again covers it.

In an instance where it was proposed to restore a dam that had been out of repair for over fifty years the writer advocated the cutting off of the standing dead timber at the existing water level before closing the breach, in order to insure a better looking sheet of water when the reservoir filled. This was for appearances only, as all extractive matter had been leached out of the old vegetation long before.

Aëration, filtration, and the judicious, occasional use of copper sulphate constitute the processes at our disposal for combating the annoyance arising from algal growths, and their use will give greater satisfaction than the expensive stripping of reservoir bottoms, a treatment which was so frequently advocated in the past.

Dr. A. C. Houston, of the London Metropolitan Water Board, has undertaken some very extended researches upon the question of water purification as a result of storage. He found that in stored Thames water the death of typhoid bacteria took place rapidly, although the rate varied with the temperature of the water. In cold water they lived longer than in warm, and 50° F. seemed to be a critical point above which their mortality rate was much increased.

In his 7th Research Report, Houston states that typhoid bacilli lived in stored raw Thames water for the following lengths of time: At 32° F., five weeks; at 41° F., four weeks; at 50° F, three weeks; at 64° F., two weeks.

Even these figures do not tell the entire story. Put in more detail they read:

	At start.	One week.	Two weeks.	Three weeks.	Four weeks.	Five weeks.
32° F.	[illegible]	[illegible]	[illegible]	[illegible]	34	[illegible]
41° F.	103,328	14,894	26	6	3	—
50° F	[illegible]	[illegible]	14	3	—	—
64° F.	103,328	39	3	—	—	—

He concludes: "It is difficult to escape the belief that thirty days' storage of river water is tantamount to sterilization, so far as the microbes associated with water-borne epidemic disease are concerned."

When experimenting with an artificially infected water to determine the effect of storage upon the typhoid bacillus, Dr. Houston felt that any error so introduced was upon the side of safety, because he had previously shown the "cultivated" typhoid organism to have a greater longevity than the "natural" *Bacillus typhosus*. In his report he dwells at length upon the advantages to be derived from "adequately storing the *raw* impure river waters." Even if there were no economic reason for storing a river water before rather than after filtration, yet it would be well to follow that course, aside from any question of algal growths, for the reason that sedimenting silt greatly assists in bacterial removal. Placing the word "raw" in italics was, therefore, a matter of good judgment.

Dr. Houston adds: "I am well satisfied that a well-stored, rapidly filtered water is likely to be safer than an unstored, slowly filtered water."

It is possible to go even further than this, for one can see how dangerous it might be to deliver, directly to the consumers, the water of a small and apparently pure mountain stream. The dejecta of a single typhoid carrier would render so small a volume of water highly infectious, if no storage intervened, and an outbreak might follow, such as occurred at Plymouth.

Although Dr. Houston is doubtless sound in his judgment that a great measure of safety will result from four weeks' reservoir storage of a polluted water, yet we must be assured that the period of storage is real and not simply apparent; or, in other words, we must know that *all* of the water really does remain in the reservoir for the specified length of time before it is used for public consumption.

Where the inlet and outlet of a reservoir are near together, as is not uncommonly the case, it makes but little difference what the capacity of the total storage may be; the water simply slips in and out again with practically as little stay as though the reservoir was a standpipe.

If the lake be long, narrow and deep, and all of its water be obliged to traverse its entire length before being taken for supply, then the conditions would appear ideal for purification of the inflowing water before the outlet was reached, and yet even under those excellent conditions it is possible to have introduced unexpected and upsetting factors, as is instanced by the history of the typhoid epidemic at Auburn, N.Y.

Lake Owasco is one of the so-called "finger lakes" of western New York. Its length is about ten miles, breadth one mile; its watershed is about 190 square miles, and its depth is about 175 feet. A small stream enters its head, and Auburn, a city of some 30,000 inhabitants, has an intake located at the north end or foot of the lake and forty feet below the surface. The temperature of the water at that point in May, 1913, I found to be 42° F.

The peculiar feature of the case which has special interest here is the possibility of polluting material of fecal character being transported from a village near the head of the lake, down the inlet stream, and then northward for the entire ten miles of the lake's length to the Auburn intake situated near the lake outlet.

We have all faithfully held to the dictum that "sedimentation and time" are the great purifying agencies upon which to rely for the natural improvement of a once polluted water; and it takes a good deal of evidence to persuade us that sewage of a small village could make the trip down such a lake in a length of time and in such a manner as to dangerously affect the water of the lower end. Experimental data, however, have been secured showing that such a result can actually take place. Investigation showed the following facts: The village sewage was, of course, small in volume, but during the winter months it was deposited at several points upon the banks of the inlet stream and there it collected in a more or less frozen condition until the occurrence of the spring thaw, at which time there was opportunity for much accumulated fecal material to be washed into the lake in a state of suspension. There was also a chance of its being actually ferried upon cakes of ice, for the reason that certain privies were located upon bridges and fecal matter was dropped upon the very centre of the ice-covered stream.

As stated, the shape of the lake is long and narrow and its axis lies north and south. It must be further noted that the prevailing wind is from the south, with a tendency to blow the surface water directly toward the city intake at the north end.

By means of triangulation and the use of floats constructed so as to be moved by water currents existing at the different depths of from five to twenty feet, it was ascertained that the upper strata of water moved northward with the wind, as would have been expected. The

rate of this movement being ascertained, it was found that with relatively light winds the movement of the water down to a depth of five feet amounted to about three per cent. of the wind movement, while at lower depths this water movement diminished to as low as three-quarters of one per cent. of the wind movement. Thus, to quote from the figures of Mr. Ackerman, who made these tests, with a wind movement of six miles per hour the percentage which the water movement was of the wind movement was as follows: At 5 feet depth, 3.2 per cent.; at 10 feet depth, 1.74 per cent.; at 15 feet depth, 0.87 per cent.; at 20 feet depth, 0.75 per cent.

With a higher wind velocity the water also travelled with greater velocity, but its movement was then not so large a percentage of the wind movement. Thus, with a wind blowing 17 miles an hour the water movement at a depth of five feet amounted to but one and a quarter per cent. of that of the wind. From these data it was easy to calculate that pollution entering the head of the lake could make the trip to the foot of the lake in three days or less.

Knowing, as we do, from Dr. Houston's experiments, that cold water below 50° F. will favor the longevity of the typhoid fever bacillus, it is easy to see how entirely possible it would be for living germs to reach the intake in dangerous condition.

It will be noted how striking is the resemblance which some features of this case bear to the classic instance of the outbreak of typhoid fever at Plymouth, Pa., where the whole trouble came from the dejecta of a single individual being thrown out upon a hillside where it froze and accumulated for weeks and finally, upon the coming of the thaw of spring, was washed into a stream tributary to the city reservoir. This sudden washing of accumulated fecal material furnished in both of these instances a volume of pollution out of all proportion to the amount which would be daily derived from the contributing population during ordinary times of fair weather, and as a result it overtaxed and broke down nature's ordinary means of purification and protection.

There is no question but that this particular case, showing, as it does, the dangers that may arise from such winter accumulation, and showing further the possibility, under favorable conditions, of the transportation of such material over considerable distances in a lake, will cause many of us to materially amend our notions about the dependence to be placed upon lake and reservoir storage as a means of protection against the evils following water pollution. We should not trust to simple storage without a thorough knowledge of just how it is being accomplished. The writer has in mind an instance of a large lake some five miles in length which has a stream entering within one mile of a city intake, and, because of the entering water having a low specific gravity, there is a possibility of its flowing over the surface of the lake toward the intake whenever the wind is in the right direction. The great length of that lake is, under such circumstances, of small value for purification purposes.

All of this certainly goes to show that we should be cautious about banking too strongly upon the efficiency of reservoir purification under all circumstances, and it demonstrates the necessity of our being well acquainted with the conditions surrounding each individual case before venturing an opinion on the matter.

It should be noted here that, in judging of the bacterial efficiency of lake or reservoir storage, the interpretation of the results of an examination may be obscured by an increase in the total count of bacteria reported due to the disturbing influence of the spring or autumn "turnover."

In conclusion, permit a word to be added concerning the value of storage as a protection against spreading disease through the use of an "emergency" water supply. The underwriters very properly insist upon a sufficient fire service, which shall be available in the event of a temporary breakdown of the regular distribution system. It too often happens that upon such occasions a very inferior water is supplied by the "emergency intake," and as a result of its use there follows an outbreak of typhoid fever. Commonly, some old intake is allowed to remain in place for "emergency service," when pollution of the former supply has so grown in intensity as to force the authorities to seek a new source for public water.

Further fouling of this old supply goes on progressively as population increases, until after some years the water becomes practically dilute sewage. Suddenly some accident to the regular water system induces the authorities to open the old gates, and the result may be imagined.

Such has been the history of typhoid epidemics in a number of cities.

Storage for a sufficient length of time, supplemented, if necessary, by an appropriate dose of bleaching powder, will render even a poor water acceptable for emergency uses, and the reservoir capacity for such storage need not be large.

MILL CONSTRUCTION FOR ABITIBI PULP AND PAPER COMPANY.

It is proposed to have ready for occupancy by June 1 the paper mill building of the plant of the Abitibi Pulp and Paper Company at Iroquois Falls. It will be 500 feet in length and nearly 300 feet in width, being much larger than any of the other buildings now clustered around the edge of Iroquois Falls. It will be like the other buildings, of solid concrete construction, absolutely fireproof. Forty thousand cords of pulpwood are piled on the banks of the Abitibi and Black Rivers and tributaries waiting to be floated down the rivers to the falls when the ice leaves. It has been decided to keep a gang of 250 men at work in the bush during the summer months cutting wood on the large reserve of the company. The total now cut awaiting the spring freshets will be increased by thousands of cords of settlers' pulp, to be shipped in by rail. At the plant at Iroquois Falls 475 men are now employed, with 250 men in the bush and at the Couchiching Falls dam.

Contracts are being signed for the equipment of the paper mills, while contracts for the paper machines have already been signed. These will consist of one 204-inch machine, manufactured by Walmsley, of London, England; two 188-inch and one 158-inch machine, manufactured by Pusey and Jones, of Wilmington, Delaware.

American copper mines turned out 218,579,133 pounds last year, or 1,901,380 pounds less than in 1911, but the value ($36,065,556) was $8,505,482 greater.

The London *Standard* states that a new alloy of exceptional lightness, considerable mechanical strength, and freedom from electrolytic action, is stated to be gaining popularity in British engineering circles. It is named "Ivanium." This alloy, obviously one of aluminium with one or more metals occupying positions, relatively near aluminium in their electrochemical properties, is only 2½ per cent. heavier than pure aluminium. It is stated to have the property of retaining its hardness after being subjected to heat, and of being non-magnetic. When polished, the surface remains bright indefinitely. Castings made in ivanium are stated to be equal in finish to the finest gun-metal. The alloy does not clog a file, and it can be screwed, tapped, milled and soldered with ease. Joints soldered together are stated to be as strong as the original metal. The melting point is low, about 300° C., and the alloy is claimed to be a useful deoxidant.

THE MEXICAN OIL INDUSTRY.

With the present complications which pervade Mexico, and particularly the vicinity of Tampico, it is very gratifying to be assured that the oil operations there are well removed from danger. The safety of workmen and of storage has been given much attention by Secretary of State Bryan, and his satisfactory assurances to ambassadors of other countries that no danger to the oil operatives ensued, brings an atmosphere of relief.

There are many interesting particulars connected with the Mexican oil industry. Some of them were given in a lecture delivered recently by Mr. R. P. Brousson, in England.

Dealing first with historical features, he mentioned that some oil-springs near Papantla were discovered in 1868 by Dr. Autray, who tapped them by tunnelling into the side of the hill from which the oil exuded. He set up a still, and for some time supplied the local demand for illuminating oil, but the enterprise did not prove profitable, and was eventually abandoned. Many more or less productive wells were drilled by different concerns between 1880 and 1904, but production on a really large scale did not commence until 1907, when Mexico first figured in the world's production statistics with 1 million barrels. At the present time the whole production of the country, which last year amounted to 23 million barrels, comes from twelve fields, six of which, controlled by the Pearson interests, account for about half the total output. Mexican oil is of an asphaltic nature, and that obtained from the north of Tampico has a high specific gravity, and is of such high viscosity that it cannot be economically pumped through pipe-lines. The quality of the oil, however, seems to improve more and more towards the south; at the southern end of the northern belt, for instance, an oil is found with a specific gravity of 0.894, and a viscosity of 143 seconds (Redwood) at 100 deg. Fahr. In the Isthmus of Tehuantepec, or southern belt, representative oils have specific gravities of 0.881, 0.852, and 0.816, with viscosities of 108, 50, and 30 seconds, respectively. These oils contain large quantities of motor spirit and illuminating oil, and some of them are practically free from asphalt, a feature which greatly facilitates the manufacture of high-class lubricants. The Mexican Eagle Oil Company have chiefly devoted themselves to the southern regions, and have control of a very large quantity of middle-grade crude oil, together with practically all the fields producing the lighter oils. Their large refinery at Minatitlan is capable of dealing with 1,400 tons of crude petroleum a day, producing from it motor spirit, burning oils, lubricants, fuel oil, paraffin wax, and asphalt. Another refinery is under construction at Tampico, and will be in partial operation by June of this year; when completed, its capacity will be 4,000 tons a day. The oil is transported by the Eagle Oil Transport Company, which company has twenty large tank steamers, either in service or under construction. Ten of these vessels, among which is the San Fraterno, have deadweight capacities of over 15,500 tons. The lecturer referred to the very interesting method of loading these vessels at Tuxpan, where the water is too shallow for them to come in close to the shore. Pipe-lines have accordingly been laid on the bed of the sea for a length of about 1½ miles out, and these pipes are connected by flexible hose to the steamers lying at ocean moorings. By this means three or four vessels can be loaded at once from the storage-tanks and pumping-station on the shore. During 1913 more than 200 steamers were loaded in this way in an average time of 2½ days each. The lecturer concluded his interesting discourse by pointing out that the very rapid development of the oil resources of Mexico that has taken place, up to the present, has been confined to the State of Vera Cruz. He, therefore, thought that, as other States are known to be petroliferous, it was safe to assert that the oil industry of Mexico is now only at the beginning of its ultimate prosperity.

RAIL STATISTICS IN THE UNITED STATES, 1913.

Statistics have been compiled by the Bureau of Statistics of the American Iron and Steel Institute showing the production of rails in the United States during 1913, and comparing this production with that of foregoing years.

In 1913, there were produced 3,502,780 tons of rails of all kinds, against 3,327,915 tons in 1912, an increase of 174,865, or 5.2 per cent. Included in the total for 1913 are 195,659 tons of girder and high T-rails for electric railways, against 174,004 tons in 1912 and 205,409 tons in 1911.

The most significant feature of the bureau's report, is the comparison of manufacture of Bessemer and open-hearth steel rails. In 1906, when the maximum rail production was reached, the production of Bessemer steel rails amounted to 3,791,429 tons, while in 1913 the production had decreased to 817,591. During the same period the production of open-hearth steel rails had increased from 186,413 tons in 1906 to 2,527,710 tons in 1913, which is an increase over 1912 of 422,566 tons, or 20 per cent. Of the total production in 1913 about 72.16 per cent. was rolled from open-hearth steel, about 23.34 per cent. from Bessemer steel and about 4.50 per cent. from electric steel, old steel rails and renewed rails.

In 1913 nearly 29.9 per cent. of the rails weighing less than 50 lb. per yd., nearly 48.7 per cent. of the rails weighing 50 lb. and less than 85 lb., and over 87.2 per cent. of the rails weighing 85 lb. and over, were rolled from open-hearth steel, while in the same year nearly 41 per cent. of the rails weighing less than 50 lb. per yd., over 44.8 per cent. of the rails weighing 50 lb. and less than 85 lb., and nearly 12.1 per cent. of the rails weighing 85 lb. and over were rolled from Bessemer steel. In addition, in 1913, over 29.1 per cent. of the rails weighing less than 50 lb. per yd., over 6.5 per cent. of the rails weighing 50 lb. and less than 85 lb., and less than 1 per cent. of the rails weighing 85 lb. and over were rolled from electric ingots and old steel rails or were renewed rails.

PROGRESS OF GREATER WINNIPEG WATER SUPPLY LINE.

The preliminary work on the water supply line from Shoal Lake to Winnipeg has been thus far accomplished with general satisfaction. The frozen ground facilitated the making of accurate surveys and the locating of the line approximately on the preliminary alignment through a country almost impenetrable except in winter. A section 37 miles long was run between two points 38 miles apart, with a deviation of not more than 3 miles from the air line and with a perfectly uniform grade of 0.7 ft. per thousand except for two small river crossings.

The location is through a country about 60 per cent. of which is covered with small timber. Half the distance is in muskegs. The concrete aqueduct will be uniformly covered by a fill 4 ft. deep, and it is believed that the invert will at all points be in hard ground below the swampy stratum. A contract of about $1,000,000 has already been awarded for the construction of 96 miles of standard-gauge service track for the construction of the pipe line. This track will be built in accordance with standard specifications and will have 60-lb. rail on rock or gravel ballast, qualifying it for permanent service. Construction is being advanced on a $25,000 telephone line connecting the engineering and construction camps with the offices in Winnipeg.

The Canadian Safety Engineering Bureau has been opened in the Mail Building, Toronto, under the management of Mr. Riley Schenck, for the purpose of specializing in the scientific prevention of accidents and fires.

THE SIGNIFICANCE OF B. COLI IN WATER EXAMINATION.

By Joseph Race, F.I.C.,
City Bacteriologist, Ottawa, Ont.

WHILE too much importance has been attached in the past to the presence of B. Coli in water used for domestic supplies, it is regrettable that the pendulum is now showing a tendency to swing too far in the opposite direction. The paper of Geo. A. Johnson (Proc. Amer. Waterworks Assoc. 1913, pp. 399-455), of Johnson and Fuller, New York, is an illustration of this movement. The all too common practice of using arbitrary and empirical methods in the bacteriological examination of water is partially responsible for the present *status res*, and in this regard bacteriologists have only themselves to blame. As will be shown later, the mere presence or absence of B. Coli in an arbitrarily fixed amount of water may have no significance when considered without regard to other circumstances; and in attempting this we are merely opening the way for criticism. The Committee on Standards of the American Public Health Association (1912) evidently recognized the futility of such procedure when they recommended that quantitative estimations should be made of B. Coli. They add: "Qualitative results, when viewed superficially, may seem easier to obtain than, and quite as conclusive as, quantitative results; but detailed evidence shows that in general the quantitative tests are by far the most fruitful source of information." It would appear that the Committee might have gone further and deprecated the use of qualitative tests except under extraordinary circumstances. This procedure has also had a deleterious effect on those connected with sanitary work, and who, by reason of their lack of familiarity with the technique employed have accepted this sophism. The author believes that, even with all the assistance that quantitative methods of examination afford, it is often difficult to give a sound opinion on the hygienic quality of a water supply, and that it would be folly to revert to the older methods.

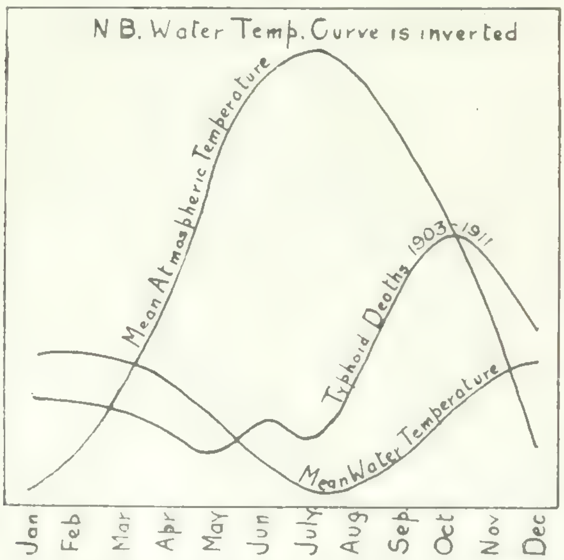

Fig. 1.—Showing Typhoid Deaths in Ottawa, 1903-1911.

There are many points of difficulty surrounding the significance of B. Coli, and on several of these the present knowledge is very meagre. Almost everyone is aware that B. Coli is common to the excreta of nearly all the higher and lower animals. In cold-blooded animals the occurrence is less constant, and more or less discordant results have been obtained. Dr. Amyot (Trans. Am. Pub. Health Assoc., 1901), concluded that B. Coli is not normal in the intestines of fish, and that when present it is due to the polluted environment. The tendency among animals generally is for B. Coli to become rarer as the zoological type becomes lower. None of the lower types, however, are susceptible to typhoid fever, man being alone in this respect, so that there is a possibility of having B. Coli unaccompanied by B. Typhosus. This B. Coli has, therefore, no significance.

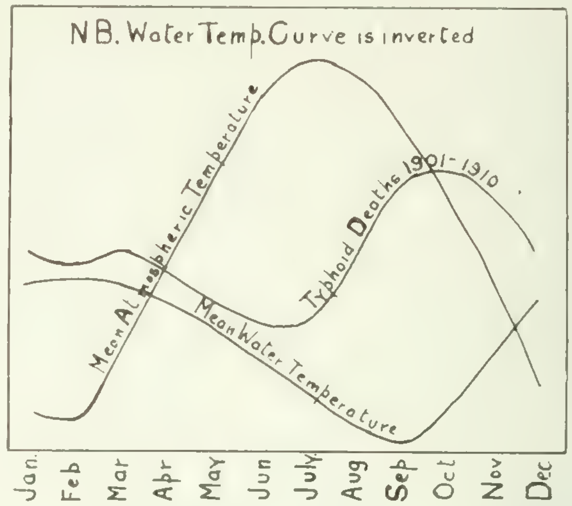

Fig. 2.—Showing Typhoid Deaths in Toronto, 1901-1910.

In reference to the B. Coli present in a water supply and due to human sources, it is important that information should be obtained regarding the total population on the watershed, the prevalence of typhoid and the probable period elapsing before the diluted sewage reaches the water services of the town under consideration.

The population is comparatively easy to obtain, and the typhoid death rate can, in most cases, be calculated from past records. In addition to the mortality, however, the case incidence should also be considered, as this has an important bearing on the probable ratio of B. Coli to B. Typhosus by its influence on the number of carriers. In Great Britain and certain portions of Europe the incidence is much lower and the case mortality higher than on this continent, so that the ratio of B. Coli to B. Typhosus is entirely different. It is possible that this ratio is ten times greater in North America than in Europe, and much greater significance ought, therefore, to be attached to B. Coli here.

The period elapsing between the discharge of the sewage and the withdrawal of the water is the most important factor, and in this connection the temperature of the water must be considered. Typhoid bacilli, in the absence of suitable food material, find an unsuitable environment in water, and, the cell energy being entirely of a katabolic nature, they die rapidly. It is obvious that this increases with the period of storage, and a consideration of the mechanism of the process also leads to the conclusion that the katabolic wasting increases with rise in temperature and vice versa. Dr. Houston and others have supported this hypothesis by numerous and conclusive experiments. It is important, therefore, that the bacterial contamination should be considered in its relation to the water temperature, and this leads to the conclusion that B. Coli should be regarded as having greater significance in winter than in summer. In the diagrams

illustrating this point the temperature curve has been inverted so as to conform with the viability of typhoid in water. In both the Ottawa and Toronto diagrams the typhoid death curve and the inverted water curve show a noticeable parallelism in the winter months, and as it is during these months that outside cases are at a minimum, the typhoid incidence is probably water-borne. The plotted figures for Toronto before and after the operation of the filtration plant show that it is this winter rate that has been reduced, whilst the summer prevalence, mostly due to imported cases, has remained unaffected. In Ottawa, with efficient sterilization with hypochlorite, only

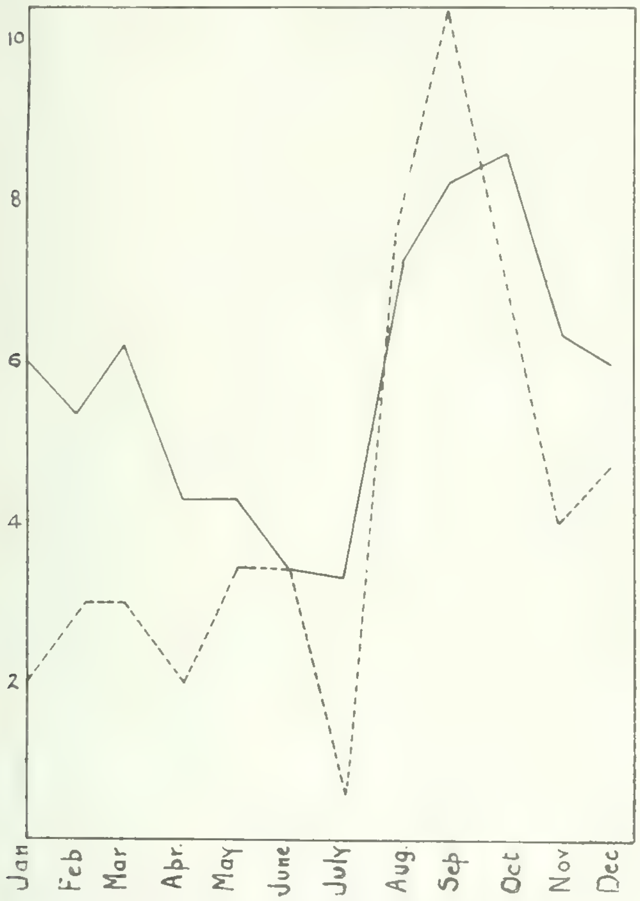

Fig. 3.—Typhoid Deaths in Toronto.—(Period 1903-11, before filtration, shown by full line; 1912-13, after filtration, by dotted line.)

one case of typhoid has been reported for the first four months of the present year. These results show what can be accomplished by water purification, and also that the significance of B. Coli must not be considered in an arbitrary manner.

Attempts have been made to belittle the value of the B. Coli test because the B. Coli content of the water supplies of certain cities did not bear a constant relation to the typhoid death rate. In such statements the sources of the typhoid incidence are not stated, and this, in many cases, may lead to erroneous conclusions. From the above remarks it is not to be expected that even typhoid rates due to water will closely correspond with the B. Coli content; all that can reasonably be anticipated is an approximate agreement. Cities with high B. Coli contents will tend, *cæteris paribus*, to high typhoid rates and the removal of B. Coli to decreasing rates. Let everyone remember that the B. Coli test is not a positive test for the presence or absence of pathogenic organisms, but an inferential test of danger and of potential injury to public health.

EARTH ROAD CONSTRUCTION.

THE following paper on the construction of earth roads was read by Mr. J. D. Robertson, Provincial Engineer of Highways for Alberta, at the 5th annual convention in March of the Alberta Association of Local Improvement Districts and Rural Municipalities:—

The necessity of permanent road construction in this province is becoming more noticeable each year. A few years ago, when the country was more sparsely settled, the old natural trails answered very well indeed and even now, with the increased traffic, these trails, especially in the southern portion of the province, where the soil does not retain the moisture to any great extent, hold up under heavy traffic, but where the soil is of such a nature that it retains the moisture we find it necessary to grade the road, construct side and offtake ditches so as to remove the surface water from it, but in doing this, if we are not very careful, and even with the greatest care, we leave the road with an inferior wearing surface to that of the natural top soil with its mat of roots. This is the problem we have to face as the country settles and traffic increases. It is necessary to adopt a system of road construction whereby a wearing surface will be obtained, that when properly maintained, will reasonably withstand heavy traffic. This result would no doubt be very easily obtained in many provinces of the Dominion but Alberta being an entirely agricultural province, and the soil being the very best for farming purposes, it is about as poor for road construction as it is good for agricultural purposes. We, therefore, will almost entirely have to depend on earth roads for some years to come, and should make up our minds to be content with them, for the best we can expect is possibly to top-dress with gravel or other material of a similar nature, a few earth roads, that will present a fair wearing surface where traffic is heaviest. But how much of this class of work can be expected when there are about 150,000 miles of road in the settled portion and about 400,000 miles of road allowance in this entire province?

You who have followed any of the reports, published by the Good Roads Congress or such like, especially in the east, will no doubt have noticed that the one thing they all agree upon is that earth roads are no good, and then go on and discuss macadam and other methods of road construction. In this province, instead of assuming their attitude, we have to build our roads with material we have at hand and in doing so, I think it would be safe to say the 95% of the roads constructed for years to come will be classed as earth roads.

In construction of earth roads there are at least three points which we should always bear in mind: (1) Proper drainage, (2) easy grades, (3) betterment of the road surface. The prevailing defect in earth roads is poor drainage and this defect is the first one which should be remedied. Drainage is for two purposes: (1) To remove water due to rainfall, and (2) to remove water which reaches the road by seepage from adjoining low wet land and which the road surface absorbs from underneath. To obtain the best results in surface drainage, I do not consider the side ditches should be over 24 feet from centre to centre of ditch and the roadway 16 feet in width with a crown of one inch to the foot. There are often opinions expressed that this is too narrow. I will grant that on a road leading into an important business centre, where the traffic warrants it, and 18-foot or 20-foot roadway is preferable, but the difference in the cost of maintenance of a 16-foot and 20-foot roadway is so great that, where

the traffic does not absolutely warrant the extra width, a 16-foot roadway is much more satisfactory as it is more liable to be kept in good condition.

Although the grade line of a road is very important, and a grade should not exceed 7% or where at all possible to obtain it, an easier grade should be found, still the grade line of the side ditches is much more important. How often have you noticed, especially where the country is slightly rolling and the work is done with a road grader, that great care is taken to carry the ditch through with a uniform depth. The bottom of the ditch is therefore the same distance below the surface of the ground, across the slight depression, as across the adjoining higher ground. The result is self evident, and after every fall of rain the side ditch instead of being a benefit to the road is a detriment. It would have been better not to have a ditch at all, for without the ditch the water would likely have run off, but the ditch prevents this and holds the water until it soaks into the road and forms a mud hole. Therefore, in my opinion, the grade line of the side ditches is by far the most important feature in earth road construction.

The next point that should be taken into serious consideration is the construction of offtake ditches. There cannot be too many of these. It is a poor policy to put in offtake ditches at long intervals and carry the water through the side ditches along the road. The quicker it is taken away from the road the less chance of injury to the road bed.

The same may be said about culverts. Where the road runs across the general slope of the country frequent culverts are necessary, it being a detriment to carry the water any distance along the ditch on the upper side of the road, for if this is done a large percentage of the water never reaches the culverts but filters under the roadbed and the consequences are soon apparent. Again in the case where the road follows with the general slope of the country, if the slope is too great the flow of water cuts away the roadbed and very often the ditches become so deep and the road so narrow that it is dangerous for traffic and, if the slope is not sufficient to carry the water away freely, it seeps under the roadbed, which is ruinous. In the first instance offtake ditches are required to reduce the volume of water that passes through the side ditches, and in the second instance they are required to remove the water more quickly from them.

Surface drainage is very often greatly interfered with by driveways leading into private grounds, or what we might call farm crossings, and especially if they are put in during a dry season of the year. They very often consist of a few poles thrown in the side ditch and covered with earth or possibly a load of manure or straw, in either case forming a dam. Of course, no doubt there are a great many who construct suitable crossings and it is to be hoped that the wisdom shown by them will lead others to follow their example.

There is one other point I would like to draw your attention to and that is the size of culverts used. The general tendency is to put in culverts which are too small to carry the water away freely, and in many places I have noticed the water level with the roadbed on the upper side of the road and the culverts running full. Too great care cannot be taken in putting in culverts of a proper size.

When it is desired to top dress an earth road with new material, care should be taken to secure it from the best available supply. River washed gravel is of very little use, as the pebbles are worn smooth and all the fine binding material has been removed by the action of the water. Even if clay or loam were mixed with river gravel, owing to the smoothness of the pebbles, it would not be nearly as satisfactory as material obtained from a gravel pit. Pit gravel frequently contains too much clay or earthly matter. Also very often the pebbles are of a uniform size, which is not suitable. The best pit gravel for road purposes should be composed of pebbles varying in size up to about 2½ inches in diameter and enough clay for a binding, so that the material may bond readily and if two layers are used the coarse material should form the bottom layer, then if there is sufficient binding in the material the finer particles will be washed down, filling the voids and good results will be obtained.

Top dressing 12 feet wide, averaging 4½ inches, would run about 880 cubic yards per mile and with a haul of one mile would cost $575 per mile in place with a three-mile haul would cost $1,000 per mile, with a six-mile haul would cost in place $1,750 per mile. This does not allow any charge for gravel, which might run as high as 25c. per cubic yard if obtained from a gravel pit of commercial value, nor does it allow any charges if shipped by rail, either for the extra handling or freight. In this connection I might state that no attempt should be made at top dressing a road until it is first properly crowned and ditched.
